Abstract

Background: Hospitalization poses significant psychosocial challenges for children, including anxiety, emotional distress, and disruption of daily routines. While animal-assisted therapy has shown benefits, practical barriers such as infection control concerns and inconsistent availability limit its implementation in pediatric wards. Social robots have emerged as a promising alternative, but evidence on their psychosocial impact in pediatric settings remains limited. LOVOT is a companion robot designed for emotional engagement through warmth, softness, and nonverbal interaction; however, no studies have examined its effects in pediatric health care.

Objective: This exploratory study aimed to assess the perceived impact of LOVOT on hospitalized children, their caregivers, and health care staff in a pediatric ward.

Methods: This prospective observational study was conducted in a pediatric ward at Hyogo Prefectural Amagasaki General Medical Center, Japan, from May 2024 to March 2025. Two LOVOT units were permanently installed in the playroom for free interaction. Caregivers (n=110) and health care staff (n=32) completed postintroduction questionnaires with retrospective ratings of perceived change using 5-point Likert scales (1="much worse" to 5="much better," with 3="no change" as the baseline). Free-text responses (n=91) were analyzed using automated emotion classification. One-sample 2-tailed *t* tests or Wilcoxon signed-rank tests compared ratings against the baseline, with false discovery rate (FDR) correction for multiple comparisons.

Results: All 10 caregiver-rated and 11 of 12 staff-rated outcomes showed significant perceived improvement (all caregiver items FDR $P<.001$; staff items FDR $P\leq.02$; the workload item was not significant, $P=.37$). Mean ratings ranged from 3.28 to 4.62 on the 5-point scale (baseline: 3="no change"). The largest perceived improvements were reported for children's enjoyment of hospital life (mean 4.47, SD 0.62), adaptation to hospital life (mean 4.10, SD 0.70 to mean 4.28, SD 0.63), and stress and anxiety reduction (mean 4.17, SD 0.76 to mean 4.19, SD 0.64). One-sample effect sizes ranged from medium to very large (Cohen d=0.53-2.67); however, because these were calculated against a fixed neutral baseline rather than a control group, they should be interpreted cautiously. Ratings from caregivers and staff showed strong agreement on 4 of 5 matched items. Notably, no detectable increase in staff workload was observed (mean 3.09, SD 0.53; $P=.37$), supporting implementation feasibility. Qualitative analysis revealed predominantly positive responses, with joy as the dominant emotion (mean probability 88.7%, 95% CI 86.8%-90.6%).

Conclusions: This study provides preliminary evidence that a companion robot (LOVOT) may positively impact hospitalized children, caregivers, and health care staff across multiple psychosocial outcomes without a detectable increase in staff workload. The low response rate and reliance on retrospective self-report limit generalizability and causal inference; however, convergent findings across stakeholder perspectives justify further investigation through controlled trials. Companion robots represent a feasible, low-burden adjunct to psychosocial care in pediatric settings.

KEYWORDS

social robot; companion robot; pediatric hospitalization; psychosocial intervention; LOVOT; child health; caregivers; health care staff

Introduction

Hospitalization represents a significant source of stress for children and their families. Children may experience anxiety, fear, and emotional distress due to unfamiliar environments, separation from home, painful procedures, and disruption of daily routines [1,2]. These negative experiences can impair recovery, increase behavioral problems, and produce lasting psychological effects [3]. Caregivers also experience substantial stress when their children are hospitalized, which can affect their own well-being and their ability to support their children [2,4].

Various interventions have been developed to address the psychosocial needs of hospitalized children. Play therapy and child life programs are well-established approaches that use play to reduce anxiety and facilitate coping [5-7]. Animal-assisted therapy has also shown promise in reducing stress and improving mood in pediatric settings [8,9]. However, animal-assisted therapy faces practical limitations including infection control concerns, animal welfare considerations, allergies, and inconsistent availability [10,11].

Social robots have emerged as a potential alternative or complement to existing interventions. These robots are designed to interact with humans in socially meaningful ways and have been studied in various health care contexts [12,13]. In pediatric settings, social robots such as Paro (a therapeutic seal robot) and humanoid robots have demonstrated positive effects on children's emotional states and engagement [14-17]. Social robots offer practical advantages over live animals, including consistent availability, no infection risk, and standardized interaction quality.

LOVOT is a companion robot developed in Japan that differs from most social robots studied in health care. Rather than performing tasks or engaging in verbal communication, LOVOT is designed exclusively for emotional engagement through nonverbal interaction, featuring warmth, softness, and an endearing appearance that encourages physical contact such as holding and stroking [18]. To date, no studies have examined LOVOT's effects in pediatric health care settings.

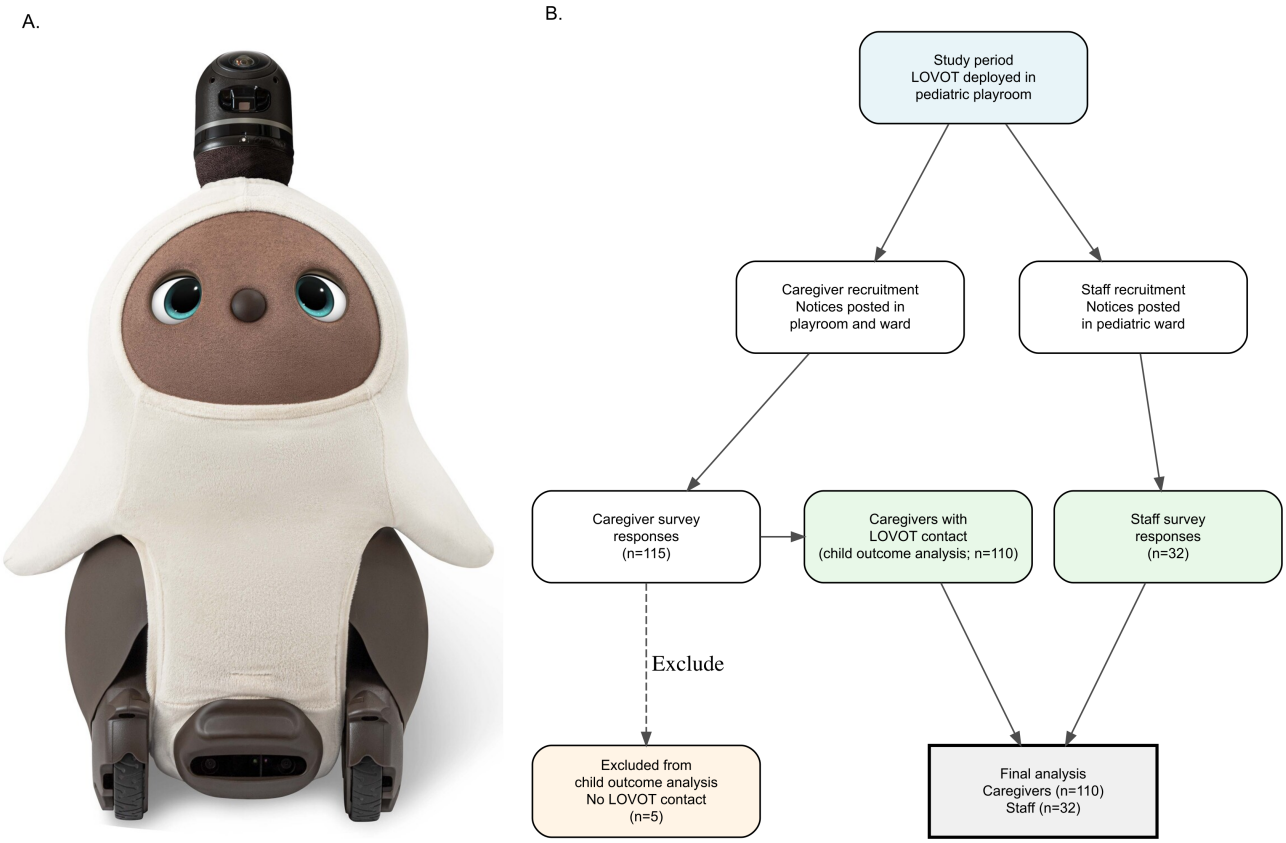
The aim of this study was to assess the perceived impact of LOVOT on hospitalized children, their caregivers, and health care staff in a pediatric ward. We examined perceived changes in psychosocial outcomes following LOVOT introduction using retrospective questionnaires administered to caregivers and staff complemented with qualitative analysis of free-text responses.

Methods

Study Design and Setting

This prospective observational study was conducted at the Department of Pediatrics, Hyogo Prefectural Amagasaki General Medical Center, Japan, between May 2024 and March 2025.

Participants



Caregivers of hospitalized children who used the pediatric playroom during the study period were eligible to participate. Questionnaires were available in the playroom for voluntary completion. Caregivers who answered "No" to the question asking whether they had any contact with LOVOT were excluded from analysis. Children's demographic and clinical characteristics were reported by their caregivers. During the study period, approximately 2500 children were admitted to the pediatric ward, of whom an estimated 25% used the playroom (approximately 625 children); however, the exact number of unique playroom users was not systematically recorded because no check-in system was in place. The estimated response rate was 18.4% (115/625), although both the numerator (respondents) and denominator (playroom users) involve uncertainty, and the true response rate may differ. All health care professionals working in the pediatric ward were invited to participate.

LOVOT Intervention

Two LOVOT 2.0 units (Groove X, Inc) were permanently installed in the pediatric playroom, enabling free interaction among hospitalized children, families, and health care staff throughout the study period (Figure 1A). LOVOT is designed for nonverbal communication through physical contact, featuring a warm body temperature (approximately 37 °C), a soft tactile exterior, and an endearing appearance that encourages holding and stroking (detailed technical specifications are provided in Multimedia Appendix 1).

XSL•FO
RenderX

Figure 1. Study overview: (A) LOVOT companion robot used in the study and (B) study flow diagram showing participant recruitment and exclusion criteria.

Health care staff received a brief orientation on LOVOT handling and basic maintenance (charging and cleaning); however, no structured intervention program or protocol was implemented. This approach was chosen to maintain naturalistic observation conditions and assess LOVOT's effects in real-world clinical practice. For infection control, LOVOT's removable clothing was changed and laundered every 2 to 3 days, and the surface was cleaned daily with alcohol-containing disinfectant wipes. LOVOT required approximately 15 minutes of charging per hour; during charging periods, children could still interact with LOVOT and often enjoyed observing it in a "sleeping" state.

Data Collection

Caregivers completed a self-administered postintroduction questionnaire with retrospective ratings of perceived change using 5-point Likert scales (1="much worse," 2="somewhat worse," 3="no change," 4="somewhat better," and 5="much better"). No baseline assessment was conducted prior to LOVOT introduction. A study-specific questionnaire was developed because no validated instrument existed for assessing the perceived impact of companion robots in pediatric settings. Existing measures of child distress or anxiety (eg, the Child Health Questionnaire) assess current states rather than perceived change attributable to a specific intervention, and general technology acceptance scales do not capture the psychosocial domains relevant to this study. Questionnaire items were drafted based on clinically relevant domains identified from the social robotics literature [12,13,19] and reviewed for content and face validity by the multidisciplinary research team, including pediatricians, nurses, and childcare workers. Internal consistency was assessed post hoc using the Cronbach α; however, formal psychometric validation, including test-retest reliability and construct validity, was not conducted. The questionnaire included 10 items assessing child outcomes (7 items) and caregiver outcomes (3 items), along with demographic information and free-text responses (Table S1 in Multimedia Appendix 2).

Staff completed a questionnaire using the same 5-point Likert scale, including 12 items assessing impact on children and caregivers (7 items) and impact on staff and ward environment (5 items), along with demographic information (Table S2 in Multimedia Appendix 2).

Statistical Analysis

All statistical analyses were conducted using R (version 4.5.1; R Foundation for Statistical Computing). Python (version 3.13.7; Python Software Foundation) was used for qualitative text analysis. All analysis code is publicly available [20] under the MIT License.

No primary outcome was prespecified; all analyses were exploratory. For quantitative data, 1-sample tests compared ratings against the baseline value (3="no change"), with normality assessed using the Shapiro-Wilk test. 2-tailed *t* tests were used for normally distributed data; Wilcoxon signed-rank tests were used for nonnormally distributed data. The Benjamini-Hochberg procedure controlled the false discovery rate (FDR; value of <.05). Effect sizes were calculated using the Cohen *d* from 1-sample tests (mean difference from baseline divided by sample SD), interpreted as small (0.2), medium (0.5), large (0.8), very large (1.2), and huge (≥2.0; [21]). Because

XSL•FO
RenderX

these 1-sample effect sizes compared ratings against a fixed neutral baseline rather than a control group mean, they were expected to be larger than between-group effect sizes from controlled designs and should not be directly compared to effect sizes from randomized controlled trials. Likert ratings were treated as interval data for this purpose; the resulting Cohen *d* values should be read as indexes of the magnitude of departure from the neutral midpoint, not as standardized between-group differences.

The internal consistency of the questionnaire subscales was assessed using the Cronbach α, calculated separately for child outcomes (7 items) and caregiver outcomes (3 items) on the caregiver questionnaire and impact on children and caregivers (7 items) and impact on staff and ward environment (4 items) on the staff questionnaire (workload was excluded from the latter subscale because it measures a conceptually distinct construct with a different scale direction).

Subgroup analyses stratified children's outcomes by age (≤5 vs ≥6 years), hospital stay duration (≤1 week vs >1 week), sex, and playroom use frequency. Caregiver and staff ratings were compared using Mann-Whitney *U* tests for 5 matched items. Missing data were handled on an item-by-item basis, with available responses analyzed for each variable.

For qualitative data, Japanese free-text responses were tokenized using the MeCab morphological analyzer with the fugashi library. A domain-specific stop word list (96 terms; Table S1 in Multimedia Appendix 3) was applied, and the top 20 high-frequency terms were visualized using horizontal bar charts, with Japanese-English translations provided in Table S2 in Multimedia Appendix 3. Emotion classification was performed using the LUKE-Japanese-large model fine-tuned on the WRIME dataset (a Japanese emotion corpus with multi-rater annotations), classifying responses into 8 emotions (joy, sadness, anticipation, surprise, anger, fear, disgust, and trust). Bootstrap 95% CIs were calculated with 5000 iterations.

Detailed statistical methods are provided in Multimedia Appendix 1.

Ethical Considerations

This study was conducted in accordance with the Declaration of Helsinki and approved by the Institutional Review Board of Hyogo Prefectural Amagasaki General Medical Center (approval number: 6-58). Informed consent was obtained from all participants through completion of a consent checkbox on the questionnaire, a method approved by the institutional review board given the anonymous, noninvasive nature of the survey. All data were collected anonymously; no personally identifiable information was recorded. Children's demographic and clinical characteristics were reported by their caregivers in aggregate form. Free-text responses were analyzed without any identifying information.

Results

Participant Characteristics

Of 115 caregiver respondents, 5 (4.3%) were excluded based on self-reported absence of LOVOT contact, resulting in a final analytical sample of 110 (95.7%) caregivers (Figure 1B). A total of 32 health care staff members completed the survey. Caregiver respondents were predominantly female (82/93, 88.2%), and the median child age was 5 (IQR 3-8) years. Staff comprised 45.2% (14/31) physicians, 48.4% (15/31) nurses, 6.5% (2/31) childcare workers; occupation was not reported by 1 staff member (Table 1). The children had hospital stay durations of 1 week or less (73/106, 68.9%), 1 week to 1 month (21/106, 19.8%), or 1 month or more (12/106, 11.3%). Most children used the playroom frequently (at least once per day: 66/105, 62.9%). Sex and age data were complete for all children (n=110); 48.2% (53/110) were male and 51.8% (57/110) were female. No adverse events related to LOVOT interaction, including injuries, falls, or choking hazards, were reported by caregivers or staff through spontaneous reporting during the study period, and no systematic adverse event monitoring protocol was implemented.

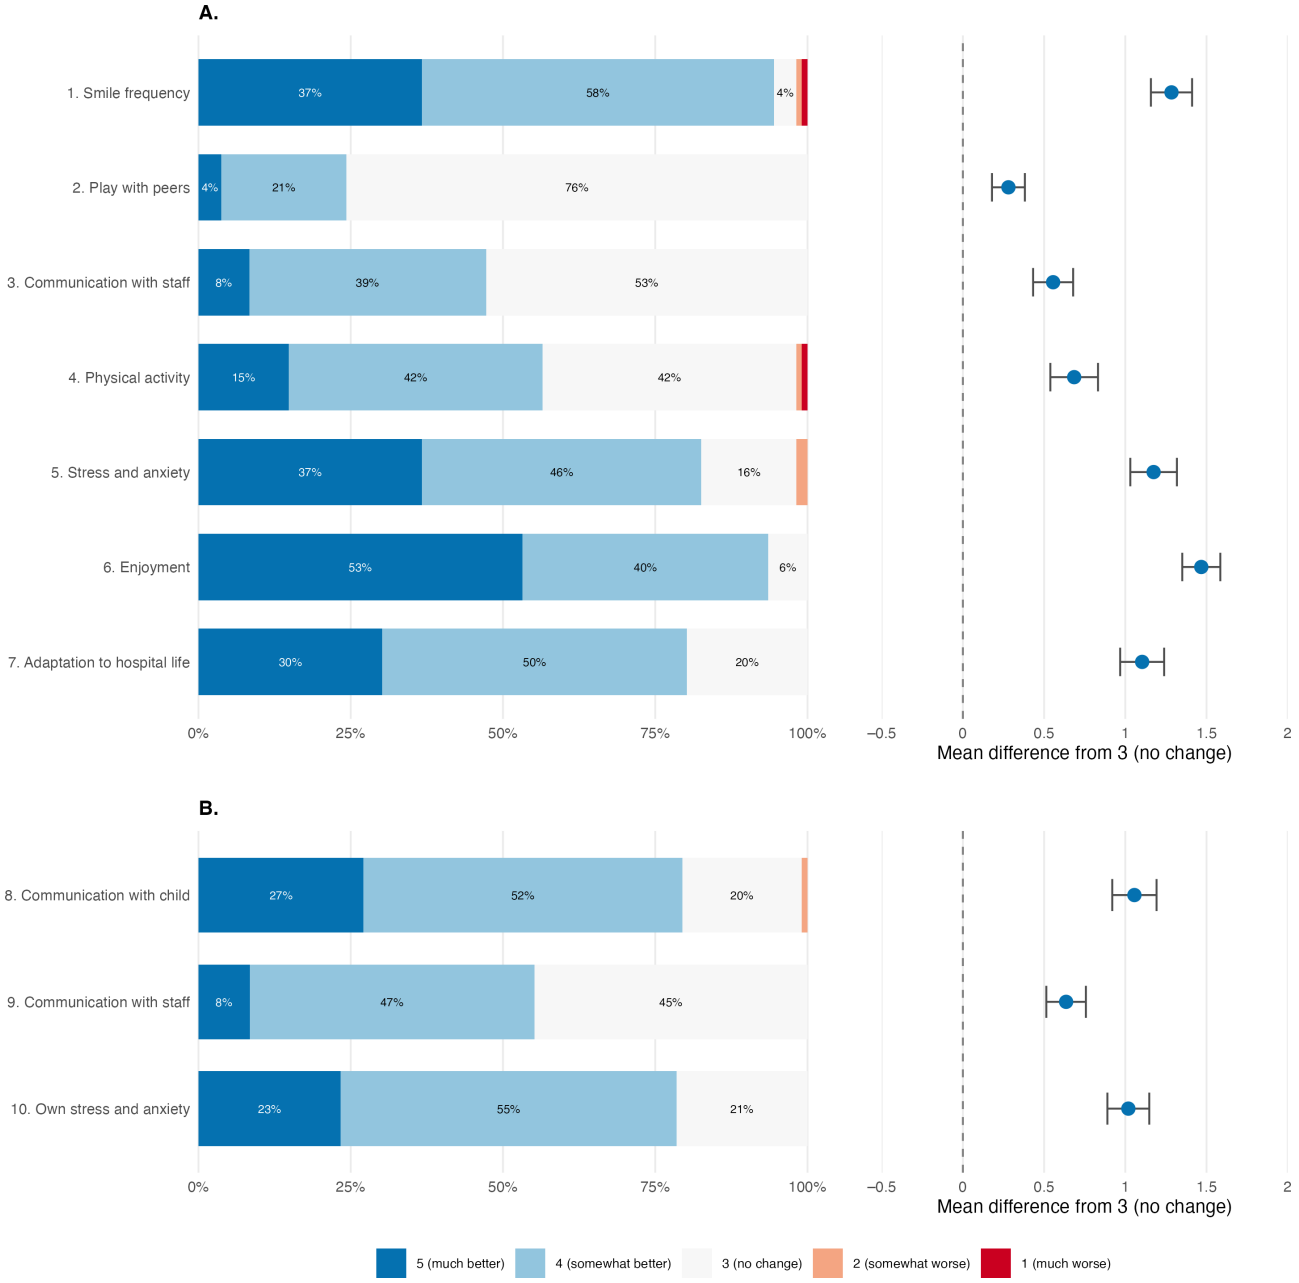
Questionnaire Internal Consistency



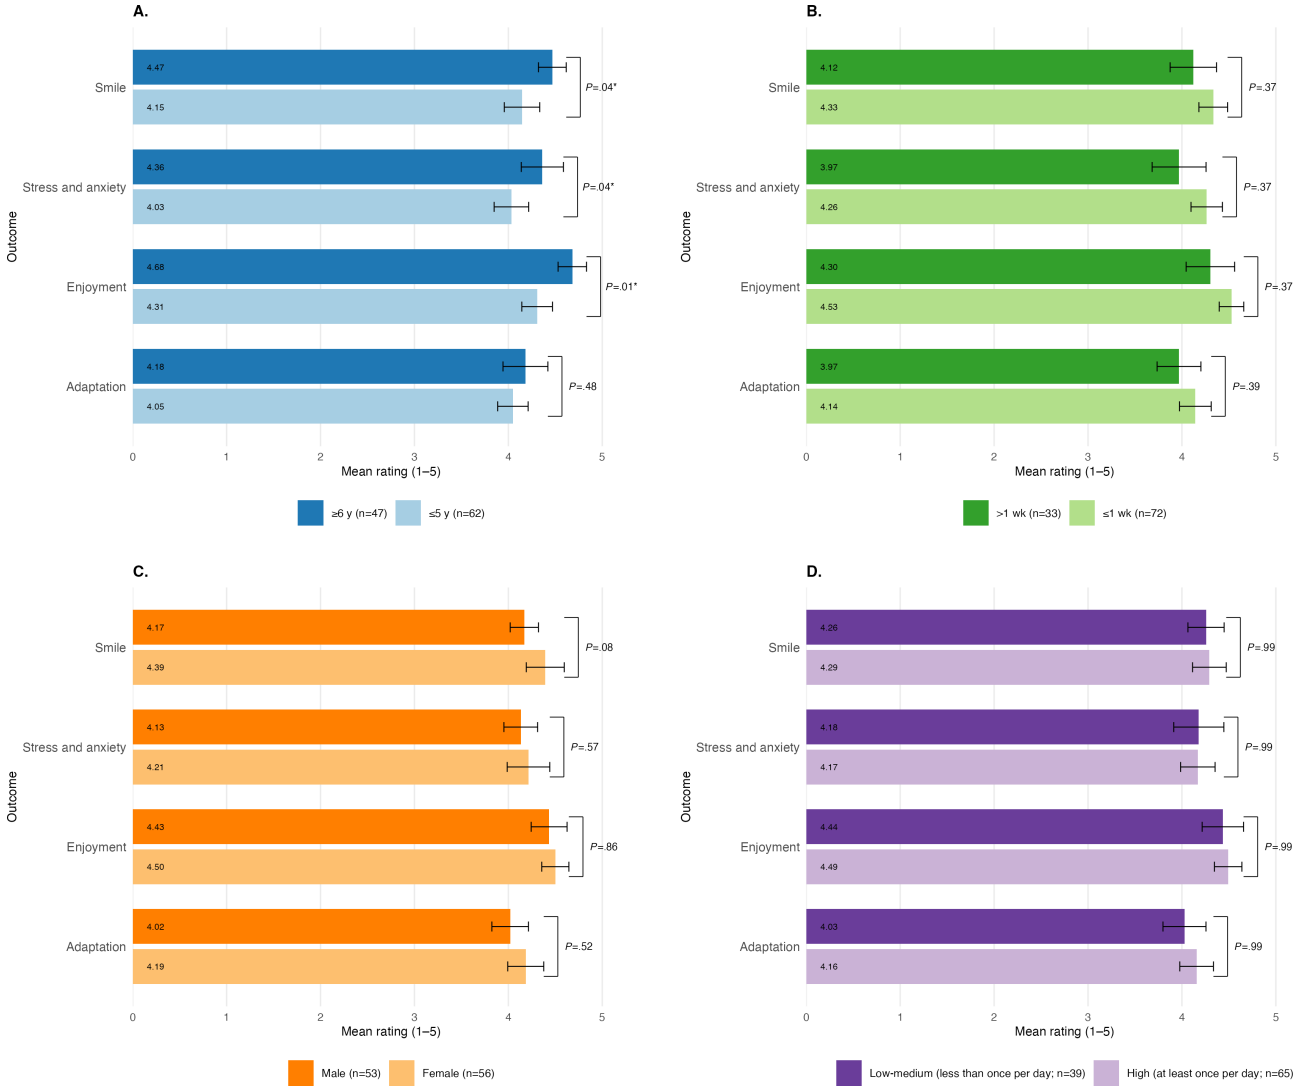
The Cronbach α values indicated acceptable to good internal consistency for the questionnaire subscales (child outcomes on the caregiver questionnaire [7 items]: Cronbach α=0.77; caregiver outcomes on the caregiver questionnaire [3 items]: Cronbach α=0.67; impact on children and caregivers on the staff questionnaire [7 items]: Cronbach α=0.84; impact on staff and ward environment on the staff questionnaire [4 items]: Cronbach α=0.77). The lower Cronbach α value for caregiver outcomes on the caregiver questionnaire reflects the small number of items (3 items); the mean interitem correlation for this subscale was 0.40 (SD 0.07), within the recommended range of 0.20 to 0.50.

Impact on Children and Caregivers

All 10 caregiver-rated items showed statistically significant perceived improvement after LOVOT introduction (P<.001 in all cases, FDR corrected; Figure 2; Table S1 in Multimedia Appendix 4). These ratings reflect caregivers' perceived change relative to the neutral midpoint (3=“no change”) and should be interpreted as perceived improvements rather than objectively measured effects. One-sample effect sizes (Cohen d) ranged from 0.53 to 2.38, indicating medium to very large effects by conventional benchmarks, although these 1-sample estimates should be interpreted cautiously as they are not directly comparable to between-group effect sizes from controlled trials. The largest perceived improvements were reported for children’s enjoyment of hospital life (d=2.38; mean 4.47, SD 0.62), stress and anxiety reduction (d=1.55; mean 4.17, SD 0.76), and adaptation to hospital life (d=1.57; mean 4.10, SD 0.70). Caregivers also reported reduced personal stress and anxiety (d=1.51; mean 4.02, SD 0.67). Detailed results for all items are provided in Table S1 in Multimedia Appendix 4.

XSL•FO
RenderX

Figure 2. Caregiver-reported outcomes following LOVOT introduction (n=110): (A) children outcomes (items 1-7) and (B) caregiver outcomes (items 8-10). Left panels show the distribution of Likert-scale responses (1-5). Right panels show mean differences from baseline (3="no change") with 95% CIs. All items showed statistically significant perceived improvement (false discovery rate *P*<.001). Statistical test results are shown in Table S1 in Multimedia Appendix 4.



Consistency Across Patient Characteristics

Subgroup analyses revealed consistent perceived improvements across all examined patient characteristics (Figure 3; Table S2 in Multimedia Appendix 4). All subgroups showed mean ratings of more than 3 (no change) with *P*<.001 for within-group comparisons (FDR corrected). Between-group comparisons showed no significant differences for most items across hospital stay duration (≤1 week vs >1 week), sex, and playroom use frequency (at least once per day vs less than once per day), indicating broad applicability. For age groups, older children (≥6 years) showed significantly higher ratings than younger children (≤5 years) for smile frequency (*P*=.04), stress and anxiety reduction (*P*=.04), and enjoyment (*P*=.01), suggesting that school-aged children may be particularly responsive to LOVOT interaction; however, both age groups showed significant improvements overall.

XSL•FO

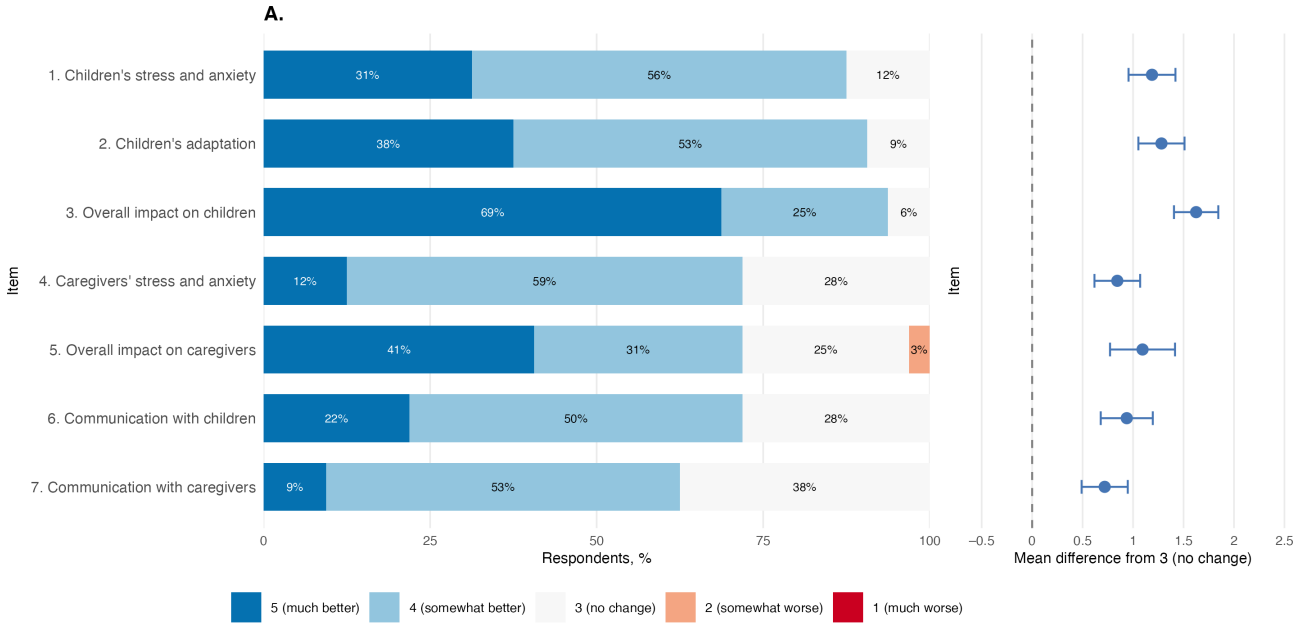
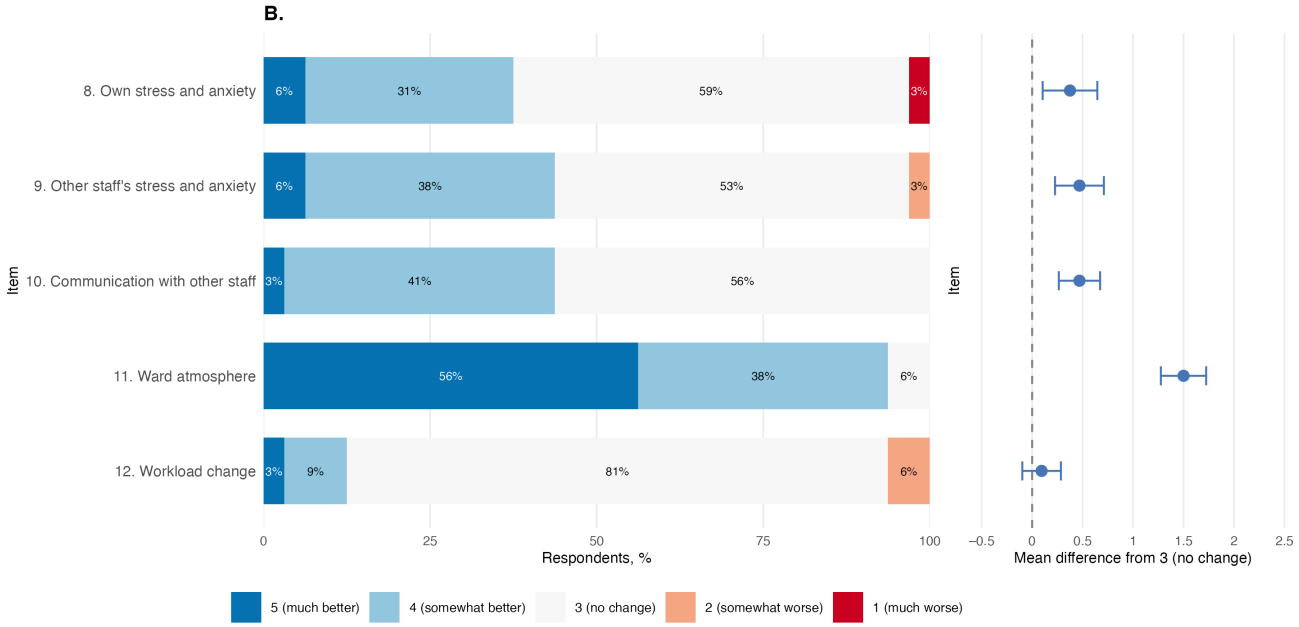
Figure 3. Subgroup analysis of children's outcomes. Comparison of effects across (A) age groups (≤5 vs ≥6 years), (B) hospital stay duration (≤1 week vs >1 week), (C) sex, and (D) playroom use frequency (at least once per day vs less than once per day). The bars represent mean ratings (scale from 1-5) with 95% CIs. Between-group comparisons were conducted using Mann-Whitney *U* tests with false discovery rate correction (see Table S2 in Multimedia Appendix 4 for complete results). *P<.05.



Health Care Staff Perspectives



Staff ratings demonstrated significant perceived improvements for 11 of 12 items (Figure 4; Table S3 in Multimedia Appendix 4). One-sample effect sizes ranged from 0.18 to 2.67. The largest perceived improvements were observed for overall impact on children (*d*=2.67; mean 4.62, SD 0.61), ward atmosphere (*d*=2.41; mean 4.50, SD 0.62), and children's adaptation (*d*=2.02; mean 4.28, SD 0.63). Staff also reported perceived improvements in children's stress and anxiety (*d*=1.84; mean 4.19, SD 0.64) and caregivers' stress and anxiety (*d*=1.34; mean 3.84, SD 0.63). Notably, no detectable increase in workload was observed (mean 3.09, SD 0.53; *d*=0.18; *P*=.37, FDR corrected), although the small sample size (n=32) limits statistical power to detect small to medium workload changes. Detailed results are provided in Table S3 in Multimedia Appendix 4.

Agreement Between Caregiver and Staff Ratings

For 5 matched items, ratings from caregivers and staff were compared using Mann-Whitney *U* tests with FDR correction (Figure 4). Four of 5 comparisons showed no significant differences: children's stress and anxiety (*P*=.92), children's adaptation (*P*=.36), caregivers' stress and anxiety (*P*=.36), and communication with caregivers (*P*=.61). Only communication with children showed a significant difference (*P*=.03), with staff rating perceived improvement higher than caregivers (mean 3.94, SD 0.72 vs mean 3.56, SD 0.65).

Qualitative Findings

Analysis of 91 free-text responses revealed predominantly positive experiences (Figure 5). The most frequent terms included "play" (n=46), "good" (n=25), "meet" (n=22), "enjoyment" (n=21), and "cute" (n=18), reflecting themes of play, positive evaluation, and emotional engagement. Emotion classification using the LUKE-Japanese-large model classified "joy" as the predominant emotion at both the document level (mean probability 88.7%, 95% CI 86.8%-90.6%) and sentence level (mean probability 72.3%, 95% CI 69.1%-75.5%). At the document level, most responses (82/91, 90.1%) were classified as joy dominant. Other emotions detected at lower probabilities included anticipation (6.8% at the document level and 14.8% at the sentence level) and fear (1.2% at the document level and 4.1% at the sentence level). The predominance of joy and the prominence of play and positive evaluation themes in the qualitative responses are consistent with the quantitative findings of perceived improvement in children's enjoyment and adaptation, and the 2 analyses thus reinforce each other.

Figure 5. Qualitative analysis of free-text responses (n=91): (A) top 20 high-frequency terms in the Japanese free-text responses, shown with their English translations (translation dictionary provided in Table S2 in Multimedia Appendix 3) and (B) emotion distribution comparing document-level (n=91) and sentence-level (n=271) classification using the LUKE-Japanese-large model. The bars represent mean emotion probabilities with 95% CIs (bootstrap: 5000 iterations).

Discussion

Principal Results

This study examined the perceived impact of LOVOT, a companion robot, on hospitalized children, their caregivers, and health care staff. Both caregivers and staff reported consistent perceived improvements across nearly all assessed outcomes, with mean ratings ranging from 3.28 to 4.62 on a 5-point scale. The largest perceived improvements were observed for children's enjoyment and overall well-being. However, because these effect sizes were calculated from 1-sample tests comparing retrospective ratings against a fixed neutral baseline (3="no change") rather than a control group, they are inherently larger than between-group effect sizes from controlled designs and should not be directly compared to those from randomized controlled trials. Importantly, no detectable increase in staff workload was observed, supporting implementation feasibility, although the small staff sample (n=32) limits power to detect small to medium workload changes. Accordingly, the nonsignificant workload result (P=.37) should be interpreted as the absence of a detectable increase rather than as evidence of no change and warrants confirmation in adequately powered studies. The convergence of findings across independent observer perspectives and predominantly positive qualitative responses strengthens confidence in these observations.

Comparison With Prior Work

The positive effects reported are consistent with the broader literature on social robots in health care settings. LOVOT, a companion robot designed for emotional engagement rather than task performance, shares characteristics with other social robots studied in pediatric care, such as Paro [14] and humanoid robots [15-17]. The 1-sample effect sizes in our study appear comparable to or larger than those previously reported [19]; however, direct comparison is limited by fundamental methodological differences as our 1-sample design yielded inherently larger effect sizes than the between-group designs used in most prior studies. Our findings also align with research on animal-assisted therapy, which has demonstrated reductions in anxiety and distress in hospitalized children [8,9]. However, animal-assisted therapy faces practical barriers in busy pediatric wards, including infection control concerns, the need for trained animal handlers, and inconsistent availability due to animal welfare requirements [10,11]. LOVOT offers practical advantages as a robotic alternative: it can be disinfected regularly, operates autonomously without requiring a handler, and provides 24-hour availability without rest periods. Its design, emphasizing passive, tactile interaction through warmth and softness rather than verbal communication, may be particularly suited to pediatric settings where children of varying ages interact freely.

Possible Mechanisms

Several mechanisms may account for these effects. Physical contact with soft, warm objects reduces stress through parasympathetic activation and oxytocin release [22,23]. The presence of tactile-related terms such as "hug" and "touch" in free-text responses supports the importance of physical contact. LOVOT may also function as a positive distraction, redirecting attention from medical concerns to enjoyable interaction [24,25]. Furthermore, LOVOT appears to serve as a social catalyst; staff reported improved communication with both children and caregivers, and "meet" was among the most frequent terms in qualitative responses. Some caregivers described attachment-like relationships developing, with temporal emotional transitions (initial fear→subsequent joy) suggesting LOVOT may facilitate adaptation to the hospital environment.

Implementation Feasibility

An important practical finding is that no detectable increase in staff workload was observed despite positive effects across other domains, addressing concerns about introducing new interventions in resource-constrained settings. This may be attributed to LOVOT's autonomous features, including automatic return to its charging station, which minimizes the need for staff intervention. The minimal training required and LOVOT's self-directed operation make it a low-burden intervention, distinguishing it from other therapeutic interventions that require dedicated staff time. Subgroup analyses revealed consistent effects across age, hospital stay duration, sex, and playroom use frequency, suggesting broad applicability. The substantial improvement in ward atmosphere indicates benefits extending beyond individual interactions. These findings support LOVOT as a feasible addition to pediatric care, complementing rather than replacing existing human-centered psychosocial support. For pediatric wards considering a similar deployment, our experience suggests that a shared playroom placement, a simple infection control routine (regular disinfection and laundering of removable clothing), brief staff orientation, and reliance on the device's autonomous operation are sufficient for day-to-day use. These observations are offered as preliminary practical guidance and require confirmation in controlled, multicenter evaluations.

Limitations

This study has several limitations. First, it relied on retrospective self-report measures of perceived change at a single postintroduction time point rather than prospective pretest-posttest assessments using validated clinical scales. No baseline data were collected prior to LOVOT introduction. Retrospective ratings are subject to recall bias, social desirability bias, and response shift bias (where participants' internal standards for evaluating change may shift over time), potentially inflating perceived improvements. Unlike a prospective pretest-posttest design, which captures contemporaneous baseline and follow-up measurements, our single–time point retrospective approach cannot separate perceived improvement attributable to LOVOT from natural recovery or adaptation occurring over the course of hospitalization. Thus, the reported improvements reflect caregivers' and staff's subjective perceptions rather than objective clinical changes. The observational design without a control group further limits causal inference as improvements may reflect natural adaptation or placebo effects, the stimulating playroom environment itself, or the novelty of interacting with a robot. Our design cannot disentangle these influences from any LOVOT-specific contribution. Additionally, no primary outcome was prespecified. Voluntary participation may have introduced

XSL•FO
RenderX

selection bias at multiple levels: caregivers who had positive experiences with LOVOT may have been more motivated to complete the questionnaire, and because questionnaires were available in the playroom, respondents were inherently those who used the playroom—creating a compound engagement bias favoring families with greater LOVOT exposure. Consistent with this, 62.9% (66/105) of respondents reported using the playroom at least once daily, which may overrepresent high-exposure families. The estimated response rate was 18.4% (115/625); however, the denominator was itself estimated based on the assumption that 25% of admitted children used the playroom, and the actual number of unique playroom users was not systematically recorded. This low and uncertain response rate means that findings may not represent the experiences of all playroom users and likely overestimate the perceived benefits of LOVOT. The staff sample (n=32) was relatively small, and the single-center design in Japan limits generalizability to other cultural contexts. Notably, Japanese culture has historically demonstrated a high affinity for robots, which may have positively influenced not only acceptance and willingness to interact but also the magnitude of perceived emotional benefits; whether similar effects would be observed in cultures with different attitudes toward robots remains to be determined. In regions where attitudes toward social robots are more skeptical, both acceptance and the magnitude of perceived psychosocial benefit may be attenuated; cross-cultural, multicenter replication is therefore needed before these findings can be generalized internationally. The study-specific questionnaires showed acceptable to good internal consistency (Cronbach α=0.67-0.84); however, formal psychometric validation including test-retest reliability and construct validity was not conducted. Without established construct validity, the extent to which items accurately capture the intended constructs remains uncertain, and the questionnaire items were designed to assess distinct facets of LOVOT's impact rather than a single unidimensional construct. The emotion classification model (LUKE-Japanese-large) was fine-tuned on general Japanese text rather than medical or pediatric contexts, and its validity for analyzing health care–related free-text responses has not been established. Because the model was trained on social media–style text, domain shift relative to caregivers' and staff's clinical free-text responses may bias the estimated emotion probabilities; we therefore treat the emotion classification results as exploratory and corroborative rather than confirmatory. The convergence between model-based classification and the model-independent high-frequency term analysis provides partial triangulation. We could not link the perceived outcomes to objective measures of interaction intensity: the device's internal interaction logs (eg, touch and hold frequency) were not available for research export under our deployment configuration, and no separate behavioral observation log was maintained. Integrating objective sensor- and behavior-derived metrics (touch frequency, hold duration, proximity, and interaction duration) is an important direction for future controlled studies and would strengthen the link between interaction and perceived benefit. Finally, the observation period (approximately 11 months) may not fully capture novelty effects or long-term sustainability, although subgroup analyses showed consistent effects among children hospitalized for longer periods (>1 week), suggesting that benefits may persist beyond initial novelty. Future studies should use randomized controlled designs with objective outcome measures, include longitudinal follow-up, and involve multiple centers across diverse cultural contexts.

Conclusions

This study provides preliminary evidence that LOVOT may positively affect hospitalized children, caregivers, and staff across multiple psychosocial outcomes. The convergence of findings across multiple stakeholder perspectives and analytical methods strengthens confidence in these observations, and positive effects were achieved without a detectable increase in staff workload. While the observational design and low response rate limit causal conclusions and generalizability, these findings justify further investigation through controlled trials with prospective outcome measures. Companion robots represent a promising adjunct to psychosocial care in pediatric settings.

Acknowledgments

The authors thank all participating families, children, and health care staff for their cooperation in this study. Generative artificial intelligence (AI) tools were used in the preparation of this manuscript. Claude Code (Anthropic) was used to assist in writing and debugging the R and Python scripts for statistical analysis and figure generation. In addition, AI-based tools were used for English-language editing and proofreading of the manuscript text. The authors reviewed and verified all AI-assisted output, made all scientific and interpretive decisions themselves, and take full responsibility for the content of the manuscript. Generative AI was not used to generate study data, interpret results, or author substantive scientific content.

Funding

This study was supported by departmental research funds from the Department of Pediatrics, Hyogo Prefectural Amagasaki General Medical Center. The LOVOT units were purchased using funds from the 2nd Sustainable Development Goals Japan Scholarship Iwasa Award (Medical Category, 2023), awarded to the Department of Pediatric Emergency Medicine at our institution. The LOVOT manufacturer (Groove X, Inc.) had no involvement in the study design; data collection, analysis, and interpretation; or manuscript preparation.

Abstract

Background: Based on its nature, cyberbullying is expected to be frequent and prevalent because of the continuity of technological advancement over time. This change results in more victims and is challenging to detect, negatively affecting their health. Given that adolescents in Jordan face a high rate of cyberbullying, it is essential to understand how this experience affects them.

Objective: This study aims to explore individual experiences and perspectives on cyberbullying victimization among adolescents to intervene and reduce future incidences of cyberbullying.

Methods: We based our analysis on a cross-sectional study investigating cyberbullying and its mental health consequences among 400 students aged 14-17 years from public schools in central and northern Jordan. These respondents were asked to answer 3 open-ended questions describing their experiences with cyberbullying if they experienced cybervictimization as either victims or bully-victims, resulting in 240 responses. Thematic analysis was then used to interpret patterns of shared meaning across participants' narratives related to cyberbullying experiences in cyberspace.

Results: A total of 3 key themes and several subthemes emerged from this study: (1) effects of cyberbullying, (2) challenges in overcoming its consequences, and (3) elements influencing the severity of cyberbullying experiences.

Conclusions: The findings offer valuable insights for creating safer online environments and reducing cyberbullying's psychological and social harms through appropriate interventions.

Introduction

Cyberbullying is defined as the intentional and repeated use of information and communication technologies to harm, harass, or humiliate others [1]. While the concept of bullying itself has long been studied, the rise of information and communication technologies has shifted many aggressive behaviors into digital spaces. The foundational work of Olweus [2] on traditional bullying remains relevant; however, cyberbullying differs significantly because of its anonymity, potential for wide audience reach, and persistence [3,4].

Adolescents are particularly vulnerable to cyberbullying due to their developmental stage, marked by rapid emotional, social, and cognitive changes [5,6]. According to Bronfenbrenner's Ecological Systems Theory, adolescents interact with multiple individual, family, peer group, and environmental factors that can all influence their experiences with cyberbullying [7]. As they form their identities and social competencies, they become more susceptible to peer pressure, social comparison, and emotional distress, increasing the risk of being both victims and perpetrators of cyber aggression [8,9]. Within this context, other findings suggest that extended online engagement, particularly during nonschool hours, combined with the use of anonymous or fake profiles, significantly increases the risk of cyberbullying [10]. The anonymity afforded by fake identities appears to lower social accountability and facilitate harmful behaviors, positioning such profiles as key risk factors in the digital ecology of adolescent cyberbullying [10].

Globally, cyberbullying prevalence varies depending on age group, data collection methods, and cultural context. In the United States, studies report adolescent victimization rates ranging from 3% to 72% and perpetration rates ranging from 1% to 41% [11]. Another national American sample of 1034 preadolescents aged 9-12 years completed an online survey to report their experience with cyberbullying. Of them, 21% have been exposed to cyberbullying as a target, aggressor, or witness to cyberbullying [12]. In Malaysia, 31.6% of adolescents reported recent victimization, and 20.9% reported perpetration [13]. In Indonesia, approximately 80% of seventh-grade students reported experiencing occasional cyber victimization [14]. In Saudi Arabia, the rate was 42.8%, with boys more affected than girls [15]. In Jordan, few studies exist, but moderate to high prevalence has been reported, often linked to educational level and academic performance [16-18]. These findings suggest that cyberbullying is a widespread issue, but one that requires culturally contextualized understanding.

Cyberbullying has serious psychological consequences, particularly for adolescents. Victims often experience anxiety, depression, low self-esteem, and social withdrawal [19,20]. Cyberbullying differs from traditional bullying in its ability to invade the victim's private space continuously, and the anonymity of aggressors intensifies its effects [4]. The diathesis-stress model of psychopathology posits that psychological problems arise from a combination of an individual's experience of stressful events and their inherent susceptibility to developing the disorder [21]. This model helps explain how individual vulnerabilities (eg, impulsivity and low self-regulatory efficacy) interact with environmental stressors such as cyberbullying to produce mental health symptoms [22]. Limited coping skills, a lack of social support, and the ubiquity of digital access can exacerbate the impact [3].

Despite growing research on cyberbullying, many studies focus on prevalence and institutional responses, often overlooking the subjective experiences of adolescent victims. A deeper comprehension of the context of bullying and its effects on young people is required [23]. There remains a critical gap in understanding how victims personally experience and cope with cyberbullying, as well as the long-term psychological, emotional, and social repercussions of this type of behavior. This gap is particularly critical in regions such as the Middle East, where digital behaviors intersect with unique social and cultural norms [24]. In Jordan, youth face distinct challenges related to family expectations, gender norms, and limited digital literacy resources [25,26]. These factors may shape how cyberbullying is perceived, reported, and addressed. Understanding adolescents' lived experiences in this context is essential for developing effective, culturally grounded interventions. Since cyberbullying can be prevented through several interventions and programs [27], current interventions might not be deep enough to address victims' particular struggles if victims' voices are not included, which could result in an insufficient support network.

Therefore, this study aims to explore the lived experiences of Jordanian adolescents who have been victims of cyberbullying, focusing on their emotional reactions, coping mechanisms, and self-perceptions. This victim-centered approach is grounded in the principles of trauma-informed care, which emphasizes safety, empowerment, and recognition of the long-term psychological impact of trauma, especially in adolescent populations [28,29]. By centering adolescents' narratives, the study aligns with narrative psychology, which recognizes the role of personal storytelling in shaping identity, meaning-making [30], psychological growth, and event distress [31]. Furthermore, this perspective reflects the principles of participatory and context-sensitive research, which advocate for involving participants as active contributors to knowledge production and ensuring interventions are culturally and socially relevant [32]. In doing so, the study addresses a critical gap in the literature and contributes valuable insights for the design of culturally grounded, psychologically responsive cyberbullying interventions in the Jordanian context.

Since this study is likely grounded in exploratory and descriptive goals rather than hypothesis testing, several exploratory questions were provided to align with the narrative and qualitative nature of the study, as follows:

- How do adolescents who have experienced cyberbullying describe its effects?
- What factors do adolescents who have experienced cyberbullying perceive as worsening the impact of cyberbullying on their well-being?
- What ongoing challenges to recovery from cyberbullying do adolescents who have experienced cyberbullying report?

Methods

Ethical Considerations

Institutional Review Board approval was obtained first from the University of Wisconsin-Milwaukee (#24.112), followed by approval from the Jordan Ministry of Education (#4218) and school principals. Participants were informed of their right to withdraw at any time without consequences and of the confidentiality of their data. Parental consent and student assent were secured before data collection. The procedures used in this study adhere to the tenets of the Declaration of Helsinki.

Design and Setting

This is a qualitative descriptive study embedded within a cross-sectional survey aimed at examining the prevalence of cyberbullying and investigating its mental health impacts among adolescents and whether gender may moderate the correlation between cyberbullying and mental health. The current qualitative analysis was not explicitly designed to investigate gender differences in narrative content. The main objective was to investigate common experiences and significant themes concerning the effects of cyberbullying on adolescents instead of performing a comparison among demographic subgroups. Using a qualitative descriptive approach provides a practical method for revealing the facts of a phenomenon without requiring an in-depth focus on meaning, as in other qualitative methods such as phenomenology, especially among adolescents [33]. A total of 8 governmental schools in central and northern Jordan were selected for their accessibility and the availability of teachers to facilitate data collection. These schools accommodate a large student population due to mandatory primary education laws [34], with Amman and Irbid, the most populous cities, facilitating recruitment.

Participants, Sample, and Instrument

Participants were male and female adolescents aged 14-17 years in grades 9-11 from public schools in central and northern Jordan. A multistage stratified cluster sampling method was used to select geographical areas, education directorates, schools, and classes. Students diagnosed with uncontrolled mental illness, intellectual disabilities, or narcotic drug use were excluded because of potential impacts on mental health and cyberbullying involvement. School representatives (eg, school principals or teachers) were asked whether students in the selected classes had any detected exclusion conditions that needed to be addressed to ensure the exclusion criteria were met. Also, the exclusionary conditions (chronic illness and untreated psychological disorder) were explained in the consent form so that participants or guardians could decide. Accordingly, no one was excluded.

A total of 400 participants completed a survey consisting of several sections. Participants' involvement in cyberbullying was assessed using the Revised Cyber Bullying Inventory–II (RCBI-II) Questionnaire [35], which includes 10 statements presented in 2 parallel columns, and participants must respond from the viewpoints of both the bully and the victim in the last 6 months. Each item is rated on a 4-point Likert scale reflecting the frequency of behaviors. Based on participants' scores, individuals were categorized into involvement groups. A "bully-victim" was operationally defined as a participant who scored >10 points in both the cyberbullying and cybervictimization sections. In contrast, "pure victims" were those who scored >10 points on cybervictimization only without endorsing any perpetration behaviors, whereas "pure perpetrators" reported perpetration only (scored >10 points on the cyberbullying section). This classification approach is consistent with prior studies using the RCBI-II, allowing differentiation among distinct roles in cyberbullying involvement.

The last section of the survey asked participants to complete it only if they had experienced victimization. As a result, 240 participants (identified as victims or bully-victims based on the RCBI-II) answered 3 additional questions narratively about their online victimization to understand the impact of cyberbullying on them. Those questions were as follows: "What was the effect of the cyberbullying involvement you have had?" "What do you think makes the effect of experiencing cyberbullying worse on you?" and "What are the factors that determine the severity of cyberbullying impacts?" Each of these questions was intended to answer the previously provided research questions. Open-ended survey responses were selected for their ability to enable participants to convey personal experiences in a flexible, anonymous, comfortable, and less intrusive way compared with semistructured interviews or focus groups, which was especially fitting given the sensitive nature of the subject and the adolescent study group. This approach also allowed the inclusion of diverse, large samples within the limits of time, resources, and accessibility, which might not have been practical with interviews or focus groups.

Procedure

Data were collected between January and February 2024. Students were briefed on the study's purpose, procedures, voluntary participation, confidentiality, and withdrawal rights during the first interview. Parental consent and student assent were secured before data collection. Consent forms were distributed during parent-teacher conferences and sent home for signature. School representatives (eg, school principals or teachers) were asked to send the recruitment flyer to parents who did not attend the conferences, reach out to them, explain the study's purpose and procedures, and send the consent forms. Data were collected individually using paper-and-pencil questionnaires in private rooms by researchers and assistants administering the questionnaires, taking 30-40 minutes per student. Personal incentives were provided upon completion, but they were simple, such as pens and notebooks, to avoid any bias in participation or responses. Consent forms and questionnaires were entered into Qualtrics via University of Wisconsin-Milwaukee access. At the same time, hard copies were kept anonymous and securely stored in a locked file cabinet in the researcher's office in Jordan.

When using mental health, behavioral, and quality-of-life assessments, the Committee on the Use of Humans as Experimental Subjects evaluates the merits and drawbacks of addressing these topics with study participants [36]. It assists researchers in determining whether to include mental

XSL•FO
RenderX

health-related inquiries and devising risk mitigation plans. Unintentional identification may occur when assessing quality-of-life issues like sadness, anxiety, or stress, prompting the Committee on the Use of Humans as Experimental Subjects to recommend a "safety plan" for populations at elevated risk [36]. This plan involved assessing the immediacy of risk by qualified researchers on "Social and Behavioral Research Best Practices for Clinical Research," providing staff training on intervention procedures, and offering participants a resource referral flyer because the data would be anonymous; the flyer included mental health resources, crisis intervention services, or hotline information, depending on the type of risk. After completing data collection, none of the participants required intervention under this protocol.

Data Analysis

Overview of the Analytic Process

Descriptive statistics, including means, SDs, percentages, and frequencies, were used to describe participants' demographic characteristics. Then, a thematic analysis strategy was used as a structured and flexible framework to detect, analyze, and interpret patterns of shared meaning across participants' narratives of cyberbullying experiences in cyberspace [37]. Braun and Clarke's [38] 6-phase framework for thematic analysis was specifically used to analyze the data and is one of the most clearly defined approaches to performing reflexive thematic analysis to describe and summarize data and to offer a range of higher-level inductive or deductive analyses of small or large datasets [39]. The phases are familiarization, coding, initial theme generation, theme development and review, theme definition and naming, and writing up [38]. This framework was suited to this study's aim of exploring the lived experiences of Jordanian adolescents who have been victims of cyberbullying, concentrating on their emotional reactions, coping mechanisms, and self-perceptions. The application of each phase is described in the following subsections.

Phase 1: Familiarization With the Data

This stage involves examining and reexamining data to gain a deeper understanding of the specifics and the broader context of the data, typically beginning with an emphasis on the more evident semantic interpretations before progressing to an analytical engagement with the data [38]. Applying this, participants' responses were translated from Arabic to English using a forward-backward strategy by 2 bilingual translators proficient in both English and Arabic, with knowledge of health care and qualitative research terminology. The first translator translated the Arabic responses into English. The translator and research team discussed and compared the translated versions to create a unified, agreed-upon English version.

Then, backward translation into Arabic was conducted by a second translator who was blinded to the original Arabic version to ensure accuracy and evaluate language clarity. The back-translated versions were compared with the initial responses to detect inconsistencies, ambiguities, or loss of significance. Careful emphasis was placed on maintaining the semantic, cultural, and contextual significance of terms associated with cyberbullying experiences in the Jordanian sociocultural framework. The first author read and reread the transcripts to gain an in-depth understanding of the participants' accounts while noting preliminary impressions and recurrent expressions related to emotional reactions, coping strategies, and perceptions of online interactions.

Phase 2: Coding

This phase starts by organizing data systematically and meaningfully, reducing large amounts into smaller, more meaningful segments. Coding methods can vary, but one approach is to address the research question, which yields theoretical rather than inductive analysis. Thereby, following open coding, which means that we do not have preset codes but rather a coding process [40], we assigned codes to every segment of data that pertained to or highlighted something significant regarding our research question. To enhance engagement with participants' responses, the original coding was carried out manually by the first author, who identified meaningful text units, essential elements, related phrases, and patterns that reflected the research aim, condensed them, arranged them according to similarities and differences, and lastly assigned codes that possess characteristics such as "anxiety and fear," "stress and pressure," and "social agreement."

A selection of the transcripts was independently reviewed by the senior author, who also provided interpretive comments on the coding scheme and thematic organization to ensure reliability. Through cooperative interpretation and consensus building, investigator triangulation was used to reinforce trustworthiness, even though formal intercoder reliability metrics were not computed. Two authors reviewed transcripts and coded data independently to minimize individual interpretive bias. Inconsistencies in coding and theme understanding were addressed through ongoing discussions and agreement. To enhance analytical rigor and minimize possible coder bias, reflexive memoing and peer debriefing were also used to record researchers' beliefs, analytical choices, and thoughts regarding possible impacts on data interpretation. The researchers were mindful of how their expertise and prior knowledge of cyberbullying research might influence their interpretations; therefore, they engaged in ongoing critical reflection throughout coding and theme development. Emphasis was placed on reducing power dynamics by highlighting voluntary participation, ensuring confidentiality, and allowing participants to skip questions or withdraw at any time.

Phase 3: Search for Themes

A theme is a manner that reveals something meaningful or intriguing concerning the data and/or research inquiry [40]. To align with that, the codes were checked for conceptual uniformity and grouped into candidate themes developed by observing recurring patterns in the data. For instance, following connected codes "anxiety and fear," "stress and pressure," and "emotional distress" were assorted into the psychological effects of cyberbullying theme. While codes reflecting "facing the uncomfortable," "disconnection," and "invisible perpetrators" formed a theme called challenges in overcoming cyberbullying consequences. Thematic analysis was conducted iteratively, and codes were contrasted across responses until no new themes emerged, showing a degree of thematic adequacy suitable for

XSL•FO
RenderX

this research design. Despite the responses being relatively brief, the substantial sample size (n=240) provided a wide range of viewpoints, enabling the identification of consistent trends and prevalent themes.

Phase 4: Reviewing Themes

The identified themes were then reviewed to enhance clarity and coherence. Some overlapping codes were merged, and all themes were checked against the data to verify their reflection of a deeper understanding of participants' viewpoints and experiences with cyberbullying. When suitable, subthemes were created to encapsulate detailed yet consistent patterns of significance within overarching themes. Subthemes were used purposefully to deepen analysis and were not regarded as hierarchical classifications or subcategories. This iterative process enhanced the validity and clarity of the thematic structure.

Phase 5: Defining and Naming Themes

The final thematic structure included 3 major themes: effects of experiencing and being involved in cyberbullying (psychological and social effects), challenges in overcoming consequences of cyberbullying experiences (anonymity of perpetrators, threat and exposure context, and public exposure of incidents), and elements influencing the severity of cyberbullying experiences (individual vulnerability, social response, and digital environment). All themes and subthemes were explicitly outlined to highlight a unique facet of adolescents' experiences of cyberbullying in digital environments, focusing on the interaction between emotional distress, social relationships, and situational influences. During this process, analytic choices were influenced by a focus on meaning-based interpretation rather than frequency or classification.

Phase 6: Producing the Report

In the final phase, the results were presented using themes and subthemes, which were synthesized into a coherent narrative supported by illustrative verbatim quotations that reflected the variation and depth of experiences, in parallel with Braun and Clarke's [38] reflexive thematic analysis. This framework provides a rich understanding of the psychological, social, and technological aspects of cyberbullying as experienced by adolescents. The findings were interpreted within the framework of adolescent developmental psychology and the sociocultural context of Jordan.

Results

Descriptive Characteristics of the Participants

A total of 240 participants admitted to engaging in cyberbullying as a victim or bully-victim; of these, 47% (113/240) were females aged 14-17 years, with a mean age of 15.2 (SD 1.01) years. Approximately half were located in Amman. The distribution of grades was approximately 34.2% (82/240) in 9th grade, 32.8% (79/240) in 10th grade, and 33% (79/240) in 11th grade. Approximately 34.8% (83/240) of participants were unaware of their monthly earnings; 30% (72/240) indicated earning between JD 500-1000 (Jordanian dinars; exchange rate: JD 1=US $0.70 as of February 4, 2024), 29% (70/240) earned less than JD 500, and 6.3% (15/240) earned more than JD 1000. Concerning academic achievement, 27% (65/240) indicated an average above 90 in the previous semester, 25.8% (62/240) averaged between 80 and 89, 23% (55/240) between 70 and 79, 13.7% (33/240) between 60 and 69, and 10.5% (25/240) below 60.

All participants had internet access, and 81.5% (196/240) reported having 1-5 social media accounts, with about 64.7% (155/240) spending 1-7 hours online daily. About 51.4% (123/240) of the people who engaged in cyberbullying were victims, and 48.6% (117/240) were bully-victims. Answers to the questions assessing the bully's identity indicated that 47.1% (113/240) of the 240 people who reported being a victim, a bully, or a bully-victim had met a bully in real life, and 44.2% (106/240) said the bully was the same gender as them. Friending the bully was the most common relationship (99/240, 41%), followed by someone in the school (46/240, 19.2%), strangers (42/240, 17.5%), former friends 29/240, 12.1%), and chat room users (24/240, 10%), respectively. Three key themes and 8 subthemes emerged from this study: (1) effects of experiencing and being involved in cyberbullying, (2) challenges in overcoming consequences of cyberbullying experiences, and (3) elements influencing the severity of cyberbullying experiences (Table 1).

Table 1. Themes and subthemes related to cyberbullying experiences.

Theme	Subthemes
Effects of experiencing and being involved in cyberbullying	• Psychological effects (eg, anxiety, emotional distress, and sleep disturbances) • Social effects (eg, isolation, withdrawal, and relationship difficulties)
Challenges in overcoming consequences of cyberbullying experiences	• Anonymity and sense of powerlessness (difficulty identifying perpetrators and lack of control) • Threatening and exploitative nature (fear, coercion, and misuse of personal content) • Public exposure and wider harm (rapid dissemination and long-term reputational impact)
Elements influencing the severity of cyberbullying experiences	• Individual vulnerability and coping capacity (age, resilience, prior experiences, and self-confidence) • Role of others in shaping the experience (peer, family, and institutional responses) • Digital environment as an enabler (cyberbullying tactics, the purpose of cyberbullying, the number of bullies, the lack of regulations and penalties, and platform features that facilitate the spread of harmful content)

XSL•FO
RenderX

Themes

Effects of Experiencing and Being Involved in Cyberbullying

Psychological Effects

Participants stated profound emotional consequences of being involved in cyberbullying as victims or bully-victims. Feelings of badness, leading to crying because they did not know how to deal with such an experience, were common. Further, feelings of emotional distress, anxiety, fear, stress, and pressure, and cognitive and behavioral issues were recurrently expressed. The following quotes illustrate those feelings. For anxiety and fear, a participant said, "I felt embarrassment, inferiority, ugliness, dissatisfaction with one's body, and a feeling of not being included with other people in society." While this quote, "I got angry and sensitive regarding any word," is an example of stress and pressure. Finally, the following quote reflects cognitive and behavioral issues:

> *I felt unfortunate; I felt that I do not deserve friends, I do not trust anyone, even my friends, I have suicidal ideation because the people around me damage my heart.*

Several participants reported intrusive thoughts, sleep disturbances, and a sense of helplessness. One participant noted:

> *I felt afraid to open my phone because I did not know what I would find next... I was thinking about that the whole night, so I was not able to sleep.*

Some mentioned self-accusation and internalized shame, thinking they had somehow triggered or warranted the bullying. Such responses frequently resulted in diminished self-esteem and a negative self-image, as one participant explained: "I started to think, is there something wrong with me?!" Another participant stated, "I had bad feelings because I did not know how to deal with that person and get revenge on him... I felt like a useless and bad person in this life."

Social Effects

Participants reported experiencing equally significant social effects. Many participants reported altered trust in others, becoming more cautious, withdrawing from social circles, and experiencing isolation and loneliness, along with changes in social situations, as a result of their experiences.

> *I remember when I posted strictly in the snap in a group, then a girl bullied me and said I am a Lier, black, and ugly; I left the group and broke the phone.*

Another participant stated:

> *It is a bad experience to the degree that you do not want to confront others and felt embarrassment, making you isolated and do not want to see others.*

Participants described being isolated from others because of feeling forsaken and depressed, which subsequently affected their academic performance, social interaction, and caused social anxiety and loneliness, especially if the perpetrator is a close person. Others described avoiding social interactions in schools or online platforms to avoid victimization. A participant described:

> *The experience impacted my social relationships directly... it affects social situation by being isolated from others and affects academic performance.*

Another one said, "I stopped talking to my peers because I thought they were all laughing at me." These experiences often damaged friendships and family relationships, intensifying feelings of loneliness and social alienation.

Challenges in Overcoming Consequences of Cyberbullying Experiences

Overview

This theme highlights several traits that make the cyberbullying experience terrible and hinder participants' ability to recover from cyberbullying victimization, including knowing the identity of the perpetrator, the exploitative nature of cyberbullying, and public exposure.

The Anonymity and Sense of Powerlessness

The participants addressed this subtheme by mentioning 3 features that intensify the difficulty of coping with harm caused by a hidden perpetrator: a disconnected, invisible perpetrator, and facing the unconfrontable. The anonymity of the perpetrator is the most reported trait because the inability to see the perpetrator is a provocative thing, not to know who is behind the screen, so they say whatever they want without fear, freely, and make it difficult to confront them, subsequently, making it difficult to limit or control cyberbullying, especially through the distancing communication, which amplified feelings of powerlessness and fear. As one participant expressed, "not knowing who was behind the screen made me feel fear and unsafe everywhere."

The following quote refers to facing the unconfrontable feature:

> *The anonymous feature of the perpetrator is terrible, so you cannot reach the perpetrator to confront and defend yourself and talk about your feelings.*

The bullies cannot see the victim, then will say whatever they want without fear, freely, which represents the invisible perpetrator feature. The following quote is an example of the disconnected feature: "Lack of face-to-face contact, and the distance interaction makes one feel bad."

The Threatening and Exploitative Nature of Cyberbullying

The threatening and exploitative context are other crucial traits that can be acquired by accessing private information, threatening to share it with the public, deleting things that are not theirs, and passing judgment without evidence. For instance, a participant said, "Exploitation using photos or videos or voice messages to request huge amounts of money to remove them is the worst thing." Another participant said, "Exploitation in public and threatening to reach the relative was so bad." In contrast, a third one recalled, "Using the private context to request immoral or intolerant things or to threaten the victim was challenging." Such actions of unauthorized distribution of personal material exacerbated emotional distress and fostered a continual feeling of susceptibility. "They said they would share my pictures if I did not do what they wanted. I felt blackmailed and exploited," one participant explained.

The Public Exposure and Wider Harm of Cyberbullying

Public and remaining possible nature of cyberbullying victimization emerged as a critical challenge to overcome such experiences, which appeared in 3 features, including quick spread, presence of many audiences, and direct psychosocial impacts. “The worst thing about it was happening in the public context and making others laugh at me...” is an example of the many-audience feature. Another participant reported that once harmful content was shared, it spread rapidly across online platforms, inhibiting the ability to move on and recover. “The spread of behavior in social media,” “Even if I delete or deactivate my account, people still remember what was posted,” some participants expressed.

Regarding the direct psychosocial impact of such public experience, when cyberbullying is directed explicitly to the psychosocial effects impacting an individual’s emotional status, social connections, and self-esteem, leading to feelings of inferiority and isolation, because a person tries to avoid others to prevent re-experiencing cyberbullying again. In this regard, participants expressed:

> *Cyberbullying impacted my self-esteem and caused fear of dealing with others to avoid re-experiencing it again, which impacts all aspects of life, like getting a job.*

Elements Influencing the Severity of Cyberbullying Experiences

Overview

When the participants were asked what they thought were the factors determining the severity of the cyberbullying effects, they mentioned several personal, social, and digital aspects that influence the intensity and duration of cyberbullying impacts.

Individual Vulnerability and Coping Capacity

This subtheme includes several individual characteristics, such as age, identity, self-confidence, psychological resilience, prior psychological problems, prior experience of cyber victimization, and lack of awareness of online security and regulations. Participants expressed that younger individuals or those with lower self-esteem are more pointedly affected by cybervictimization. While those with strong emotional regulation were more likely to cope, a participant recalled that “Older people have experience and know how to deal with cyberbullying; younger children are at higher risk.” Further examples that reflect the rest of the characteristics are: “Lack of confidence and weak personality intensify impact,” “being a victim of previous bullying experience.”

> *The awareness about the response to cyberbullying victimization, like informing about electronic crimes, blocking the bullies, and keeping accounts secure and not giving passwords to anyone, has a great role in strengthening victim response.*

Role of Others in Shaping the Cyberbullying Experience

This subtheme includes 4 aspects: social agreement, bystander and close people support, unhealthy social relationships and family conflicts, and the relationship with the perpetrator.

Regarding social agreement, participants discuss how cyberbullying begins with one individual and escalates as others join in, forming a larger group engaged in the behavior when the social context does not reject such behavior, leading the perpetrator to repeat the same behaviors due to the nature of social agreement. This quote is an example of “the social agreement, starting with one person, then others participate in the bullying, and it becomes a big group cyberbullying.” Social support arises as a protective factor against the impacts of cyberbullying. A participant said:

> *Lack of bystander support makes bullies think that they are correct... presence of support, especially emotional support from trustworthy people like family and friends, can minimize cyberbullying impacts.*

Those responses indicate that adolescents with supportive families, educators, or peers experienced less anxiety and faster healing.

Unhealthy social relationships and family conflicts worsen cyberbullying impact by adding extra emotional distress. For instance, a participant expressed that “What aggravates the bullying effects is the emotional pressure and the family conflict or problems.” The relationship with the perpetrator was mentioned as an essential factor that interferes with the bullying experience effect. Being close or related vs a stranger can elevate the adverse effects of cyberbullying: “Knowing the perpetrator... the relationship with him, if he is a close friend, relative, or a stranger, differs in the effects.” Additionally, societal expectations regarding shame and reputation frequently prevented teenagers, especially girls, from revealing incidents. “I did not inform my parents since I feared they would confiscate my phone or hold me responsible,” one participant stated.

Digital Environment as an Enabler of Cyberbullying

Many participants discussed other digital features that directly determine the severity of cyberbullying’s impacts, including the context of cyberbullying behavior, the tactics used, the purpose of cyberbullying, the number of bullies (one vs group), and the lack of regulations and penalties. Regarding the context of cyberbullying, the type of posted information can aggravate adverse effects because posting personal information to exploit others, sharing sensitive family secrets, or private photos or videos has more emotional impacts than general nonfamily-related information. For instance, a participant stated that “the type of shared information, private versus usual... posting the personal issues online so hurtful.” When it comes to tactics and targets of cyberbullying, the ways used to bully a victim (photos, videos, posts, or comments), the words used, the purpose of bullying (color, body image, or religion), the number of bullies (one vs group), and continuing out of the online context to in-person bullying are essential to determine adverse effects. A participant recalled:

> *...the ways used to bully victims influence severity of experience, it differs if bullies use images, videos, posts, or comments, and what kind of words are used.*

Another participant expressed that:

> *Targeting the body image or one of the innate characteristics that are difficult to change using*

XSL•FO
RenderX

> *hurtful wards... the loneliness effect and realizing that these things that I was bullied about are things that exist in me, and I cannot change them increase the severity of adverse effects on me.*
>
> *The situation was so terrible because not one but group of my classmates had bullied on me through hurtful wards in the class WhatsApp group, then they started to do the same in the school in front of many.*

Some participants mentioned the lack of educational sessions on how to deal with cyberbullying, the lack of protective regulations and rules (eg, no regulation of posts and their spread), and the level of expertise of the perpetrator, all of which are factors that affect how bullying impacts the victim. These quotes illustrate this: "...how expert the perpetrator is influences the impact because of his ability to use different techniques."

> *Lack of punishments for bullies, lack of knowledge how to respond, and lack of support for victims... There are no educational sessions on how to deal with cyberbullying.*

In conclusion, the study revealed the multifaceted nature of adolescents' experiences with cyberbullying. The findings highlight that beyond the digital realm, cyberbullying effects extend to affect psychological status and social functioning, including emotional distress, anxiety, cognitive disturbances, social withdrawal, and damaged trust. Key challenges in coping with cyberbullying were linked to the anonymity of perpetrators, the exploitative use of private information, and the public nature of online attacks, all of which intensified feelings of helplessness and humiliation. The presence of social support is a protective factor that facilitates recovery from cyberbullying victimization. The severity of these effects was influenced by personal vulnerability, social agreement and support, the nature of the relationship with the perpetrator, and digital factors such as the tactics used, the number of bullies involved, and the absence of regulations or accountability mechanisms. Together, these findings highlight the urgent need for targeted prevention, context-sensitive interventions, and educational initiatives to promote emotional resilience and online safety among Jordanian youth.

Discussion

Overview

This study added evidence on the effects of cyber victimization and elaborated further on the challenges and determinants of this experience. The results can be interpreted via the Stress–Diathesis Model, which suggests that psychological outcomes result from the interplay between environmental stressors and personal vulnerabilities [21,22]. Cyberbullying served as a major stressor in this study due to its ongoing presence, anonymity, public visibility, and exploitative nature. Participants' experiences vary based on factors such as individual coping abilities, resilience, and prior emotional vulnerabilities. Participants with limited coping resources seemed more vulnerable to anxiety, emotional suffering, and social isolation. Concurrently, social support from family, peers, and teachers served as a protective factor, mitigating the adverse psychological effects. These results indicate that the effect of cyberbullying is influenced not only by exposure but also by the complex interplay of digital stressors and personal vulnerabilities.

The findings provided an answer to the first research question about the effect of cyberbullying experience. According to the participants, cyber victimization mainly affects psychological health and social relationships, which are sometimes overlapping. This is in line with Sung [41], who states that cyberbullying impacts psychosocial adjustment, including mental health, self-esteem, and social relationships. The negative emotions that cyberbullying elicited ranged widely from wanting to avenge and retaliate to feeling sad, hurt, embarrassed, angry, humiliated, isolated, marginalized, and powerless. The findings are also consistent with a study that used data from a qualitative thematic analysis of several data sources considering the effects of cyberbullying; numerous people mentioned crying for extended periods and feeling upset, emotional, choked, crushed, hurt, and generally miserable [42].

Cyberbullying victimization as a stressful situation may lead to changes in the brain's internal structures, as shown by the discovery that cyberbullying victims have more severely disrupted cortisol reactivity [20] and altered emotional brain function [43]. Social isolation is one of the most severe effects of cyberbullying. It differs significantly from traditional bullying in that there are no limitations on when or where technology can be used for communication. Social isolation, increased suspicion, and signs of posttraumatic stress disorder may happen when cyberbullying tactics expose the victim's humiliation to an extensive audience viewing [44]. The lack of acceptance among their peers causes victims to feel lonely and socially isolated, have low self-esteem, and be depressed [45,46]. It can also cause stress-related disorders, problems with concentration and learning in school, emotional disorders, and even suicidal thoughts [46]. Thus, developing effective prevention and intervention strategies to support those affected is crucial.

The analysis supported the second question that participants' narratives revealed persistent barriers to overcoming cyberbullying victimization. Participants shared a wide range of thoughts on the most challenging part of their cyberbullying experience. They described those difficulties in a manner that reflects the unique cyberbullying attributes of anonymity, publicity, and threatening context. Cyberbullying possesses distinctive traits due to its online nature and lack of face-to-face contact, such as its persistent nature, broad audience reach, and anonymity, distinguishing it from traditional bullying [47]. Anonymity, particularly in public online spaces, may hinder prevention efforts as perpetrators can remain unidentified. Anonymity exacerbates feelings of helplessness and perceived power imbalances in cyberbullying situations, pushing victims to keep their experiences silent without reporting. Victims may feel powerless and vulnerable when perpetrators possess embarrassing or harmful material that cannot be controlled and published online at any time in front of many people [48]. However, earlier studies, predating 2010, did not prioritize these characteristics, as evidenced by the systematic review by Berne et al [49].

XSL•FO
RenderX

Participants stated that the threatening and exploitative context of cyberbullying is one of the critical reasons why they consider this experience challenging, primarily when the bully uses private information to request immoral or intolerable things or to threaten the victims in public and threaten to reach their relatives. Also, accusing victims and passing judgment on them for things that are not true without evidence leads to feelings of inadequacy and altered psychosocial functioning, including suicidal thoughts and avoidance of social interaction to avert re-experiencing bullying. Thus, it is necessary to develop interventions to overcome such situations. For example, using celebrity endorsements is effective in highlighting the effects of cyberbullying and favoring an inclusive strategy that educates on prevention skills, promotes reporting, allows anonymous online reporting, and revokes internet privileges for perpetrators, where mandatory reporting, suspensions, or police involvement predicted a significant decrease in support from uninvolved students, witnesses, victims, and perpetrators [50].

The study findings illustrated that personal and interpersonal factors significantly shape how severe the impact of cyberbullying is on adolescents, which answers the third question. Adolescents in Jordan stated that the severity determinants of experience impacts are an integration of many personal, social, and digital factors related to cyberbullying behavior. According to participants, with age, people gain more skills and knowledge to deal with bullying; personality and beliefs, psychological strength, awareness of online security, and previous bullying experience are the most personal determinants of cyberbullying effects. Subsequently, younger children need more interventions that focus on enhancing their awareness of and skills to deal with cyberbullying and online websites, specifically school-based intervention programs [51] that target emotional intelligence and strengthen psychological well-being.

The participants stated that some social factors determine the severity of cyberbullying effects as well, such as social acceptance, lack of support, family conflicts, and relationship with the bully. Given the reality that adolescents experience marked patterns of cyberbullying victimization and perpetration based on individual and social support factors [52]. Social support is essential for victims of cyberbullying because it can protect them from the damaging effects of bullying. Individuals are more able to handle the strain and emotional anguish brought on by cyberbullying when they have supportive relationships with friends, family, or peers [53]. In addition to offering practical help, emotional validation, and a sense of community, social support can make victims feel less alone and more resilient in the face of bullying [54]. Having supportive relationships can also motivate victims to report incidents, seek assistance, and take precautions to stay safe online when they believe they have friends who support them in solving problems, regaining their confidence, and resuming social interactions in their surroundings [55]. In general, social support is essential for reducing the negative impacts of cyberbullying and enhancing the well-being of its victims. However, there is low perceived family and peer social support among youth [56], making this an essential area for intervention. As youth spend a long time online, initiatives are needed to promote online help-seeking and empower parents and peers to support their well-being [57].

Lastly, participants talked about some digital factors that are directly related to the nature of cyberbullying behavior, which were essential in determining the severity of victimization. The type of posted information can aggravate adverse effects because posting personal information to exploit others, sharing sensitive family secrets, or sharing private photos or videos has a greater emotional impact than general, nonfamily-related information. On the other hand, the ways used to bully victims (photos, videos, posts, or comments), the words used, the target of bullying (color, body image, or religion), the number of bullies (one vs group), and continuing out of online context to in-person bullying are essential determinants of adverse effects.

Implications

The findings of this study underscore the urgent need for culturally responsive victim-centered clinical and technology supported interventions, policy reforms, and accessible mental health services to mitigate the psychological and social harms of cyberbullying on adolescents. Raising awareness of harmful content and the dangers of sharing personal information online should be prioritized through school-based education and parental guidance. Schools need targeted interventions, such as implementing digital safety and mental health programs that include emotional regulation training and peer-support methods, in light of the identified effects of distress, isolation, and relationship difficulties, taking into consideration the sociocultural context of adolescents and parents, such as communication norms and culturally specific views on online conduct. Family-based interventions are essential, as parents play important protective roles. These interventions should focus on open communication, digital literacy, and supportive oversight methods that can enhance teenagers' ability to cope and their resilience when dealing with cyberbullying. Mobile apps or online platforms offering psychoeducational resources could enhance parental understanding and facilitate early recognition of distress related to cyberbullying, effectively.

Health care providers, especially nurses and public health professionals, have a critical clinical role in routine screening for bullying during medical visits, such as including questions on intake forms [51], which can facilitate disclosure and early intervention. Following the COVID-19 pandemic, increases in online activity have altered the landscape of cyberbullying, highlighting the need for updated, trauma-informed care policies [58]. Moreover, integrating innovative tools, such as narrative-based audio-visual interventions, into prevention programs may enhance adolescents' engagement and emotional processing. For instance, initiatives like programs that have shown that multimedia storytelling can foster empathy and resilience [59,60]. In line with scalable digital mental health strategies [61], interventions could benefit from using mobile health technologies, digital counseling services delivered through schools, and chatbot-assisted psychoeducation to deliver prompt, accessible assistance. Future studies should be built on longitudinal, intervention-based designs to explore the efficacy and cultural relevance of these technology-driven approaches across various social and cultural contexts.

XSL•FO
RenderX

Limitations

Although this study provides valuable insights into the contexts and perspectives surrounding cyberbullying victimization among adolescents in Jordan, several limitations should be acknowledged. First, data collection relied solely on 3 open-ended narrative questions within a survey, which may have limited the depth and nuance of participants' responses in reflecting subtle coping strategies, long-term effects, or intricate family and school interactions. Future research could benefit from using in-depth interviews or focus groups to allow adolescents' experiences to be expressed more richly and in greater detail. Second, the sample was drawn exclusively from central and northern Jordan, limiting the generalizability of the findings to adolescents in other regions. Environmental, cultural, and technological factors in southern or rural areas may shape cyberbullying experiences differently.

Additionally, the use of self-report methods may introduce bias due to participants' desire to present themselves in a favorable light or their reluctance to disclose sensitive information. The timing of data collection during the school year may also have influenced responses, as experiences of cyberbullying can fluctuate depending on school-related stress and peer interactions. To strengthen generalizability and validity in future research, studies should aim to include more diverse regional samples, consider longitudinal designs to capture temporal patterns, and incorporate mixed methods approaches that combine narrative inquiry with quantitative measures. Future studies should also explore how gender may shape experiences, interpretations, and coping strategies related to cyberbullying.

Conclusion

This study provides a novel and context-specific contribution to the understanding of cyberbullying's psychological and social impact on adolescents in Jordan, a region where such research remains limited. Our findings illuminate how the anonymity of perpetrators, the exploitative nature of online threats, and the public exposure of cyberbullying significantly amplify adolescents' emotional distress, social withdrawal, and behavioral disruption. Notably, the results also highlight how the absence of moral courage and bystander intervention, shaped by social dynamics, personal vulnerabilities, and unhealthy relationships, intensifies victims' feelings of isolation and helplessness. This underscores the need to incorporate frameworks that foster moral courage and active defense behaviors into intervention strategies, which are currently underexplored. By addressing these gaps, this study contributes to a victim-centered understanding of cyberbullying and offers direction for targeted, culturally relevant prevention efforts. Future research should build on these insights by using in-depth interviews or longitudinal designs to explore long-term effects and associated outcomes such as coping mechanisms, academic disruption, self-harm, and other high-risk behaviors. These extensions would deepen our understanding of how early experiences with cyberbullying shape adolescent development and inform more holistic and trauma-informed support systems.

Abstract

Background: Attentional functioning in childhood emerges from the interaction between cognitive, behavioral, and emotional processes. Children with these vulnerabilities frequently exhibit executive function deficits, including working memory, inhibitory control, cognitive flexibility, and processing speed, which compromise the ability to regulate attention, plan, and organize tasks, and modulate emotional responses, highlighting the need for screening approaches that integrate multiple dimensions of child functioning.

Objective: This study aimed to develop and evaluate an automated, real-time, and simultaneous multimodal screening approach capable of identifying individualized cognitive-emotional-attentional profiles and behavior patterns in children through the integration of oculomotor, emotional, and neuropsychological measures, supporting earlier detection and personalized interventions.

Methods: A cross-sectional design was used to assess a sample of 260 children aged 7-15 years through a multimodal approach integrating neuropsychological tests (2- and 3-symbol cancellation tasks from the Coimbra Neuropsychological Assessment Battery; Trail Making Test Parts A and B), eye-tracking metrics, and automated facial emotion recognition during rapid naming and emotion recognition tasks. Oculomotor, emotional, and cognitive data were captured simultaneously and in real time, enabling dynamic characterization of cognitive-emotional interactions at millisecond resolution during task performance. A machine learning pipeline based on a random forest classifier, with a gradient boosting surrogate model used for Shapley additive explanations interpretability analyses, analyzed these data to differentiate children with lower attentional performance from children with normative attentional performance.

Results: The random forest classifier achieved the best performance in the exploratory 80/20 hold-out evaluation (area under the receiver operating characteristic curve=0.9527; F_2-score=0.9055; accuracy=94.2%; sensitivity=88.5%; specificity=100%). To validate the absence of test-set selection bias, a nested 5×5 stratified cross-validation was conducted with model selection based exclusively on inner-fold F_2-scores. The negligible difference between nested cross-validated area under the curve (AUC; mean 0.9506, SD 0.0378) and the hold-out AUC (ΔAUC=0.0021) confirmed that the original result was not inflated. Children with lower attentional performance showed increased emotional reactivity, greater gaze instability, fragmented visual exploration patterns, higher variability in fixation behavior, and more frequent impulsive saccadic movements during emotionally salient tasks. Anger and fear stimuli showed stronger discriminative value across attentional performance levels, suggesting that emotional processing modulates attentional allocation.

XSL•FO
RenderX

Conclusions: The simultaneous, real-time capture of eye-tracking, emotion recognition, and neuropsychological data, combined with post hoc analysis within an interpretable machine learning framework, may support the identification of behavioral patterns associated with attentional functioning in children. This multimodal approach provides ecologically grounded and behavior-centered indicators that may support future screening and intervention strategies in educational and clinical contexts.

Introduction

Attention-deficit/hyperactivity disorder (ADHD) is a neurodevelopmental condition with a global prevalence estimated at approximately 8% in children and adolescents [1], characterized by persistent patterns of inattention, hyperactivity, and impulsivity that interfere with functioning or development [2]. A diagnosis of ADHD requires a full clinical evaluation that cannot be based solely on screening measures. In addition to the core symptoms, impairments are also observed in executive functions (EFs; including working memory, inhibitory control, and cognitive flexibility), as well as emotion dysregulation and attentional processes (sustained/selective attention), which collectively contribute to academic, social, and emotional difficulties [3-5].

The EFs are a set of interrelated higher-order cognitive processes that emerge and develop during early childhood, supporting attention regulation, suppression of distractions, and the planning and coordination of goal-directed tasks [3,5,6]. Key components include working memory (holding and manipulating information), inhibitory control (suppressing impulsive responses), cognitive flexibility (the ability to shift perspectives), and processing speed (the efficiency of cognitive processing). These foundational skills are crucial for many developmental outcomes, including social, emotional, and academic achievement [7,8]. Early childhood represents a sensitive period for the maturation of executive systems, particularly within the prefrontal cortex, which underpins these functions. Deficits in EF during this period are associated with decreased resilience, lower self-regulatory efficacy, and increased behavioral problems in school-age children, and are longitudinally linked to increased risk of neurodevelopmental difficulties [9-11].

A growing body of research highlights the role of EFs in emotion regulation. A comprehensive study found that working memory, inhibitory control, cognitive flexibility, and processing speed play an important role in the regulation of emotional responses and behavioral adaptation [12]. New neurodevelopmental evidence suggests reduced spontaneous activity in frontal regions associated with executive and inhibitory control, while adolescents exhibit more widespread alterations, including cerebellar and sensorimotor areas, suggesting age-dependent differences [13]. Longitudinal evidence further shows that EF and processing speed are closely linked to attentional difficulties, each contributing uniquely to inattentive behaviors [14]. These executive deficits are closely linked to emotional dysregulation, including increased reactivity and difficulties in emotion recognition, and are associated with elevated risk for anxiety and mood difficulties [4,15].

Despite growing recognition of attentional functioning as a multimodal phenomenon, diagnosing ADHD remains challenging, often relying on clinical interviews, behavioral observations, and rating scales that may be influenced by contextual and interpretative biases. As a result, growing attention has been given to data-driven, noninvasive technologies to complement traditional assessments [16]. One such technology is eye-tracking, which has emerged as a promising tool for the objective assessment of attentional mechanisms across cognitive, clinical, and developmental contexts [17,18]. Visual attention is dynamically expressed through eye movements, which reflect how visual information is organized and processed during task performance. Eye movements are therefore not merely motor responses, but functional indicators of attentional allocation, inhibitory control, visual exploration strategies, and visual-cognitive regulation [19,20]. These processes can be objectively examined through eye-movement patterns, including fixation stability, gaze dispersion, saccadic regulation, and visual scanning organization, which provide measurable indicators of attentional control and cognitive efficiency [21]. Children with lower attentional performance have been shown to exhibit atypical gaze patterns, including reduced attention to others' eyes during emotion recognition tasks [22], as well as broader difficulties in processing emotional scenes [23].

According to Barkley's [24] theoretical model, ADHD may arise from a primary deficit in behavioral inhibition, disrupting the development of EFs such as working memory, self-directed speech, emotion regulation, and planning. Recent eye-tracking studies have provided further insight into visual attention and oculomotor control in children, advancing understanding of underlying neurocognitive processes [25,26]. However, traditional assessment approaches often fail to capture the dynamic, moment-to-moment interplay between gaze behavior and emotional reactivity that characterizes real-world attentional functioning [27-29]. Addressing these gaps, this study aims to develop a rapid and ecologically valid method for identifying individualized cognitive-emotional-attentional profiles in children and adolescents, grounded in the premise that attentional functioning is inherently linked to emotional and social cognition.

By integrating eye-tracking data with measures of EF and emotional regulation, this study adopts a multimodal neurovisual perspective on attentional functioning, aiming to characterize behavioral profiles associated with differences in

XSL•FO
RenderX

visual-attentional regulation, emotional processing, and cognitive control. To this end, the study uses a machine learning (ML) classification approach in which multiple algorithms are used.

The random forest classifier was used as the primary model within a multimodal analytical framework integrating neuropsychological measures, emotion-processing tasks, and eye-tracking indicators to characterize attentional-functioning profiles in children and adolescents. A key methodological feature of this study is the integration of oculomotor, facial-emotional, and cognitive data collected within a single platform, enabling the analysis of multimodal behavioral streams with high temporal precision. The use of ML algorithms, combined with explainability techniques such as Shapley additive explanations (SHAP), may support strong predictive performance while providing interpretable outputs in clinical and educational settings [30]. However, it should be emphasized that the approach used in this study characterizes behavioral patterns of attentional functioning rather than establishing clinical classifications and is therefore limited to a screening process based on psychometric and behavioral indicators, not representing a clinical diagnosis, which requires a comprehensive multidisciplinary assessment by qualified professionals. In this study, behavioral profiles refer to recurring multimodal patterns derived from neuropsychological, oculomotor, and emotional measures associated with different levels of attentional functioning. These profiles are identified through a data-driven approach and do not represent clinical categories or diagnostic classifications; rather, they reflect variability in attentional, emotional, and visual-processing dynamics during task performance.

Building on the previous theoretical and empirical foundations, the following hypotheses were formulated:

- H1: Children with lower attentional performance will exhibit less efficient and more unstable oculomotor patterns compared to children with higher attentional performance, reflected in greater gaze dispersion, increased variability in fixation durations, less organized visual exploration, and a higher frequency of impulsive saccadic movements;
- H2: Emotional stimuli are expected to differentially affect attentional allocation, with children showing lower attentional performance exhibiting distinct gaze patterns and emotional responses compared to children with higher attentional performance.
- H3: Children with lower attentional performance will exhibit weaker integration between gaze behavior and facial emotional expression patterns, reflected in greater variability across both domains.

This study aims to advance understanding of the mechanisms underlying attentional and emotional processing and to inform the development of tailored interventions based on cognitive and emotional profiles. By leveraging behavioral and emotional data, this approach enables faster and more consistent evaluations [31]. By integrating eye-tracking, emotion analysis, and cognitive measures collected in real time, the proposed framework provides a more automated screening model for identifying subtle behavioral patterns through multimodal analysis.

Methods

Participants and Procedure

A total of 260 children aged 7-15 (mean 10.36, SD 2.50; median 10, IQR 8-12) years from a public elementary school in the northern region of Portugal participated in the study. Of the total participants, 142 (54.6%) were male. The age distribution was mainly concentrated among children aged 7 years (n=46, 17.7%), 12 years (n=45, 17.3%), and 8 years (n=41, 15.8%), while the remaining participants were distributed across the other age groups within the 7-15-year range. Regarding attentional performance, the sample was evenly distributed, with 130 children classified as having adequate attentional performance (“good”) and 130 classified as having poorer attentional performance (“poor”), each group representing 50% of the sample. A balanced distribution was obtained through a case-control sampling procedure, preserving the ecological validity of both groups while ensuring methodological rigor in the context of ML classification. Sex distribution was also comparable between groups: the good attentional performance group comprised 60 female and 70 male individuals, whereas the lower attentional performance group comprised 58 female and 72 male individuals.

Inclusion criteria comprised children aged 7-15 years attending a regular school setting. Exclusion criteria were based on the student’s school records: (1) not having Portuguese as a first language, (2) inability to recognize the alphabet, (3) presence of any motor impairments that could interfere with task performance, and (4) intellectual disability or developmental delay. Only participants with complete data across all experimental conditions were included in the final sample, ensuring consistency and robustness for subsequent multimodal and ML analyses.

Eye movements were recorded using the Tobii Eye Tracker 4C, a remote, infrared-based binocular eye-tracking system operating at 90 Hz. According to manufacturer specifications, the system provides spatial accuracy of approximately 0.4°-0.5° and a precision of less than 0.2° root mean square under optimal calibration conditions.

All assessments were conducted under standardized environmental conditions, including controlled ambient lighting and a fixed viewing distance of approximately 60 cm between the participant and the display monitor. Participants were seated comfortably, and a standardized 9-point calibration procedure was performed individually prior to each assessment session. Recalibration was undertaken whenever tracking quality was deemed suboptimal. Only recordings demonstrating stable binocular tracking and complete data acquisition across all experimental conditions were retained for subsequent analysis.

Experimental tasks were administered under fixed presentation parameters within the Neurobiosensorial platform, which integrates real-time eye-tracking with automated facial emotion recognition during rapid naming and emotional face recognition paradigms. Facial emotional responses were recorded via

XSL•FO
RenderX

webcam and analyzed using the HSE-AffectNet framework embedded in the platform. The system was designed to detect basic facial emotions (happiness, sadness, anger, fear, and surprise), which are widely regarded as universal expressions within Ekman's theoretical framework and are comparatively less dependent on linguistic processing.

The assessment protocol was administered individually by a trained psychologist during a single session lasting approximately 45-60 minutes, in the absence of caregivers. Although no formal breaks were scheduled, task demands were systematically alternated to mitigate fatigue and sustain participant engagement. The protocol was previously piloted to ensure developmental appropriateness for the target age group, thereby supporting standardized data acquisition while minimizing potential sources of external interference.

The protocol followed a fixed sequence: (1) 2- and 3-symbol cancellation tasks from the Coimbra Neuropsychological Assessment Battery (CNAB), (2) Trail Making Test (TMT), Parts A and B, and (3) eye-tracking–based tasks, including Rapid Naming of Shapes and Colors and emotion recognition. In line with the study's hypotheses, oculomotor indices derived from eye-tracking (eg, fixation variability, gaze dispersion, and saccadic patterns) were used to capture attentional stability and visual efficiency, while emotion-related measures were used to examine the modulation of attention by emotionally salient stimuli.

Cutoff scores from assessment instruments were used to support screening-based interpretations of attentional difficulties, applied solely for research purposes and not for clinical diagnosis. This distinction is critical given the study's focus on characterizing variability in attentional functioning rather than establishing diagnostic categories.

Ethical Considerations

The study was conducted in accordance with the Declaration of Helsinki and was approved by the Clinical Review Board, the Ministry of Education (approval number 0786500001), and the school principal. Parental or legal guardian written consent was obtained for all participants, authorizing the use of the children's data for research purposes. Participation was voluntary with no compensation, and confidentiality and the right to withdraw at any stage were guaranteed. All data were anonymized and deidentified prior to analysis, and appropriate data protection measures were implemented to safeguard participants' information.

Assessment Instruments

Sociodemographic Questionnaire

This questionnaire was specifically designed for the purpose of this study to characterize the sample (eg, age, gender, educational level, and parental occupational status).

Neuropsychological Assessment

The Cancellation Scale From the CNAB

This subscale evaluated attention and EFs in children [32]. The task required the child to visually scan a sheet filled with various symbols and mark specific target stimuli within a specified time limit. Performance was measured based on the number of correctly identified targets and the number of commission and omission errors. Higher accuracy and fewer errors indicate better attentional control and executive functioning.

In the original validation studies, the CNAB Cancellation subtests showed adequate psychometric properties for the pediatric population, including satisfactory internal consistency (Cronbach α values ranging from 0.78 to 0.86 across age groups) and good interrater reliability (intraclass correlation coefficients >0.90). Construct validity was supported by significant correlations with other established measures of attention and processing speed, and discriminant validity was evidenced by the subtest's ability to differentiate between typically developing children and those with attention-related disorders [32]. In this study, only the 2- and 3-symbol cancellation tasks from the CNAB were used, each consisting of a single trial; therefore, internal consistency indices such as Cronbach α could not be calculated. Evidence of reliability for the current application relied on prior validation studies of the CNAB, which have reported acceptable stability and sensitivity coefficients for these tasks in similar populations [32]. A screening cutoff score of 7 or below was also used as an indicator of potential attentional difficulties [32].

The TMT (CNAB Subscale)

This subscale [32] assessed attention and EFs in children and consisted of 2 parts: Trail A and Trail B. In Trail A, the child is asked to draw lines connecting numbers in ascending order (eg, 1-2-3...), while in Trail B (applied to children aged 7 years or older, as it requires knowledge of the alphabet), the task becomes more complex by requiring the child to alternate between numbers and letters in ascending order (eg, 1-A-2-B...). Time to complete the instrument is measured in seconds. Errors are not directly scored, but they can influence overall performance, as the examiner intervenes when a mistake occurs by pointing out the last correct response, thereby increasing completion time. Each part of the Trail Task consists of a single trial; thus, internal consistency indices could not be computed. Moreover, in the absence of a test-retest design, it was not possible to directly assess temporal stability. Reliability evidence for the present application is therefore based on previously published psychometric studies of the TMT, which have shown satisfactory stability and validity in similar populations [32]. In this study, performance was interpreted using established screening cutoff scores, with values <7 indicating poorer attention performance [32].

The Rapid Automatized Naming of Shapes and Colors (CNAB Subscale)

This instrument [32] was integrated with eye-tracking and facial emotion recognition tools. The child was presented with a visual sheet containing a sequence of shapes (triangles, circles, and squares) in different colors (yellow, green, and blue) and was asked to name each shape and its corresponding color line by line, as quickly and accurately as possible. During task performance, an eye-tracker recorded oculomotor activity to analyze visual exploration patterns, including fixation count and duration, regressions, and loss of sequence. Raw gaze data were processed using a velocity-based fixation classification

XSL•FO
RenderX

algorithm (Identification by Velocity Threshold) with a minimum fixation duration of 100 ms. Additional metrics included saccadic amplitude, interfixation interval variability, and the coefficient of variation of fixation duration. These measures index attentional stability, visual exploration efficiency, and visual-cognitive organization. Composite indicators of visual efficiency and attentional instability were derived from gaze dispersion, fixation variability, and saccadic transition patterns. Simultaneously, a facial emotion recognition system records spontaneously displayed emotions, providing insight into the affective experience associated with cognitive performance. This combined approach may support a multimodal examination of attentional and emotional processes during rapid visual-verbal tasks. No screening cutoff score was used; instead, comparative analyses were based on the distribution of total response times across participants. Children were divided into groups representing higher and lower task performance, determined by e-based segmentation of total naming time (with the lowest quartile representing faster, more efficient performance and the highest quartile indicating slower processing). Between-group comparisons were then conducted to examine differences in accuracy, eye-tracking parameters (eg, fixation count, fixation duration, and regressions), and patterns of emotional expression.

Emotional Processing Multimodal Assessment

Emotion Recognition

This task was performed by the Neurobiosensorial program [33]. This platform was specifically designed to enable the simultaneous, real-time recording of eye movements and facial emotional responses within a single integrated environment. This program tracks eye movements and pinpoints eye position while executing a specific task (emotion naming), while detecting emotional responses [33]. Eye-tracking measures eye movement at millisecond intervals, providing insight into the cognitive processes involved in task interpretation. The participant's facial expressions are analyzed using HSE-AffectNet and webcam image analysis combined with AI technology to identify emotions experienced throughout the task [34]. The program's interface relies on 27 simple facial recognition points (eg, pupils, eyebrows, and the nose area) as reference markers. During each task, whether it involves a higher cognitive demand or emotional identification, a list of the emotions felt by the child throughout the experience is generated as an outcome [34].

Emotion Naming

This task was based on the emotion recognition paradigm developed by Paul Ekman, adapted to assess children's ability to identify basic facial emotions [35]. The task focuses on 5 fundamental emotions: happiness, sadness, anger, surprise, and fear. In each trial, the child is presented with 4 images of facial expressions, each depicting a distinct emotion. The child is then asked to identify which images correspond to the target emotion verbally indicated by the examiner (eg, "Which face shows sadness?"). The primary variables are the ocular movement patterns and the emotions experienced by the participants, recorded simultaneously and in real time using an eye-tracking system and a camera-based facial emotion recognition system. This synchronized, dual-stream capture allows direct examination of moment-to-moment interactions between where a child looks and what emotional state they express. While the child is asked to identify the target emotion among the 4 images, the system captures their visual scanning paths, fixation points, and saccades, providing insight into the attentional strategies used during emotion recognition. Raw gaze data were processed using a velocity-based fixation classification algorithm (Identification by Velocity Threshold), with a minimum fixation duration threshold of 100 ms [34]. This procedure segmented gaze data into fixations and saccades based on movement velocity profiles.

Areas of interest (AOIs) were defined based on the spatial structure of each task. In the rapid automatized naming task, AOIs corresponded to the stimulus grid and sequential naming regions [36]. In the emotion recognition task, AOIs were defined around facial stimuli, including key regions such as the eyes, mouth, and overall face, given their relevance for social and emotional processing. A tolerance margin was applied to account for minor tracking variability [36].

Composite indicators of attentional instability and visual efficiency were derived from gaze dispersion, fixation variability, and saccadic transition patterns, capturing higher-order interactions between visual attention, emotional reactivity, and oculomotor regulation. Eye-tracking data were analyzed using custom computational pipelines. Extracted metrics included fixation count (total fixations within task-relevant AOIs), mean fixation duration (attentional engagement), saccadic amplitude (visual exploration dynamics), and gaze dispersion (spatial distribution of attention) [35,36].

Additionally, the facial emotion recognition system recorded the spontaneous emotional reactions elicited in the child while observing the stimuli, assessing the child's ability to recognize emotions and their affective responses, as well as the visual processing behaviors associated with each emotion. Some participants may spend more time on the eye region, while others may focus on the mouth or the overall facial contour. Additionally, the number and sequence of oculomotor metrics can differ depending on attentional control, processing speed, and familiarity with emotional expressions. This natural variability affects the consistency of the data when aggregated across participants; however, it remains meaningful as it reflects genuine differences in attentional and cognitive processing styles [34,36].

Data Analysis

Overview

Two significant sources were used: (1) clinical test results (Cancellation, Trail A, and Trail B) providing screening-based attentional-performance labels (1=lower attentional performance, 0=typical attentional performance) and (2) behavioral metrics collected from eye-tracking and emotion recognition during 6 tasks: "Rapid Naming of Shapes and Colors-NRFC)," "anger," "joy," "sadness," "fear," and "surprise." A child was included only if all metrics were available across all tasks.

A total of 30 variables selected from an initial set of 61 engineered features were used in the final model. Each variable

XSL•FO
RenderX

reflects cognitive-emotional interaction patterns. The features were selected spanning 5 behavioral domains: (1) oculomotor and attentional metrics derived from eye-tracking (eg, gaze path length, dispersion, fixation duration variability, interfixation interval variability, and visual efficiency), (2) emotion-specific expression and gaze features (eg, expression duration, dwell time, and gaze allocation per emotional category), (3) aggregated emotional indices (eg, emotional intensity, transition rate, valence balance, emotion bias duration, and number of active emotions), (4) composite cognitive-emotional indices (Attentional Instability Index, Gaze-Emotion Congruence Index, Emotional Reactivity Index, Visual Efficiency Index), and (5) a demographic covariate (age). These indices represent multimodal neurobehavioral markers integrating visual-attentional, emotional, and oculomotor dimensions.

Preprocessing

The raw integrated dataset contained variables for each child, representing both aggregated and emotion-specific behavioral metrics. No missing values were present in the final preprocessed dataset. The final dataset comprised 260 participants, with a balanced distribution across groups (130 with attentional difficulties; 130 with typical performance). The data pipeline followed a structured three-step procedure prior to model training:

- Step 1: data cleaning and preprocessing. Categorical variables were encoded using one-hot encoding. Missing values in fixation-related metrics were encoded with zeros to ensure dataset completeness and maintain consistency across participants. During this step, absent behavioral events, such as fixations in a stimulus zone not visited by a given participant, were assigned a value of zero, reflecting the absence of that behavior rather than a measurement gap. This domain-appropriate substitution resulted in a complete feature matrix with no missing values at the modeling stage. This preprocessing stage produced a clean, analysis-ready dataset.
- Step 2: feature engineering. Behavioral metrics derived from eye-tracking and emotion recognition were aggregated at the participant level using summary statistics (mean and SD) across trials. In addition, composite indices were computed to capture higher-order cognitive-emotional processes, including the Attentional Instability Index, Oculomotor Control Index, Emotional Reactivity Index, and Visual Efficiency Index). This process resulted in an initial feature set of 61 variables.
- Step 3: feature selection. Feature selection was conducted using mutual information scoring combined with redundancy filtering (correlation threshold $|r|<0.80$). This procedure yielded a final set of 30 features spanning oculomotor attention metrics, emotion-specific gaze and expression variables, aggregated emotional indices, composite cognitive-emotional indices, and age. All feature selection procedures were performed exclusively on the training set to prevent information leakage.

The final dataset was partitioned into training (n=208, 80%) and testing (n=52, 20%) subsets using a stratified split (random state=42) to preserve class proportions. The held-out test set was strictly excluded from preprocessing, fitting, feature selection, and hyperparameter optimization procedures.

ML Model Definition

The classification model was based on 7 classification architectures that were trained and compared, including 5 individual learners—gradient boosting, extreme gradient boosting (XGBoost), light gradient boosting machine (LightGBM), random forest, and support vector machine (SVM)—as well as 2 ensemble strategies: a soft-voting ensemble combining the top 3 models based on cross-validated area under the receiver operating characteristic curve (AUC-ROC; random forest, XGBoost, and gradient boosting), and a stacking ensemble using a logistic regression meta-learner trained on out-of-fold predictions from all base models.

Hyperparameters were independently optimized using Optuna (Bayesian optimization, tree-structured Parzen estimator, 15 trials per model), evaluated via 5-fold stratified cross-validation AUC-ROC on the training set. Optimized hyperparameters and corresponding AUC-ROC scores are reported in Table 1. A 5×3 repeated stratified K-fold was additionally applied to the training data to assess hyperparameter stability; the unbiased performance estimate is provided by the nested 5×5 cross-validation described below.

[e]AUC: area under the curve.

[f]RF: random forest.

[g]XGB: extreme gradient boosting.

[h]GBM: gradient boosting machine.

Model generalization was estimated using a 5×3 repeated stratified K-fold cross-validation strategy applied exclusively to the training set (n=208). This procedure was used to estimate hyperparameter stability during model development. Repeating the 5-fold procedure 3 times (15 folds total) reduces the variance of the performance estimate and provides a more robust basis for comparing models during training.

Although random forest did not achieve the highest cross-validated area under the curve (AUC-CV; AUC-CV=0.9528; full rankings in Table 1), it was selected as the primary model based on its F_2-score (0.9055) and zero false positives (FPs) in the exploratory 80/20 hold-out evaluation (Table 2). The absence of test-set inflation was confirmed by nested 5×5 cross-validation (area under the curve [AUC]: mean 0.9506, SD 0.0378; ΔAUC: mean 0.0021, SD 0.0378).

The random forest classifier was selected as the primary screening framework based on its F_2-score (0.9055) and zero FPs on the held-out test set. The F_2-score weights recall twice as much as precision, prioritizing clinical sensitivity; the cost of a missed lower-attentional-performance case (false negative [FN]) substantially exceeds that of an unnecessary referral (FP). Although gradient boosting achieved the highest cross-validated AUC, the random forest demonstrated comparable discrimination while providing a more favorable balance between sensitivity and specificity for screening. Its robustness was further confirmed through nested 5×5 cross-validation, achieving a mean AUC-ROC of 0.9506 (SD 0.0378), F_2-score of 0.8953 (SD 0.0664), recall (sensitivity) of 0.8923 (SD 0.0877), specificity of 0.9154 (SD 0.0740), and accuracy of 0.9038 (SD 0.0408). The minimal difference between the nested cross-validation AUC and the held-out test AUC (ΔAUC=0.0021, smaller than the cross-validation SD) indicates that model performance was stable and showed no evidence of performance inflation, supporting its selection as the final screening framework. LightGBM (AUC-CV=0.9614) produced one FP and a lower F_2-score (0.8984) on the test set, making it suboptimal for clinical screening where minimizing false referrals is a priority. Among all models with FP=0 and F_2-score=0.9055 (gradient boosting, voting ensemble, stacking ensemble, and random forest), the random forest achieved the highest test-set AUC-ROC. A gradient boosting model with identical features and data split was trained as a surrogate solely for SHAP interpretability analysis, as TreeExplainer requires direct access to the underlying tree structure.

Training and Validation Strategy

The held-out test set was not used during preprocessing, feature selection, or hyperparameter optimization. In the exploratory phase, model selection was informed by F_2-score and the false-positive rate observed on the hold-out set. The absence of test-set inflation was subsequently confirmed by nested 5×5 cross-validation (ΔAUC: mean 0.0021, SD 0.0378).

Each model was fitted on the full training set (n=208) using its Optuna-optimized hyperparameters. Final evaluation was performed once on the held-out test set (n=52, 26 per class) using the decision threshold optimized on the training cross-validation folds. Performance was assessed using AUC-ROC (threshold-independent), accuracy, precision, recall (sensitivity), specificity, F_1-score, and F_2-score. Recall was designated as the clinically primary metric, with F_2-score used for model selection.

In addition, a threshold sensitivity analysis was conducted across 9 decision thresholds (0.25 to 0.65 in steps of 0.05) for the primary model, to characterize the precision-recall trade-off and support clinical deployment decisions for different use cases (mass screening vs diagnostic confirmation).

Results

Classification Performance

Among the 7 candidate models, random forest, gradient boosting, voting ensemble, and stacking ensemble all achieved F_2-score=0.9055 with 0 FPs; random forest was selected for its highest AUC-ROC within this group. On the held-out test set (n=52), the random forest classifier (threshold=0.48,

XSL•FO
RenderX

Optuna-optimized) achieved an AUC-ROC of 0.9527, accuracy of 94.23%, precision of 100%, recall of 88.46%, and F_2-score of 0.9055 (Table 2). Every child with typical attentional performance was correctly excluded (FP=0); 3 children with lower attentional performance were missed (FN=3, FN rate=11.54%). Nested 5×5 cross-validation confirmed the absence of test-set inflation (AUC: mean 0.9506, SD 0.0378; ΔAUC=0.0021), supporting the validity of the reported estimates.

Sensitivity Analysis

To assess whether the facial expression confidence score reflected a genuine behavioral signal or acquisition-quality effects, a sensitivity analysis was conducted comparing the full model against a reduced version excluding this feature, with all preprocessing, hyperparameter optimization, and evaluation procedures kept identical. Classification performance remained essentially unchanged (ΔAUC=0.000; Δrecall=0.000; n=52), and SHAP-based feature rankings showed high stability (Spearman ρ=0.959; P<.001; 8/10 top features identical), indicating that the model's predictive behavior does not depend on this feature and is unlikely to be driven by acquisition-quality differences. Full results are presented in Table S1 in Multimedia Appendix 1 and Table 3.

Table 3. Sensitivity analysis: facial expression confidence score.

Metric	Full model (30 features)	Reduced model (29 features)	Δ[a]
AUC-ROC[b]	0.9527	0.9527	+0.0000
Recall (sensitivity)	0.9231	0.9231	+0.0000
F_2-score	0.8955	0.9023	–0.007
SHAP[c] rank correlation (ρ)	—[d]	0.959[e]	—

[a]Δ = full model – reduced model.

[e]P<.001.

Model Comparison

All 7 models were evaluated on the same held-out test set (Table 2). LightGBM and XGBoost produced FP=1 on the test set and were therefore excluded from the primary model selection. Within the FP=0 group, random forest achieved the highest AUC-ROC and was retained as the primary model. The SVM substantially underperformed (AUC-CV=0.8633; test AUC=0.8092; FP=13) and was excluded from further consideration. A gradient boosting surrogate was used for SHAP-based interpretability analysis.

Clinical Threshold Analysis

A threshold sensitivity analysis was performed for the gradient boosting surrogate across 9 decision thresholds (0.25-0.65). Performance remained stable between 0.25 and 0.55 (recall=88%; specificity=96%; FP=1; FN=3), reflecting strong probabilistic separation. Above threshold 0.60, recall drops to 84.6% (FN=4); this range is therefore not recommended. The primary random forest model operates at the Optuna-optimized threshold of 0.48, achieving FP=0 and specificity of 100% (full results in Table 2).

Feature Importance and SHAP Analysis

Feature importance was assessed using SHAP [30] values computed via Tree Explainer on a gradient boosting surrogate model trained on the same 30 features, the same stratified 80/20 split, and the same preprocessing pipeline as the primary random forest classifier (surrogate AUC-ROC=0.9438). This surrogate-based approach was adopted because Tree Explainer yields exact Shapley values for gradient boosting's additive ensemble of shallow trees, whereas application to a random forest requires approximations that degrade under correlated predictors [37,38]. This strategy is consistent with established practice in clinical ML interpretability research [38,39].

Surrogate fidelity was confirmed by a Spearman rank correlation of ρ=0.78 (P<.001) between GBM-SHAP and random forest Gini-impurity rankings, with the 4 most influential features shared across both: attentional bias toward emotional stimuli, visual attention toward joyful facial expressions, visual exploration efficiency, and the proportion of time expressing sadness-related facial expressions. This consistency ensures that the clinical narrative derived from SHAP faithfully reflects the primary model's discriminative logic. It should be noted that the surrogate exhibited FP=1 across all tested thresholds, reflecting stochastic variability inherent to independent model fitting; this does not affect the validity of the SHAP analysis, as both models achieved comparable AUC-ROC (ρ=0.78). SHAP contributions were aggregated by feature group and by facial emotion stimulus category.

Aggregating SHAP contributions by feature category reveals the relative importance of each behavioral domain to the classification decision, as represented in Table 4.

XSL•FO
RenderX

Table 4. Shapley additive explanations (SHAP) weight distribution by feature group.

Feature group	Total absolute SHAP value (%)
Per-emotion features (expression + gaze)	3.6677 (37.1)
Eye-tracking (oculomotor/attention)	3.2362 (32.7)
Aggregated emotion	2.4375 (24.6)
Composite indices (VEI[a]/AII[b]/OCI[c]/ERI[d]/SEI[e])	0.3895 (3.9)
Demographic (age)	0.1641 (1.7)

[a]VEI: Visual Efficiency Index.

[b]AII: Attentional Instability Index.

[c]OCI: Oculomotor Control Index.

[d]ERI: Emotional Reactivity Index.

[e]SEI: Social Exploration Index.

The 3 most informative domains collectively account for 94.4% of total SHAP weight. Per-emotion features (37.1%) capture how children's facial expressions and gaze allocations differ per emotional stimulus, particularly fear (|SHAP|=0.753), sadness (|SHAP|=0.717), and anger expressions (|SHAP|=0.571). Eye-tracking metrics (32.7%) capture oculomotor instability and scanning inefficiency: higher gaze path length, greater fixation duration variability, and elevated interfixation interval variability are all associated with the lower attentional-performance profile. Aggregated emotion indices (24.6%) are dominated by the mean of recognition bias (|SHAP|=1.726), the ratio of fixations toward negative vs positive emotional faces, which is the single most predictive feature in the model.

The results indicate that lower attentional performance prediction derives from converging evidence across emotional face processing, oculomotor control, and cross-emotion behavioral consistency, consistent with theoretical accounts linking attentional difficulties in childhood to lower attentional performance in both executive attention and socioemotional processing (Table 4).

Among the 30 selected features, the subset of per-emotion features, derived specifically from 1 of the 5 emotional face stimuli (happiness, fear, sadness, anger, and surprise), accounts for a cumulative SHAP weight of 3.667, representing 37.1% of the total model importance. The contributions are markedly unequal across emotional categories:

- Happiness (SHAP=1.338, 36.5%): the dominant emotional stimulus. The majority of this effect was driven by the average visual attention directed toward joyful facial expressions (SHAP=1.249), the proportion of fixations directed toward the joyful face. Children with lower attentional performance show an atypical allocation of visual attention to positive emotional faces, a pattern consistent with altered social orienting.
- Fear (SHAP=0.861, 23.5%): the second most informative stimulus, combining sustained fear expression duration (SHAP=0.753) and its variability (SHAP=0.108). Prolonged and variable fear expressions in the lower attentional performance group suggest heightened anxious reactivity and difficulty recovering from negative emotional arousal.
- Sadness (SHAP=0.717, 19.5%): captured entirely by the proportion of time spent expressing sadness-related facial expressions. Elevated sadness expression was associated with the lower attentional-performance profile, potentially reflecting lower task motivation and negative affective responses during sustained attention demands.
- Anger (SHAP=0.703, 19.2%): contributed through expression duration (SHAP=0.571) and gaze allocation toward the angry face (SHAP=0.132). Together, these indicate both prolonged angry expression episodes and an attentional bias toward threat stimuli, a pattern associated with emotional dysregulation in children with lower attentional performance.
- Surprise (SHAP=0.027, 0.7%): the least informative emotional stimulus. The short duration of expressed surprise provides minimal discriminative power, suggesting that surprise stimuli do not elicit substantially differentiated behavioral responses between the 2 groups.

The 3 negative emotional stimuli combined (fear, sadness, and anger) account for 62.2% of the emotional stimulus contribution, underscoring the disproportionate role of negative affect processing in the attentional-functioning classification. Happiness, while positive, ranks first partly because gaze allocation toward a joyful face is a sensitive marker of social attention, a process known to be altered in children with attentional and executive difficulties.

Multimodal Behavioral Profiles Associated With Attentional Functioning

Overview

To move beyond aggregate performance metrics and toward a clinically meaningful characterization of the model's discriminative logic, 2 composite behavioral profiles were constructed. These profiles describe the patterns of oculomotor, attentional, and facial-emotional behavior that systematically differentiate children at high risk of lower attentional performance from those presenting typical attentional development, as identified through SHAP analysis of the gradient boosting surrogate model.

Each dimension reported below is grounded in the feature's mean absolute SHAP value, its contribution to the multivariate classification decision, and independent univariate group

XSL•FO
RenderX

comparisons (independent-samples *t* tests, n=130 per group, 2-tailed), as well as Cohen *d* effect sizes.

Profile A: Neurobehavioral Profile Associated With Lower Attentional Performance

Children with lower attentional performance exhibited a coherent multidimensional behavioral profile characterized by:

- Attentional bias toward negative stimuli and increased gaze allocation to socially salient faces.
- Instability and inefficiency in oculomotor control, reflecting disrupted attentional regulation.
- Diffuse and inflexible emotional expression patterns, combining broader affective range with reduced intensity and slower transitions.

This lower attentional-performance profile emerges from the convergence of these 3 behavioral signatures: a systematic attentional bias toward emotionally salient and threatening stimuli, markedly inconsistent and inefficient oculomotor control, and a pattern of diffuse, emotionally inflexible facial expression. Importantly, no single feature is sufficient to define this profile; rather, it is the combined expression of these dimensions that characterizes the lower attentional-functioning profile.

Profile B: Neurobehavioral Profile Associated With Higher Attentional Performance

Children with higher attentional performance exhibited a distinct and active behavioral profile, rather than simply the absence of high-risk markers. This profile reflects efficient, balanced, and flexible cognitive-emotional processing, characterized by adaptive attention allocation, stable and economical oculomotor control, and clear, dynamic emotional expression. Importantly, the low-risk profile emerges from the convergence of three complementary behavioral signatures: balanced attentional deployment across emotional stimuli, consistent and efficient gaze dynamics, and emotionally expressive yet flexible affect regulation. These characteristics represent positive indicators of attentional health rather than merely the inversion of lower-performing attentional features.

Children in the low-risk group, therefore, displayed a coherent and adaptive behavioral profile characterized by:

- Balanced attentional allocation, avoiding overfocus on emotionally salient or threatening stimuli.
- Stable and efficient oculomotor behavior, reflecting organized and sustained attentional control.
- Clear, expressive, and emotionally flexible responses, indicating effective affect regulation.

Discussion

Principal Findings

This study aimed to identify multimodal behavioral patterns associated with different levels of attentional functioning, integrating neuropsychological, oculomotor, and emotional measures within an ML framework. Consistent with previous eye-tracking studies, which have demonstrated that objective measures of visual attention can capture subtle attentional impairments in children with lower attentional performance beyond traditional behavioral observation [40,41], the current findings suggest that combining these objective markers may enhance the sensitivity of assessment frameworks. Overall, the results supported the proposed hypotheses, though with some nuances in the strength and specificity of the observed effects.

The results indicate that children with lower attentional performance exhibit less efficient, more unstable oculomotor patterns, characterized by increased gaze instability, greater variability in fixation duration, and more fragmented visual exploration, along with a higher frequency of impulsive saccadic movements. These results are consistent with previous literature indicating that lower attentional performance is associated with impaired oculomotor control and reduced visual efficiency [20,22]. From a neurodevelopmental perspective, such patterns may reflect underlying inefficiencies in EFs, particularly inhibitory control and processing speed, which are critical for regulating visual attention and goal-directed behavior [3,6]. This interpretation aligns with theoretical models suggesting that deficits in behavioral inhibition disrupt attentional regulation [24]. These findings are consistent with H1, supporting the expectation that lower attentional performance is associated with less efficient and more unstable oculomotor behavior.

A distinctive methodological contribution of this study is the simultaneous, real-time capture of oculomotor, emotional, and cognitive-behavioral streams within a single platform. Unlike traditional assessments, in which gaze data, emotional responses, and neuropsychological performance are collected separately and analyzed post hoc, the present approach enables direct observation of dynamic cognitive-emotional interactions as they unfold during task performance. This revealed patterns, such as the cooccurrence of gaze instability and heightened expression of fear or anger within the same task. This approach allows us to identify not only whether a child performs poorly, but also precisely when and in what emotional context attentional dysregulation emerges, providing a richer basis for generating hypotheses about future personalized intervention strategies.

Additionally, emotional stimulus was found to play a significant role in modulating attention allocation. Conditions involving anger and fear showed strong discriminative value between groups, suggesting that attentional processes are particularly sensitive to emotionally salient information. Children with lower attentional performance demonstrated altered gaze patterns and heightened emotional reactivity to these stimuli, suggesting that emotional processing may interfere with attentional control.

The findings are consistent with previous research indicating that lower attentional performance is associated with atypical processing of emotional cues, including altered gaze allocation to socially relevant facial features and difficulties in social-emotional perception [27,42,43]. Furthermore, eye-tracking metrics revealed increased fixation pattern variability and altered saccadic latencies, consistent with difficulties in maintaining goal-directed visual attention and in efficient attentional control. Previous studies have shown that such oculomotor alterations are characteristic of children with ADHD and other neurodevelopmental conditions [22,44].

XSL•FO
RenderX

From a broader perspective, the attentional inefficiencies may contribute to cognitive overload and emotional dysregulation, underscoring the close interaction between attentional and affective processes during development. Children with normative attentional performance, by contrast, exhibited more stable fixation patterns, consistent saccadic control, and lower variability across oculomotor indices. These findings are in line with previous eye-tracking studies indicating that normative developmental profiles are characterized by efficient visual attention allocation and a preference for socially relevant stimuli [40,45]. In this context, the results support H2, indicating that emotional stimuli differentially modulate attentional allocation as a function of attentional performance level. The correspondence between our results and the existing literature supports the use of multimodal behavioral markers as promising behavioral indicators of attentional functioning, providing a reference framework against which deviations related to attentional impairments and emotion-related processes can be identified.

Furthermore, the interaction between gaze behavior and emotional expression emerged as a relevant factor in distinguishing attentional profiles. Composite cognitive-emotional indices, such as the Gaze-Emotion Congruence Index and Emotional Reactivity Index, were identified as highly informative features, highlighting the importance of integrated processing across domains. Children with lower attentional performance showed greater variability in both gaze and emotional expression, suggesting less consistent and less coordinated responses. These findings align with theoretical perspectives that emphasize the interdependence of cognitive control and emotional regulation systems during development [42,46]. Rather than reflecting a complete dissociation between domains, the results point to a pattern of dysregulated integration, in which attentional and emotional processes interact in a less stable and less adaptive manner. Similarly, fear-related stimuli elicited attentional disruptions, including prolonged fixations and difficulty disengaging from threatening cues. These patterns are consistent with eye-tracking findings indicating that children exhibiting attentional difficulties display atypical gaze allocation toward fearful faces, accompanied by reduced accuracy in recognizing threat-related emotions [47]. Neurodevelopmental research suggests that atypical amygdala-prefrontal functional dynamics contribute to these effects, reducing top-down modulation and promoting hypervigilance to threat cues [48,49]. Therefore, the findings support H3, suggesting weaker integration between gaze behavior and emotional expression in children with lower attentional performance.

The integration of multimodal behavioral data into a multimodal ML framework suggests potential applications for early screening and for informing future personalized intervention approaches. SHAP analyses allowed identification of the features that most strongly influenced model predictions, offering concrete targets for interventions to improve gaze stability, visuomotor control, and emotion recognition [41,42]. Importantly, it highlights the dynamic interplay between attention, cognition, and emotion, emphasizing the need for integrated intervention strategies that target multiple domains simultaneously.

The study's findings support H1, H2, and H3, highlighting a pattern of oculomotor inefficiency, altered emotional modulation of attention, and reduced integration between cognitive and affective processes in children with lower attentional performance. Nevertheless, it is important to note that these findings reflect behavioral patterns associated with attentional functioning and do not constitute clinical diagnoses.

Finally, this study contributes to the growing body of literature advocating ecologically valid and data-driven approaches to the assessment of neurodevelopmental conditions. By integrating oculomotor behavior, emotional processing, and executive functioning, the present results support a more comprehensive understanding of attentional difficulties during development and highlight the value of multimodal assessment models for early identification and intervention.

Limitations

Despite the promising findings, several limitations warrant consideration. The study was conducted with a relatively small sample size (N=260), which may limit the generalizability of the results and increase the risk of model overfitting, despite nested cross-validation confirming the absence of test-set inflation (ΔAUC=0.0021). The class labels were derived from screening-based cutoff scores (≤7 in the Cancellation task, TMT A, and TMT B) rather than a formal clinical diagnostic gold standard. One feature related to facial expression detection confidence emerged as an influential predictor and showed significant differences between groups. A sensitivity analysis conducted with and without this feature demonstrated that classification performance remained unchanged (ΔAUC=0.000 and Δrecall=0.000) and SHAP-based feature rankings were highly stable (Spearman ρ=0.959; P<.001; 8/10 top features identical), indicating that the model's predictive behavior does not depend on this feature. Nevertheless, a contribution from recording-quality factors (eg, occlusion, lighting, or camera angle) cannot be completely excluded. Consequently, the proposed model should be interpreted as a decision-support or screening tool rather than a definitive diagnostic system. Although the model demonstrated strong internal validation performance through stratified cross-validation and holdout testing, external validation across independent cohorts, larger populations, and multicenter clinical settings remains necessary to further establish its robustness, reproducibility, and real-world clinical applicability. The protocol included tasks that were conducted in semicontrolled environments. Fully naturalistic settings may yield additional insights. Furthermore, medication use was not controlled for and may have influenced attentional and emotional performance, yet the observed patterns remained robust across participants. Cultural and linguistic factors may also influence emotion recognition and attentional patterns, suggesting the need for cross-cultural validation.

Future research should explore longitudinal designs to track developmental trajectories and evaluate the long-term effects of interventions on attentional and emotional regulation, particularly regarding their applications and potential for personalized intervention plans, thereby reinforcing the clinical

XSL•FO
RenderX

relevance of combining behavioral, emotional, and neurocognitive indices.

Conclusion

The findings indicate that children with lower attentional performance exhibit a complex interplay of attentional instability, oculomotor variability, and heightened emotional reactivity, particularly in response to anger and fear stimuli. These patterns support the proposed hypotheses and suggest that attentional functioning is dynamically shaped by interactions between cognitive and emotional processes. The results highlight the multidimensional nature of attentional functioning, extending beyond isolated cognitive mechanisms to include integrated emotional dynamics. Notably, variability across oculomotor and emotional domains suggests that attentional performance is better understood as emerging from interactions between these systems rather than as discrete abilities.

From a clinical and educational perspective, the multimodal approach, grounded in real-time data capture and post hoc interpretable ML analysis, yields objective, scalable indicators of attentional and emotional functioning, providing a basis for generating hypotheses about future personalized intervention strategies.

This study provides preliminary evidence supporting the use of a multimodal screening approach for differentiating children with varying levels of attentional performance. By integrating eye-tracking, facial emotion recognition, and neuropsychological measures within a single platform, the random forest model achieved high predictive accuracy and robust generalization, as confirmed by nested cross-validation, highlighting its potential as a complementary and ecologically valid assessment tool. The ability to capture oculomotor and emotional data simultaneously within a single session supports the feasibility of a practical, time-efficient assessment approach, though further validation in pediatric and educational settings is needed. Additionally, the use of interpretable ML techniques (eg, SHAP) enhances model transparency and applicability across research and applied contexts. Overall, integrating multimodal behavioral data within an explainable AI framework represents a promising direction for advancing assessment practices regarding attentional functioning across development.

Abstract

Background: Although childhood behavior problems are common, and strong evidence-based interventions exist to address these challenges, many families struggle to access care and remain in treatment long enough to see results. The Support and Advocacy through Providing Parents Helpful Interventions, Resources, and Education (SAPPHIRE) program was developed to address barriers to accessing care for disruptive behaviors in young children.

Objective: This quality improvement program assessed the feasibility of SAPPHIRE, a primary care–based intervention delivered via telephone by trained nurses to caregivers of young children (n=36, ages 1 - 6 y) who exhibit disruptive behaviors.

Methods: The feasibility and acceptability of the SAPPHIRE program were assessed during a 3-month quality improvement study.

Results: Of 36 participants, 25 (69%) completed the SAPPHIRE program. Over the course of 3 months, the number of nurse calls with completers ranged from 1 to 15, with a mean of 5.3 (SD 3.4) calls. Overall, nurses spent an average of 120.9 (SD 99.2, range 15 - 380) minutes on the phone with each caregiver across the 3-month pilot period. Caregivers and nurses rated the program as acceptable across all metrics. For nurses, strengths of SAPPHIRE included the continuity of care with one family, while barriers included time constraints. Comparison of preintervention and postintervention caregiver ratings on measures of disruptive behaviors showed a moderate to negligible effect on reported behavior problems depending on the age of the child (children <4 y: d=0.55 and children 4 - 6 y: d=0.18). Caregiver-rated parenting self-competence increased over the course of the SAPPHIRE intervention, approaching a large effect (d=0.75).

Conclusions: Findings suggest that SAPPHIRE is a feasible and acceptable treatment for caregivers of young children with disruptive behaviors and shows promise for increasing parenting self-competence, which is a hypothesized moderator of future behavior problems. These preliminary data support the need for more rigorous empirical evaluation of the SAPPHIRE program.

Introduction

Many young children struggle with disruptive behaviors (eg, physical and/or verbal aggression, defiance, etc) that impact their daily functioning at home and in school or daycare settings [1,2]. Prevalence rates of full-threshold disruptive behavior disorders in young children vary, but a recent meta-analysis estimates that as many as 4.9% of children between the ages of 1 and 7 years may meet the criteria for oppositional defiant disorder [2]. Although a spectrum of disruptive behaviors is considered normative in the developmental trajectory, children exhibiting these patterns of behavior—and their caregivers—can still benefit from interventions aimed at both decreasing disruptive behaviors and increasing family and caregiver functioning [3,4].

Even more, early childhood interventions targeting disruptive behaviors have been shown to decrease symptoms of early behavioral issues, bolster caregiver resiliency, and decrease the likelihood of later behavioral health diagnoses for their children [5,6]. Increasing accessibility and utilization of behavioral health

XSL•FO
RenderX

treatment is particularly important, as studies support the efficacy of early childhood intervention in preventing later behavioral problems, with data suggesting that early emerging problem behavior in young children is malleable through family and caregiver-based interventions [7-9]. Data show that caregivers want opportunities to learn why their children are exhibiting disruptive behaviors and to develop skills to effectively respond to these patterns [10].

There are numerous effective interventions that target disruptive behavior in younger children; however, engagement in treatment may be limited due to a shortage of behavioral health providers trained in these modalities, as well as other accessibility challenges such as finding childcare, transportation, and cost [5,11-13]. Gold-standard interventions, such as Parent-Child Interaction Therapy [7], or Parent Management Training [14] are time- and resource-intensive, and mental health services are not always readily available in easy-to-access healthcare settings [11-13]. These interventions are thus characterized by access disparities, particularly across race and ethnicity [11,13]. Well-established interventions, such as Applied Behavioral Analysis, which are often offered in the home for families of children with behavioral concerns secondary to diagnoses including autism spectrum disorder, address some of these access issues by offering intervention in the family's home environment [15]. These interventions, however, are costly and similarly difficult to access, which is why they are typically used for high rates of symptom severity [15]. Studies have shown significant rates of caregivers of children with disruptive behavior problems being lost to care when referred to behavioral health providers, both in community and primary care settings [13,16]. Accordingly, there is a substantial need for innovative care models that address barriers to access and engagement in treatment aimed at early intervention for young children with disruptive behavior problems.

One potential solution to improve access disparities is to integrate pediatric behavioral health services into the primary care setting [17]. Most youth have access to and visit primary care settings at least annually, so integrating behavioral health services into these clinics has the potential to reach a broad range of patients early in their symptom trajectory [18]. This approach has particular promise for addressing concerns about disruptive behavior, as studies suggest that a first step for many caregivers of children with disruptive behavior is to consult with their primary care provider [19]. As such, positioning low-impact interventions for disruptive behaviors at the point of primary care may increase families' ability to follow through on receiving care [17,18,20-23].

Primary care–based behavioral health interventions have thus far been shown to be effective in decreasing and/or preventing depression, anxiety, and behavior issues in children and adolescents [20]. However, these approaches are not without their limitations regarding accessibility [22,23]. For one, most established primary care–based interventions for behavior problems exclude children younger than 5 years [24], precluding the use of those models as an early intervention. In addition, most models rely heavily on face-to-face, in-person care and the availability of embedded behavioral health providers to deliver the intervention. There is a relative dearth of literature examining alternative methods of behavioral health integration in primary care, such as using providers who may have more availability and are already staples of the primary care setting, such as nurses, or using alternative modes of treatment delivery, such as phone or video encounters, which reduce the need for in-person visits.

To our knowledge, only one group has developed a program designed to address this gap: the Strongest Families Smart Website (SFSW). This program, which was developed in Canada and further evaluated in Finland, includes 11 weekly web-based modules and accompanying telephone calls delivered by trained coaches, including nurses and individuals with public health backgrounds [25]. SFSW was found to have good acceptability and feasibility for parents of 4-year-olds with disruptive behavioral problems in Finland [26], and it demonstrated a significant impact on externalizing and internalizing behaviors that persisted after a 2-year follow-up period [26,27]. The promising results of this program lend support to the potential of phone- and web-based delivery of behavioral management strategies and suggest that nurses can be trained to effectively deliver coaching to help supplement skills training in this area. It should be noted, though, that the SFSW program remained a relatively sizable time commitment (an average of 451 min on web-based content and 418 min on calls) [26] and required sufficient staffing to deliver the coaching calls, which averaged 38 minutes per call. This may not be feasible for all health systems and potentially might be too much of a commitment for use as an indicated prevention or early intervention program for families of younger children and/or children with subclinical disruptive behavior concerns.

To address some of these gaps, the Support and Advocacy through Providing Parents Helpful Interventions, Resources & Education (SAPPHIRE) was developed—a primary care–based intervention that is delivered via brief telephone sessions with trained nurses. The program is designed to be used as part of a stepped care model for caregivers of young children (1 - 6 y) who have disruptive behaviors that may place them at risk for disruptive behavior disorders in the future. SAPPHIRE uses well-established, evidence-based principles from behavioral parent training [14] and was designed to increase accessibility and engagement through innovations such as the phone-based, nurse-delivered format.

The primary aim of this quality improvement study was to evaluate the feasibility and acceptability outcomes of the SAPPHIRE treatment, including participant retention, as well as nurse and caregiver satisfaction. A secondary aim of this study was to examine the impact that the SAPPHIRE intervention had on parenting self-efficacy over the 3-month intervention period, as parenting self-efficacy has precedent as serving as a proximal risk factor or moderator for the severity of behavioral problems in young children [28]. It was hypothesized that there would be minimal immediate changes to child behavior during the 3-month treatment period due to SAPPHIRE being a brief, pilot intervention; however, improvement in parenting self-efficacy was expected.

Methods

Ethical Considerations

We assessed the feasibility and acceptability of SAPPHIRE. The Mayo Clinic Institutional Review Board reviewed this study and determined it should be designated as quality improvement and did not require further approval from the institutional review board or other ethics board. As this study was designated as quality improvement, no informed consent or assent was obtained; however, institutional guidelines for human subjects protection for quality improvement projects were followed at all times. No compensation was provided to participants.

Sample, Setting, and Recruitment

Participants were recruited through referrals from pediatric and family medicine providers, including physicians, nurse practitioners, and physician assistants, within the participating primary care practice. All referring providers practiced in the same primary care practice associated with a tertiary medical center located in a small city in the Midwest United States. Eligible participants were parents or guardians of children aged 1 to 6 years who had concerns about their child's behavior. Families already receiving treatment for disruptive behavior problems via a specialty service (eg, psychology, occupational therapy, sleep medicine, etc) were excluded. Aside from these exclusion criteria, providers offered the SAPPHIRE program to all eligible families presenting for a primary care visit between August 1, 2018, and July 31, 2021, with expressed concerns about their child's behavior.

Initial evaluations were completed in-person or, after the onset of the COVID-19 pandemic, when the clinic gained the capacity for video visits, via video by a licensed clinical social worker embedded in the primary care practice. During this evaluation, the social worker completed a diagnostic assessment and provided psychoeducation on behavioral parent training principles [14]. The social worker was responsible for assessing the severity of disruptive behaviors, determining if there was an immediate need for a higher level of care, and evaluating the family's ability and interest in participating in SAPPHIRE. The SAPPHIRE nurse then followed up with an initial phone call within approximately one week. Enrollment was contingent upon nurse availability. Given the high rates of staffing shortages due to both situational circumstances (eg, medical and parental leaves) and the impact of the COVID-19 pandemic, families were enrolled on a rolling basis, based on staff availability. Nursing staff typically followed 1 family at a time, with a maximum caseload of 2 concurrent families.

Intervention

SAPPHIRE is a phone-based program in which pediatric primary care nurses provide support and coaching for families implementing behavioral parent training-based strategies. SAPPHIRE was developed in 2018, before the primary care clinic in question had the capacity to deliver video-based care. As such, the telephone was selected as the delivery method to be more convenient for families, as opposed to an in-person visit, which was the only other modality available at that time. The intervention itself was developed using evidence-based parenting principles [14], by board-certified child and adolescent psychologists and licensed clinical social workers with expertise in behavioral interventions for children. Feedback from experts in the fields of child psychology and primary care nursing was obtained and incorporated into the development of the program. During the 3-month intervention period, phone calls took place weekly or biweekly, based on caregiver schedules and nursing clinical judgment. Calls were supplemented by portal messages sent by nurses to summarize the content of each call, as well as to check in with the family during any gaps in contact. Caregivers could also reach out to their nurse-provider via portal or phone between scheduled sessions as needed.

At their intake appointment, families established 2 to 3 behavioral goals for their SAPPHIRE participation. These goals were based on evidence-based parenting principles, including increasing praise and special time, setting clear and consistent expectations, using selective attention, and implementing reinforcement schedules [29]. At the start of each nurse call, these treatment goals were reviewed, progress was measured, and barriers to success were problem-solved. If these initial goals were met, new goals were established with the SAPPHIRE nurse, with as-needed behind-the-scenes consultation with the social worker. Families did not meet with the social worker again during the SAPPHIRE program. When applicable, nurses sent patient education materials or community resources to caregivers following the calls. Nurses also provided support for caregivers by using strategies such as normalizing developmentally appropriate child behaviors and caregivers' emotional responses to these behaviors, as well as providing education about typical childhood development.

Training and Supervision

Six registered nurses with experience working in a pediatric primary care setting (experience ranged from 10 to 30 y) delivered the SAPPHIRE intervention. One nurse had experience working on a child and adolescent psychiatric inpatient unit for 3 years. The other nurses did not have a background in behavioral health. Training was conducted by a board-certified child and adolescent psychologist and a licensed clinical social worker with a specialty in child behavior problems. Training included: (1) readings on behavioral parent training and behavior change principles; (2) participation in 2-hour-long interactive sessions on behavioral parent training strategies and strategies for supporting caregivers, including active listening, normalizing behaviors, promoting self-care, and motivational interviewing; and (3) shadowing social workers for a minimum of 2 hours to observe behavioral parent training therapy sessions.

In addition, nurses participated in monthly hour-long group case consultations with a clinical psychologist and/or a licensed clinical social worker. Topics included case consultation, assessment of treatment adherence and fidelity, and review of SAPPHIRE skills. During this time, nurses reviewed cases and worked collaboratively with the psychologist and social worker to evaluate patients' progress and re-evaluate the appropriateness of treatment goals and the SAPPHIRE program as a whole for the patients' current symptoms. Additionally, the psychologist and social worker were available for as-needed individual case consultations between meetings.

Measures

At baseline and at the end of treatment, caregivers completed one of two questionnaires assessing their concerns about their child. For older children (ages 4 - 6 y), caregivers completed the Pediatric Symptom Checklist-17 (PSC-17) [30], a 17-item caregiver-report measure used to assess emotional and behavioral problems in children aged 4 years and older. The PSC-17 has been well-validated and contains 3 subscales—attention, internalizing, and externalizing—as well as a total score [31]. Caregivers of children younger than 4 years completed the Preschool Pediatric Symptom Checklist (PPSC) [32], an 18-item emotional and behavioral screening tool used for the early detection of emotional and behavioral problems in infants and preschoolers. This tool is widely used in primary care settings and contains 4 subscales: externalizing, internalizing, attention problems, and parenting challenges [32]. Additionally, at baseline and at the end of treatment, caregivers completed the Parenting Sense of Competence Scale [33], a 17-item measure that assesses self-efficacy in parenting.

Data Collection

Caregivers completed all measures on paper. Families who were scheduled to be on-site for another medical appointment completed the surveys at that time. No families made a separate trip to the clinic to complete the measures. For families who were not planning to be on-site, paper measures were either mailed to them along with a self-addressed stamped envelope or sent as an attachment in their patient portal. Finally, an option to complete the surveys over the phone with a nurse was also offered. If caregivers selected this option, in order to minimize response bias, the nurse who assisted them with their forms was not the same nurse who delivered their SAPPHIRE intervention. Nurses worked with caregivers to determine which method of survey delivery was most convenient for the family.

Data Analysis

Descriptive statistics were calculated to examine retention, patient or family characteristics, and treatment characteristics. In addition, Cohen *d* calculation for *t* tests was used to obtain the effect sizes of significant differences identified and was interpreted according to the following guidelines: 0.02=small effect, 0.05=moderate effect, 0.8=large effect [34].

Results

Participant Characteristics

In total, parents or guardians of 36 children (mean age=4.32, range: 1.42-6.92 y) were enrolled and participated in at least 1 nurse call as part of SAPPHIRE. The sample included 35 (97%) biological mothers and 1 (3%) biological father out of 36 caregivers. Children included 22 (61%) male-identifying children and 14 (39%) female-identifying children out of 35 children. The vast majority were White (34/36, 94%). Most had private insurance (25/36, 69%), followed by Medicaid (9/36, 25%) and Tricare (2/36, 6%). Children were given a range of *International Classification of Diseases, Tenth Revision* diagnoses, including problem behavioral child (18/36, 50%), any adjustment disorder (modifiers included with disturbed conduct, with mixed emotion and conduct, and undefined) (6/26, 17%), attention deficit/hyperactivity disorder or deficit of attention or concentration (3/36, 8%), developmental delay—speech (2/36, 6%), anxiety (1/36, 3%), and disruptive behavior disorder (1/36, 3%). Five out of 36 (14%) patients did not receive a diagnosis. See Table 1 for participant characteristics.

At baseline, 6 caregivers completed the PPSC with a mean score of 13.67 (SD 3.8). Scoring conventions suggest that scores higher than 9 on the PPSC indicate a child is “at risk” and warrant further intervention. Seventeen caregivers completed the PSC-17 for their children, with a mean global score at baseline of 12.94 (SD 5.8), which was slightly below the clinical cutoff of 15. Finally, 24 caregivers rated their parenting self-competence on the Parenting Sense of Competence Scale, with a mean baseline score of 68 (SD 9.6).

Primary diagnosis, n (%)	
Problem behavioral child	18 (50)
Adjustment disorder (with disturbed contact, with mixed emotion and conduct, undefined)	6 (17)
None	5 (14)
ADHD or deficit of attention or concentration	3 (8)
Developmental delay—speech	2 (6)
Anxiety	1 (3)
Disruptive behavior disorder	1 (3)

Feasibility

Twenty-five out of 36 (69%) families completed the SAPPHIRE pilot program. Treatment completers were defined as families who successfully finished 3 months of the SAPPHIRE intervention or achieved all treatment goals before the 3-month period. Drop-outs were families who did not return for scheduled nurse calls and were lost to follow-up before achieving all treatment goals. Four out of 36 (11%) families were referred to a higher level of care (eg, Parent-Child Interaction Therapy or another more intensive behavioral therapy) before completing the program, and 7 out of 36 (19%) families dropped out without completing treatment after an average of 2.7 nurse calls, with a mode of 1 nurse call. One outlier family received 10 nurse calls before dropping out. Once they were removed from the analyses, the average number of nurse calls for dropouts was 1.5.

Over the course of 3 months, the number of nurse calls with completers ranged from 1 to 15, with a mean of 5.3 (SD 3.4) calls. In total, caregivers from this group had an average of 1.4 (SD 1.7) no-shows for scheduled calls. The mean number of portal messages sent was 2.2 (SD 2.9; range: 0 - 14). Overall, nurses spent an average of 120.9 (SD 99.2, range: 15 - 380) minutes on the phone with each caregiver across the 3-month pilot period. Table 2 describes SAPPHIRE usage data.

Table . Usage data from families enrolled in the Support and Advocacy through Providing Parents Helpful Interventions, Resources, and Education (SAPPHIRE) program (N=36).

	Mean (SD)	Range
Number of sessions	4.4 (3.4)	1 - 15
Number of portal messages	2.2 (2.9)	0 - 14
Number of no-shows	1.4 (1.7)	0 - 8
Total time in intervention (min)	120.9 (99.2)	15 - 380

Acceptability

Caregivers rated the amount of time they spent participating in SAPPHIRE as “just right” and felt the phone-based format was “very convenient” (M=4.78/5). Overall, they thought the program was “very helpful” (M=4.61/5) and rated it as “very good” (M=4.78/5). Caregivers reported that, if they were to go back and do things over, they would be “very likely” (M=3.22/4) to participate in the program again and that they would “absolutely” recommend the program to another family of a

XSL•FO
RenderX

young child with behavior concerns (M=3.5/4). See Table 3 for caregiver acceptability data.

Table . Caregiver feedback on the acceptability of the Support and Advocacy through Providing Parents Helpful Interventions, Resources, and Education (SAPPHIRE) program.

Questions	Mean (range)
How serious do you currently consider your child's behavior problem (0=not at all; 10=very serious, inpatient treatment necessary)?	3.5 (0 - 8)
How strongly did you influence your child's behavior during your time in the SAPPHIRE program (1=not at all; 5=very strong)?	3.5 (1-5)
How confident do you feel that you will be able to manage your child's behavior in the future (1=not at all confident; 5=very confident)?	3.72 (2-5)
How time-consuming did you find participating in SAPPHIRE (0=far too time-consuming; 3=wish there was more time)?	2 (1-3)
How convenient was the phone-based care coordination (0=inadequate; 5=very)?	4.78 (4-5)
How helpful was SAPPHIRE (0=very unhelpful; 5=very helpful)?	4.61 (3-5)
How would you rate the program as a whole (0=inadequate; 5=very good)?	4.78 (4-5)
If you were to go back in time, would you participate in this program again (0=no way; 4=absolutely)?	3.2 (0 - 4)
Would you recommend the program to another family whose young child has issues with behavior (0=no way; 4=absolutely)?	3.5 (2-4)

Caregivers also provided qualitative feedback on program acceptability. Caregivers felt that both the concrete suggestions for implementing and maintaining behavior plans, as well as the personalized support and reassurance, were the most helpful aspects of the program. Caregivers also commented on how the regular follow-up and accountability were very useful and how much they appreciated the continuity of care in meeting with the same nurse for every call.

The majority of nurses reported they were "satisfied" with being a part of the program (M=4/5), and half felt it increased their job satisfaction. The other half reported that their participation in the program had no impact on their job satisfaction. Nurses largely felt they had adequate training to deliver the interventions (M=2.5/3), and all felt they had adequate support through as-needed consultation with specialists and case consultation meetings. When asked what they liked most about the program, nurses reported finding it rewarding to be able to follow families over time and having continuity of care. They reported feeling like they were helping families and making a difference. One nurse stated that she particularly enjoyed "being able to help parents with their concerns. When I was able to get a hold of parents, providing some specific things to try and providing reassurance was rewarding."

Nurses also described challenges with the program, including finding time to make the calls and focus on their cases amidst their other job responsibilities. For example, one nurse noted that she felt there was "not enough time to focus on multiple (SAPPHIRE) patients due to other job responsibilities." They provided feedback that some of the processes around enrollment and data collection were time-consuming, and they discussed the difficulties of playing "phone tag" when families were unavailable during scheduled calls. See Table 4 for nurse acceptability data.

XSL•FO
RenderX

Table . Nurse feedback on the acceptability of the Support and Advocacy through Providing Parents Helpful Interventions, Resources, and Education (SAPPHIRE) program.

Questions	Mean (range)
Please rate your satisfaction in being a part of the SAPPHIRE Program. (1=very unsatisfied; 5=very satisfied).	4 (3-5)
How did participating in the SAPPHIRE Pilot impact your job satisfaction? (1=decrease job satisfaction; 3=increase job satisfaction)?	2.5 (2-3)
Did you feel you had adequate training in SAPPHIRE strategies prior to seeing patients? (1=no; 3=yes)?	2.5 (1-3)
Did you feel you had adequate support from specialists (eg, social worker and/or psychologist) for as-needed case consultation during the intervention? (1=no; 3=yes)?	3 (3-3)
Were the amount of case consultation meetings (1=too few, 2=just right; 3=too many)?	2 (2-2)
What did you like most about participating in the SAPPHIRE pilot?	• I get to use my previous psychology experience and work toward my license. • I enjoy getting to know these families and helping them and their children succeed. • Relating to parents, as I have children the same age. • Continuity of care. • Being able to help parents with their concerns. When I was able to reach parents, providing some specific things to try and providing reassurance was rewarding. Reinforcing the tools that social work had discussed with parents in the office. • Felt like I was helping parents and patients and making a difference.
What did you like least about participating in the SAPPHIRE pilot?	• Not enough time to focus on multiple patients due to other job responsibilities. • I would like the referral process to be better streamlined. • Times when there was no warm handoff; inconsistency with enrolling patients (the email system did not work) • Not my area of clinical knowledge, and I did not like the work • When unable to reach parents, even when a date and time were set for a phone visit. • Finding time to do it and playing “phone tag” with parents. • Finding time to complete phone calls and calling families to complete the long surveys.

Preliminary Outcomes

At the end of treatment, caregivers stated that they felt they had a “quite strong” to “strong” influence on their child’s behavior during the course of the program (M=3.5/5) and felt “confident” that they would be able to manage their child’s behavior in the future (M=3.72/5). They rated their child’s current behavior problem as “slightly serious (no intervention necessary)” (M=3.5/10).

Comparison of preintervention and postintervention caregiver ratings on both the PPSC and PSC-17 showed decreases in reported behavior problems. The effect size for the decrease in behavior problems among younger patients who were rated with the PPSC (n=8) exceeded Cohen’s convention for a moderate effect (d=0.55). For the sample of older children (n=7), whose behavior was rated using the PSC-17, there was a negligible effect (d=0.18). Similarly, caregiver-rated parenting self-competence increased over the course of the SAPPHIRE intervention. The effect size for the increase in parenting self-efficacy approached a large effect (d=0.75). See Table 5 for preliminary outcomes.

XSL•FO
RenderX

Table . Preliminary outcome data for patients completing the Support and Advocacy through Providing Parents Helpful Interventions, Resources, and Education (SAPPHIRE) program.

Measures	Baseline		End of treatment		Effect size
	Mean (SD)	n	Mean (SD)	n	
Preschool Pediatric Symptom Checklist (PPSC)	13.67 (3.8)	6	10.38 (7.5)	8	0.55
Pediatric Symptom Checklist-17 (PSC-17) total score	12.94 (5.8)	17	11.86 (6.1)	7	0.18
Parenting Sense of Competence Scale (PSOC)	68 (9.6)	24	75.5 (10.4)	16	0.75

Discussion

Principal Findings

Findings suggest that the SAPPHIRE program is a feasible intervention for caregivers of young children with disruptive behaviors. Overall, 69% (25/36) of caregivers completed the program, which compares favorably to the estimated 49% reported retention rate in larger studies of conventional disruptive behavior interventions [11] and is slightly less favorable than the 75% to 77.6% retention rate of the Canadian and Finnish implementations of the web- and phone-based SFSW program [25,26]. It is unclear whether differences in retention were due to characteristics of the program, cultural differences, or possibly differences in assessment periods (eg, part of the SAPPHIRE quality improvement study overlapped with the COVID-19 pandemic). Future evaluation of this is needed to clarify and address barriers to retention in the SAPPHIRE program, as well as to establish the effectiveness of the intervention in a larger sample.

SAPPHIRE required relatively few resources compared to other disruptive behavior programs, as nurses spent an average total of slightly more than 2 hours on calls with a family. This compared favorably with the approximately 7 hours of phone coaching included in the SFSW program [25,26], though it may have implications for retention that should be explored. Results also suggest that both nurses and participating caregivers found SAPPHIRE acceptable. Caregiver feedback reflects that aspects of the program that were particularly well-received included the regular follow-up, continuity of care, and focus on concrete interventions. Nursing staff also reported good satisfaction with the program, though time for implementation was cited as one of the barriers that might impact future dissemination in primary care settings.

The effect of SAPPHIRE on disruptive behavior was moderate for younger children and negligible, approaching small, for older children. These differences in effect sizes should be interpreted with caution, given the fact that younger and older children were evaluated using distinct measures with different scoring conventions and clinical cutoffs. However, these findings align with the literature, which suggests that younger children are typically more responsive to behavioral interventions [35]. Given that the program was implemented over the course of 3 months, which is likely too brief a time period to have a substantial impact on behavioral patterns, we would not necessarily expect to see large effects on behavior. This may explain why younger children whose parents completed the PPSC screener continued to score slightly above the “at-risk” cutoff of 9 at the end of treatment and why the intervention had a negligible-sized effect on the PSC-17 total score. The 3-month study period was chosen based on quality improvement pilot study parameters rather than clinical considerations. Caregivers expressed some dissatisfaction with the brevity of the program, though feedback also suggests that weekly phone calls may not always be necessary and that it may be possible to decrease the frequency of contact as the program progresses. Future iterations of SAPPHIRE would likely benefit from offering families the option to enroll on a flexible call schedule for longer periods of time, as needed.

It is also possible that effects on behavior were not observed in older children whose symptoms were measured by the PSC-17 because baseline scores for this group were only somewhat elevated and did not exceed clinical cutoffs. As SAPPHIRE was developed as an early intervention or indicated prevention option for children who have not yet developed significant behavior problems that warrant a higher level of intervention, it is important to note that even small decreases in reported behavioral concerns are potentially clinically significant. These results suggest that there is merit in further evaluating SAPPHIRE’s effectiveness and that a longer follow-up assessment period is needed to determine whether the intervention prevents the onset of more serious disruptive behaviors in the future. Though we might not expect major changes in child behaviors after the 3-month SAPPHIRE pilot, we would expect to see larger effects on proximal risk factors, such as caregiver self-competence. As such, the fact that the intervention approached a large effect on this variable (d=0.75) is promising, as are caregiver self-reports of increased confidence in their ability to positively influence their child’s behavior moving forward.

Overall, findings support the feasibility and acceptability of the SAPPHIRE program, and preliminary outcome measurements suggest it may positively impact parenting self-competence. It is possible that, as caregivers attested, the accountability and regular check-ins made possible by the phone-based format of SAPPHIRE helped caregivers apply behavioral parenting strategies consistently and allowed for real-time adjustments to

XSL•FO
RenderX

behavior plans and treatment goals, which increased the likelihood of caregiver follow-through. Patient retention and compliance are major challenges of established, highly effective, evidence-based behavioral interventions. The SAPPHIRE format of nurse-led, phone-based coaching calls may potentially avoid some of the common barriers to accessing and remaining in traditional behavior therapies, including mitigating the difficulties inherent in coordinating in-person sessions while simultaneously trying to parent a young child with challenging behaviors.

There were important lessons learned that should be taken into account when considering the feasibility of this program moving forward. Notably, the field of nursing continues to be characterized by high demand, high turnover, and inadequate staffing models. We found this to be true with SAPPHIRE, as we were often delayed in enrolling patients due to nursing staffing shortages. At several points in the program, new cohorts of nurses had to be trained to provide the care. Though training was efficient and SAPPHIRE itself took a relatively brief amount of time, it still is an additional demand on the already overburdened primary care nurse's schedule. Nurses noted that the time burden of the intervention was still a limiting factor. As such, future iterations of the intervention would benefit from a stakeholder-engaged redesign, in which primary care nursing, nurse administrators, and caregivers are involved in brainstorming ways to further streamline and minimize burdens inherent in finding time for phone calls, playing phone tag, etc.

Limitations

This quality improvement study has several limitations, most notably that no conclusions about program effectiveness can be drawn from this study design, given the small sample. Interpretation of these results must also account for the homogeneous sample, particularly with regard to race and ethnicity, and the fact that the feasibility and acceptability of this study are limited by the brief, 3-month intervention period. In addition, the study time period was characterized by nurse staffing shortages which, while typical for a primary care setting, particularly during the time period that included the onset of the COVID-19 pandemic, prolonged the study enrollment period. This may have led to some time-modified confounding factors that impacted our findings. Patient characteristics and caregiver availability to participate in SAPPHIRE in the last year of this study may have been impacted by the dramatic demands placed on families by the COVID-19 pandemic. Because of this, all findings should be interpreted as preliminary, and the need for additional systematic evaluation of this program cannot be overstated. Even with limitations, however, this study effectively highlights the potential benefit of nurse-led interventions in the primary care setting.

Conclusion

In sum, due to robust support for behavioral parenting programs in improving childhood behavior problems, and despite considerable issues with access and retention for these interventions, the SAPPHIRE treatment model has potential for filling a much-needed treatment-access gap as an early intervention or indicated prevention program for first developing or subclinical behavior problems in young children. Our findings suggest that SAPPHIRE is feasible and acceptable for caregivers of young children and shows promise for increasing parenting self-competence and improving child behavior problems. Although these data are preliminary, they provide support for more rigorous empirical evaluation to examine whether SAPPHIRE is an effective treatment option for this population.

Abstract

Background: In Catalonia, Spain, pediatric primary care is undergoing restructuring, including greater integration of information and communication technologies. The adoption of digital health solutions has increased notably since the COVID-19 pandemic. In areas with limited availability of health care professionals, digital tools are a key strategy for facilitating access to services and ensuring continuity of care.

Objective: This study aimed to evaluate the feasibility, diagnostic agreement, and satisfaction of users and professionals of an acute pediatric video consultation model, referred to as video interconsultation, that includes a synchronous remote physical examination and takes place between health care professionals.

Methods: This was a 20-month prospective within-patient diagnostic accuracy study including 200 children (aged 0 - 14 y) with acute conditions in rural primary care in Catalonia. A secure, closed, real-time, web-based, clinician-assisted video consultation platform enabled remote pediatric assessment—visual examination, audio auscultation via a digital stethoscope, and caregiver-reported symptoms—with a pediatrician remotely guiding a nurse physically present with the child. The intervention was compared, in all cases, with a standard in-person pediatric assessment as the reference standard. Outcomes were feasibility, diagnostic accuracy, and user and professional satisfaction. The platform was developed based on telemedicine usability and clinical safety principles.

Results: Of the 200 children enrolled, remote video consultations were successfully completed in 64.5% (129/200) of cases. Diagnostic agreement with in-person assessment was 78.2% (129/165). Overall mean diagnostic accuracy across all diagnoses was 0.99 (95% CI 0.98 - 1.00), with a mean specificity of 0.99 (95% CI 0.98 - 1.00) and a mean sensitivity of 0.90 (95% CI 0.84 - 0.95), varying by condition, with lower performance for pathologies requiring detailed physical examination. Overall, 95% (190/200) of users and 74% (148/200) of professionals reported a positive experience.

Conclusions: The proposed pediatric video consultation model was feasible, accurate, and well accepted for managing a substantial proportion of acute pediatric conditions in primary care. Its implementation could improve access to medical care in

XSL•FO
RenderX

rural areas and help reduce health care disparities. Further research is needed to support scalability and implementation in routine clinical practice.

Introduction

Background

In Catalonia, children and adolescents represent nearly 20% of the total population. These life stages are critical for development and have specific health needs and challenges. Health interventions during childhood and adolescence have both short- and long-term effects on adult health. Therefore, prevention, health promotion, and equitable access to high-quality pediatric care are essential priorities for the health system [1]. Ensuring appropriate care requires access to a pediatric referral team composed of pediatricians and specialized nurses [2].

When primary care teams include professionals with formal pediatric training, clinical practice becomes more efficient and better aligned with children's needs. Appropriate prescribing improves (particularly of antibiotics), vaccination coverage increases, and unnecessary diagnostic tests and specialist referrals decrease [3]. Similarly, pediatric-trained nurses play a key role in primary care by promoting child health within the community and schools, supporting the management of pediatric demand, and contributing to improved overall quality of care [4].

However, many regions, particularly rural and underserved areas, face a shortage of pediatric specialists, which challenges the continuity and quality of pediatric health care by limiting timely access to diagnosis and treatment. According to the Catalan Pediatrics Society, all primary care pediatric positions in Catalonia are currently filled; however, more than one-third are occupied by general practitioners who, although not pediatric specialists, provide pediatric care in primary care settings [5]. This proportion has increased in recent years, and the geographic distribution of pediatric providers remains uneven, making recruitment especially difficult in rural areas [6]. Similar patterns have been reported in other European countries and in the United States [7,8].

In this context, digital health tools have emerged as promising strategies to support primary care teams, improve access to pediatric expertise, and reduce disparities between urban and rural populations.

In Catalonia, the primary care system already incorporates information and communication technologies to enhance communication between patients and health care professionals, including *eConsulta*—an asynchronous teleconsultation platform—complementing telephone consultations [9]. The use of video consultations, however, remains limited despite a temporary increase during the COVID-19 pandemic. Although still rarely used in routine primary care, this experience has prompted renewed interest in exploring their potential applications in daily clinical practice [10].

Simple digital devices can now be integrated into video consultations to enable remote physical examinations using a digital camera, video otoscope, and digital stethoscope [11]. Initially designed for home use by caregivers, these devices allow pediatricians to receive real-time clinical information through a virtual connection. Similar telemedicine solutions are already implemented in several European countries and the United States, mainly in private health care settings [12,13].

When combined with these digital tools, video consultations can facilitate real-time collaboration between health care professionals. In this model, a nurse physically present with the patient performs the remote examination under the pediatrician's guidance, allowing both history taking and a basic remote physical examination to be conducted synchronously. As this interaction occurs between health care professionals, it is referred to as a video interconsultation.

This approach is particularly suitable for acute pediatric cases—commonly referred to as same-day or urgent visits—that require pediatric assessment within 48 hours. Implementing this model could enhance access to pediatric care in remote areas, promote territorial equity, and reduce unnecessary emergency department referrals.

However, the limited evidence on the use of digital tools such as video interconsultation in pediatric primary care highlights the need to develop and evaluate new technology-integrated models of care, especially in rural areas [14].

Objectives

This study aimed to evaluate the feasibility of a synchronous acute pediatric video interconsultation model that integrates a remote physical examination and is conducted between health care professionals, one of whom is physically present with the patient, in the rural primary care setting of Catalonia.

The study also sought to assess diagnostic adequacy compared with in-person visits and satisfaction among users and health care professionals, considering quality of care, patient safety, and key influencing factors such as reason for consultation, patient age, and visit duration.

This pediatric video interconsultation model is hypothesized to be a feasible, diagnostically adequate, and well-accepted approach in rural primary care settings.

RenderX

Methods

Study Protocol

The study protocol has been published in a separate publication [15].

Study Design

This was a prospective observational diagnostic accuracy study conducted in a real-world primary care setting, without modification of routine clinical practice. Each participant underwent both the index test (video interconsultation) and the reference standard (in-person visit) during the same clinical encounter, enabling a within-participant comparison of diagnostic performance.

Blinding of participants, clinicians, or outcome assessors was not feasible due to the design: the same pediatrician performed both evaluations sequentially in the same visit, and therefore, all parties were aware of the modality used. As the intervention was limited to a single synchronous video consultation per episode, the study design did not involve repeated use or longitudinal tracking of digital engagement.

Standard in-person pediatric assessment was selected as the reference comparator because it represents current clinical practice and the diagnostic gold standard in primary care.

The study follows the STROBE (Strengthening the Reporting of Observational Studies in Epidemiology) guidelines, incorporates relevant STARD (Standards for Reporting Diagnostic Accuracy Studies) principles, and adheres to CONSORT-EHEALTH recommendations, an extension of the CONSORT (Consolidated Standards of Reporting Trials) statement for reporting digital health interventions [16-18].

Setting and Period

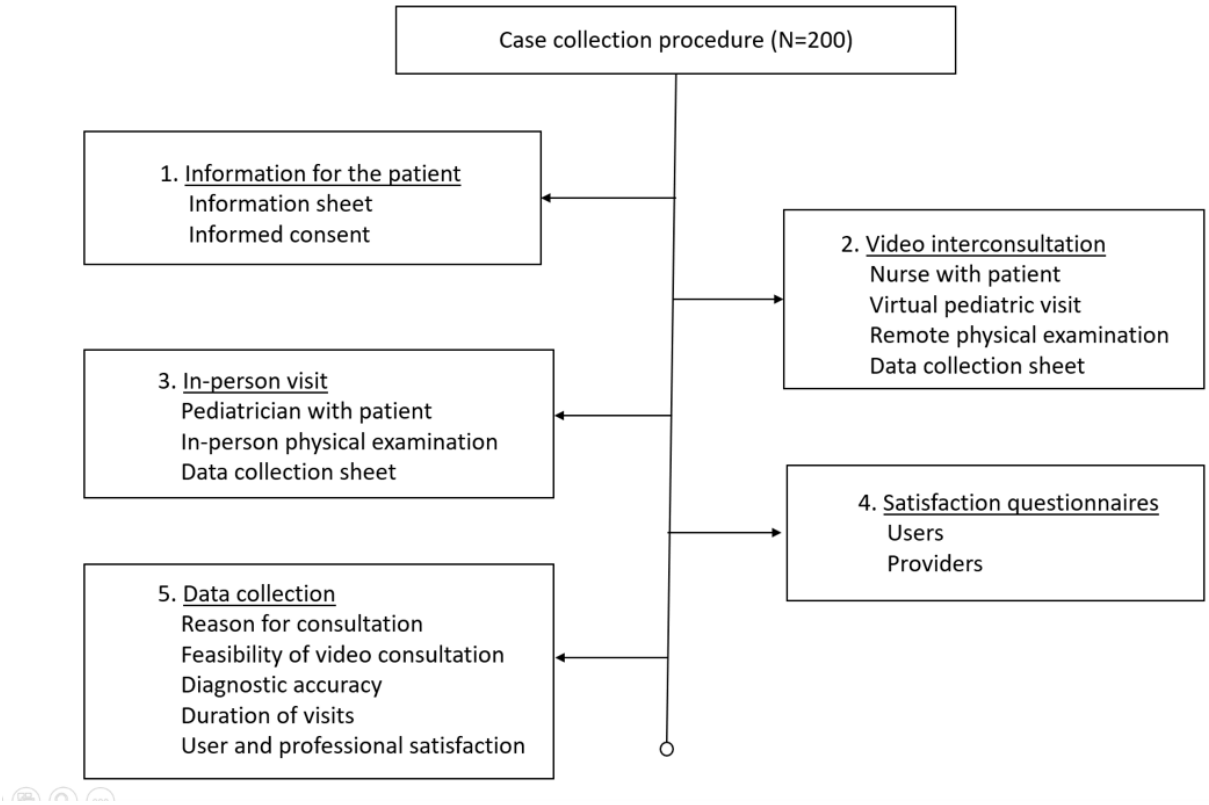
The study was conducted within the primary care network of the Central Catalonia Health Region (Institut Català de la Salut) at the Cardona Primary Care Center by the pediatric care team. This rural area provides services to approximately 5000 residents, including approximately 800 children aged 0 to 14 years, with a population density of 68 inhabitants per square kilometer.

Data collection took place from June 7, 2023, to January 22, 2025. Diagnostic confirmation occurred immediately after the video consultation through the in-person reassessment; therefore, no additional follow-up was required.

No technological or operational changes occurred during the study that could have affected the feasibility or diagnostic performance of video interconsultations.

Participants

Eligibility criteria included children aged 0 to 14 years presenting with acute conditions requiring care within 48 hours. Acute illness was defined as a condition requiring medical attention within 48 hours. Parental informed consent was mandatory.



The exclusion criteria were routine checkups, chronic condition follow-ups, emergencies requiring immediate in-person care, cases that could be managed autonomously by nursing staff, and an absence of informed consent.

Sample Size and Sampling

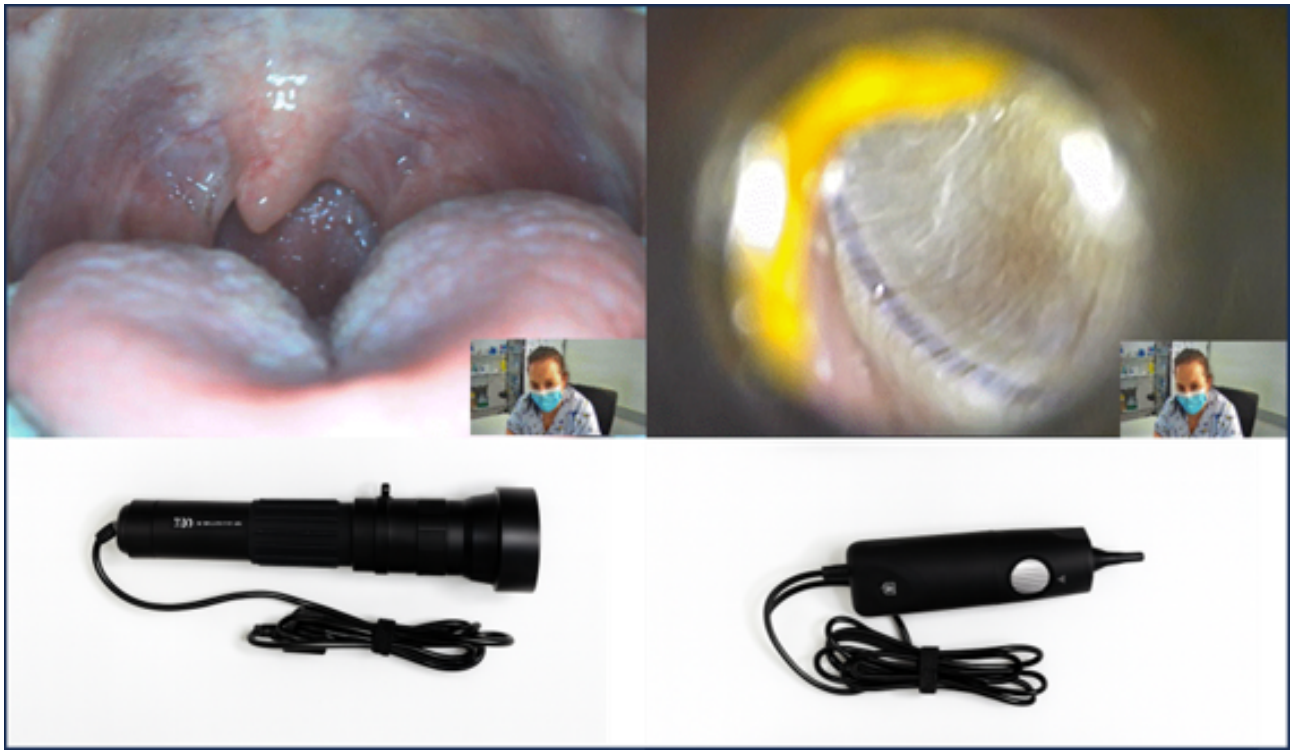
A convenience sample of all eligible cases was included. To ensure adequate power for the main objective, the minimum required sample size was estimated at 170 cases to assess the feasibility and diagnostic concordance of video interconsultations compared with in-person visits. The calculation was conducted using the GRANMO-DATARUS online tool, with a 95% CI, an 8% margin of error, and an anticipated 10% dropout rate [19]. A total of 200 cases were recruited. Participant flow is shown in Figure 1.

XSL•FO
RenderX

Figure 1. Sequential case collection process from recruitment and video interconsultation to in-person assessment, satisfaction evaluation, and data recording.

Digital Health Intervention and Procedures

Information and Consent



Families were informed in person by the pediatric nurse during the visit, before enrollment.

Video Interconsultation (Index Test)

A secure, encrypted Microsoft Teams video call connected the pediatrician remotely with the onsite nurse and patient. With the pediatrician's guidance, the nurse performed a physical examination using a digital camera, a video otoscope, and a digital stethoscope. A remote diagnostic impression was recorded. Example images are shown in Figure 2.

XSL•FO
RenderX

Figure 2. Images of the pharynx and tympanic membrane captured during the remote physical examination and the certified digital camera and digital video otoscope used in the study.

In-Person Reassessment (Reference Standard)

Immediately afterward, the same pediatrician performed a face-to-face evaluation and confirmed the final diagnosis.

Satisfaction Assessment

At the end of the visit, two brief questionnaires were administered: one for users (patients and families) and one for health care professionals (categorized as receiving pediatricians, assistant nurses, or observers).

Data Collection

Data were collected using Microsoft 365 Forms via encrypted institutional accounts and stored on secure health services servers. All participants were exposed; no comparison group was included. As this trial was conducted in a rural primary care environment, all video consultations were mediated by trained health care staff.

A total of three data collection tools were used: (1) a clinical form, (2) a professional satisfaction questionnaire (validated Catalan version of the Health Optimum Telemedicine Acceptance Questionnaire) [20], and (3) a user satisfaction questionnaire (adapted from the Northern Saskatchewan Telehealth Network) [21].

No privacy breaches or adverse events occurred. Technical issues were managed by redirecting participants to an in-person assessment when needed.

Variables

The following variables were collected to describe the characteristics of the sample and to assess the feasibility, diagnostic adequacy, and satisfaction associated with pediatric video consultations:

- Sociodemographic variables
  - Age: grouped into five 3-year intervals
  - Sex: female, male, or nonbinary
- Clinical variables
  - Reason for consultation: recorded individually and categorized by affected system or area (respiratory; otorhinolaryngology or ear, nose, and throat; gastrointestinal; infectious diseases; dermatology; musculoskeletal; ocular; and other)
  - Diagnosis: recorded individually and categorized using the same classification
- Feasibility variables
  - Feasibility: feasible or infeasible based on the ability to establish a safe and appropriate diagnosis. Patient safety indicators are included in feasibility, defined as the ability to reach a correct diagnosis without causing harm.
  - Duration of both consultations (in minutes)
  - Limiting factors of nonfeasibility: classified into 6 groups (need for in-person physical examination, telematic auscultation difficulty, camera visualization difficulty, video otoscope visualization difficulty, urgent demand, and lack of patient cooperation)
- Diagnostic adequacy variables
  - Diagnostic concordance: correct or incorrect, using the in-person visit as the gold standard
  - Sensitivity, specificity, and accuracy of the video interconsultation

XSL•FO
RenderX

- Satisfaction variables
- - Professional satisfaction score
  - User satisfaction score

Outcomes Measures

The primary outcomes were the feasibility and diagnostic accuracy of the pediatric video interconsultation model compared with in-person visits, as well as satisfaction levels among health care professionals and users.

The secondary outcomes included factors limiting feasibility (reason for consultation, patient age, and visit duration) and potential barriers identified during the implementation process.

Statistical Analysis

Categorical variables were summarized using absolute frequencies and percentages, whereas continuous variables were described using means and SDs. Associations between categorical variables were analyzed using the Pearson chi-square test or Fisher exact test when expected cell counts were less than 5. For continuous variables, comparisons were made using the *t* test or, when normality assumptions were not met, the Mann-Whitney *U* test.

Diagnostic performance of video consultations was evaluated using sensitivity, specificity, and overall diagnostic accuracy, considering the in-person assessment as the reference standard. CIs for accuracy estimates were calculated using the Wilson method. Diagnostic concordance was assessed using the Cohen κ coefficient, and Gwet's first-order agreement coefficient (AC1) was additionally computed to account for potential prevalence and bias effects. The binomial test was used to analyze the type and direction of diagnostic disagreements. When cell counts were small, estimates were interpreted with caution due to limited statistical power.

All estimates were reported with 95% CIs, and statistical significance was set at $P<.05$. Statistical analyses were performed using R software (version 4.0.3; R Foundation for Statistical Computing).

Ethical Considerations

This study was approved by the Ethical Committee for Research in Medicines of the Jordi Gol i Gurina Primary Care Research Institute (Barcelona, Spain; registration number 22/236-P; March 8, 2023).

As participants were minors, written informed consent from their parents or legal guardians was mandatory. Families received both oral and written information about the study at the time of the visit, before providing consent. The information included the study purpose, procedures (first, a video consultation performed with the pediatric nurse onsite while the pediatrician participated remotely, followed by a conventional in-person visit with the same pediatrician), eligibility criteria, potential risks, confidentiality, and lawful data protection. Participation was voluntary, and withdrawal was possible at any time without consequences for clinical care. Contact details of the principal investigator were provided to address any present or future questions. No images or videos were recorded during the video consultations, except in isolated cases where photographs of clinical findings were taken with explicit informed consent and used exclusively for research or training purposes, ensuring that patients could not be identified. Participants did not receive any financial or other form of compensation for participation in the study.

The telemedicine assessment was supplementary to standard in-person clinical care, ensuring that no diagnostic or therapeutic decisions relied solely on the digital evaluation. Video calls were conducted using secure and encrypted systems to ensure the confidentiality of clinical information.

All researchers signed a confidentiality agreement concerning the treatment and use of study data. No direct personal identifiers were collected, and all data were pseudonymized and processed confidentially. Access to the data was restricted exclusively to the research team. The project database is hosted on secure servers of the Primary Care Management and Community of the Catalan Health Institute (Institut Català de la Salut), which acts as the data processor. Data retention is planned for 10 years, and no international data transfers are anticipated.

The research team will only use the coded database for scientific purposes (eg, journal articles, scientific reports, and book chapters). The study was conducted in full compliance with the ethical principles of the Declaration of Helsinki (1964) and its latest amendment (Fortaleza, 2013), as well as with the European General Data Protection Regulation (GDPR EU 2016/679) and Spanish Organic Law 3/2018 on the Protection of Personal Data and Guarantee of Digital Rights.

Results

Participant Characteristics

A total of 200 pediatric video interconsultations for acute conditions were conducted in rural primary care. All diagnosis-related data were complete for all included cases; no missing diagnostic data were present. The sample distribution by age and sex, along with the main reasons for consultation, is summarized in Table 1. These reasons are provided both individually and grouped by system to facilitate analysis: respiratory, otorhinolaryngology or ENT, gastrointestinal, infectious diseases, dermatology, trauma, ocular, and other. The most prevalent reasons for consultation were respiratory, otorhinolaryngologic, and dermatologic conditions, with cough, earache, and skin lesions being the most frequent symptoms, followed in frequency by fever and odynophagia. Specific reasons for consultation for each organ system are provided in Multimedia Appendix 1.

XSL•FO

Table . Characteristics of the sample (N=200).

Characteristics	Values
Patient sex, n (%)	
Female	98 (49)
Male	102 (51)
Patient age (y), n (%)	
0 - 2	38 (19)
3 - 5	44 (22)
6 - 8	48 (24)
9 - 11	37 (18.5)
12 - 14	33 (16.5)
Grouped consultation reasons, n (%)	
ENT[a]	57 (28.5)
Respiratory	55 (27.5)
Dermatology	23 (11.5)
Infectious	21 (10.5)
Trauma	13 (6.5)
Gastrointestinal	11 (5.5)
Ocular	7 (3.5)
Other	13 (6.5)
Duration (min[b]), mean (SD)	
Video interconsultation	7.13 (3.85)
In-person visit	3.96 (1.57)
Feasibility video interconsultation, n (%)	
Feasible	129 (64.5)
Infeasible	71 (35.5)

[a]ENT: ear, nose, and throat.

[b]*P* value <.001 based on an independent samples Student *t* test.

Regarding consultation duration, video interconsultations had a significantly longer mean duration (*P*<.001) of 7.13 (SD 3.85) minutes compared with in-person visits, which had a mean duration of 3.96 (SD 1.57) minutes.

Feasibility

Video interconsultation was feasible in 129 (64.5%) of the 200 cases. In these visits, the video interconsultation could be completed appropriately, providing the necessary data to issue a reliable diagnosis while maintaining quality of care and patient safety.

In 71 (35.5%) cases, video interconsultation was not feasible. The causes were analyzed, and the most frequent cause of infeasibility was the inability to perform a complete physical examination electronically, requiring redirection to an in-person visit (27/71, 38%). Other limitations included difficulties in interpreting online auscultation (18/71, 25.4%), problems viewing images obtained with the digital camera (12/71, 16.9%), and problems with the video otoscope (10/71, 14.1%). In 5 (7%) cases, the consultation was urgent and could not be completed via video, and in 2 (2.8%) cases, the patient's lack of cooperation prevented completion. In 3 (4.2%) cases, there were combined technical difficulties, with simultaneous problems in interpreting images from both the digital camera and the video otoscope or in the quality of auscultation through the electronic stethoscope (Table 2).

XSL•FO
RenderX

Table . Reasons for infeasibility of video interconsultations and corresponding frequencies (N=71).

Reasons for video interconsultation infeasibility[a]	Frequency, n (%)
Need for an in-person physical examination	27 (38)
Difficulty with remote auscultation	18 (25)
Limited visibility through digital camera	12 (17)
Limited visibility through video otoscope	10 (14)
Urgent consultation required	5 (7)
Lack of patient cooperation	2 (3)

[a]Multiple reasons were reported in 3 cases.

A bivariate analysis was conducted to identify demographic and clinical variables potentially associated with the feasibility of video interconsultations.

Categorical variables, including patient sex, age group, diagnostic adequacy, and the clinical category of the consultation reason, were compared between feasible and nonfeasible cases using the chi-square test. A *P* value <.05 was considered statistically significant. No significant associations were found between feasibility and the patient's sex or age group.

However, a statistically significant relationship was observed between feasibility and the clinical category of the consultation reason. Consultations related to gastrointestinal, musculoskeletal, and other conditions showed a higher proportion of nonfeasible cases, whereas those for dermatologic, ocular, and otorhinolaryngologic conditions demonstrated a higher proportion of feasible cases.

Diagnostic adequacy was also significantly associated with feasibility, as all cases classified as feasible presented correct diagnostic agreement (*P*<.001; Table 3).

Table . Bivariate analysis of main variables by feasibility of telemedicine visits.

Variables	Infeasible (n=71)	Feasible (n=129)	*P* value[a]
Patient sex, n (%)			.21

Accuracy

Regarding diagnostic accuracy, diagnoses were grouped by system, using the same eight categories as the reasons for consultation: respiratory, otorhinolaryngology, gastrointestinal, infectious diseases, dermatology, trauma, ocular, and other. In all 129 cases in which video interconsultation was feasible, diagnostic concordance with the in-person visit was observed, as this was considered inherent to the concept of feasibility.

In contrast, among the 71 nonfeasible cases, diagnostic discrepancies between the video interconsultation and the subsequent in-person visit were identified in 36 instances. To calculate diagnostic agreement, 165 valid cases were included, as 35 cases were excluded because of insufficient data for diagnostic evaluation. Diagnostic concordance between the video interconsultation and the in-person assessment was observed in 129 (78.2%) of 165 feasible cases. In the remaining 36 (21.8%) cases, the diagnoses differed between the 2 assessment modalities. Figure 3 shows the flow of participants through the study and the diagnostic concordance analysis.

Cohen κ coefficient for telematic–in-person diagnostic concordance was 0.36, indicating fair agreement. However, given the unbalanced distribution of diagnostic categories, Gwet's AC1 coefficient was also computed, yielding a value of 0.67, which indicates substantial agreement, according to the Landis and Koch scale.

Figure 3. Flow of participants throughout the study according to diagnostic agreement analysis. The different percentages for all subgroups are indicated in relation to the corresponding group.

Among the 36 (21.8%; total 165) cases of showing a diagnostic discrepancy between the telematic and in-person assessments, 10 (27.8%) cases were attributed to the need for a complete physical examination to establish an accurate diagnosis. The distribution of these cases was as follows: 5 involved the musculoskeletal system, 3 were related to the gastrointestinal system, 1 was related to infectious diseases, and 1 was related to other conditions.

Of the remaining 26 (72.2%) discordant cases, the type of diagnostic discrepancy and its distribution by organ system and specific diagnosis were analyzed (Table 4). Most discrepancies were underdiagnoses (23/26, 88.5%), while 5 (19.2%) cases represented overdiagnoses. The exact binomial test showed that the proportion of underdiagnoses was significantly greater than 50% (95% CI 69.8% - 97.6; P<.001).

XSL•FO
RenderX

Table . Types and frequencies of diagnostic discrepancies between video interconsultations and in-person visits (n=26).

Discrepancy type (video interconsultation vs in person)	Cases[a] n (%)
Underdiagnosis of respiratory conditions	
Bronchospasm	6 (23.1)
Respiratory superinfection	4 (15.4)
Bronchiolitis	1 (3.8)
Overdiagnosis of respiratory conditions	
Bronchospasm	2 (7.7)
Underdiagnosis of ENT[b] conditions	
Acute otitis media	3 (11.5)
Herpangina	3 (11.5)
Otitis externa	2 (7.7)
Streptococcal pharyngitis	1 (3.8)
Dental abscess	1 (3.8)
Overdiagnosis of ENT conditions	
Acute otitis media	3 (11.5)
Underdiagnosis of dermatology conditions	
Atopic dermatitis	1 (3.8)
Scarlet fever	1 (3.8)

[a]One case involved both underdiagnosis in the respiratory system and overdiagnosis in ENT. Another case showed both underdiagnosis and overdiagnosis within ENT.

[b]ENT: ear, nose, and throat.

Of the 23 (88.5%; total 26) underdiagnosed cases in the video interconsultation assessment, 11 (%) corresponded to the respiratory system, 10 (%) corresponded to otorhinolaryngology, and 2 (%) corresponded to dermatology. The distribution of underdiagnoses by organ system did not differ significantly from a uniform distribution (Fisher exact test, P=.08).

Regarding overdiagnosis, of the 5 (19.2%) detected cases, 2 (%) involved the respiratory system, and 3 (%) involved the otorhinolaryngology system. Given the small sample size, no specific pattern could be confirmed or ruled out, and the Fisher exact test also showed no significant deviation from a uniform distribution (P≈.6).

In 2 cases, both underdiagnosis and overdiagnosis occurred simultaneously and were therefore classified in both categories. In 1 case, overdiagnosis involved an otorhinolaryngologic condition and underdiagnosis a respiratory one; in the other, both diagnoses were within otorhinolaryngology, where acute otitis media was incorrectly diagnosed instead of otitis externa during the video interconsultation.

The accuracy, sensitivity, and specificity of each diagnosis obtained via video interconsultation were estimated using the in-person diagnosis as the gold standard. Importantly, the mean diagnostic accuracy of video interconsultations across all conditions was 0.99 (95% CI 0.98 - 1.00). The mean overall specificity was 0.99 (95% CI 0.98 - 1.00), and the mean overall sensitivity was 0.90 (95% CI 0.84 - 0.95).

The diagnostic performance metrics for each clinical category, organized by organ system, are summarized in Table 5. A high level of diagnostic agreement was observed between video and in-person consultations across all categories, with accuracy values exceeding 0.92 and ranging from 0.93 to 1.00. Video interconsultations demonstrated the best performance for otorhinolaryngologic, dermatologic, and trauma-related conditions, which also showed high sensitivity and specificity. In contrast, respiratory diagnoses had lower sensitivity (0.68, 95% CI 0.51 - 0.82), suggesting a potential risk of diagnostic underestimation during video interconsultations. Detailed diagnostic performance metrics by specific condition, along with the corresponding frequency distribution, are provided in Multimedia Appendix 2. CIs should be interpreted with caution in categories with small sample sizes.

Professional Satisfaction

Professional satisfaction, assessed through the validated Catalan version of the Health Optimum Telemedicine Acceptance Questionnaire, was analyzed by comparing responses across three professional groups—receivers (pediatricians), assistants (nurses), and observers (residents and students)—using the chi-square tests (Table 6).

In terms of perceived quality, 74% (148/200) of professionals rated the video interconsultation as equal to or higher than in-person care, whereas 26% (52/200) perceived it as lower. This assessment differed significantly among professional groups (P<.001). Nursing assistants expressed the most favorable opinions (42/47, 89.4%, positive ratings), similar to observers (41/46, 89.1%), whereas receivers (pediatricians) were less favorable, with 50.5% (54/107) positive and 43% (46/107) negative ratings.

Overall, 94.5% (189/200) of participants believed that telemedicine could have a positive impact on patient health, 4.5% (9/200) thought it had no influence, and 1% (2/200) considered that it might worsen patient outcomes. When analyzed by professional group, receivers reported in 99.1% (106/107) of visits that telemedicine could improve patient health, compared with 78.7% (37/47) among assistants and 100% (200/200) among observers. Among assistants, 4.3% (2/47) indicated that telemedicine could negatively affect patients' health.

With respect to the continuity of telemedicine use, 83.4% (166/199) of professionals indicated that improvements were needed in infrastructure or organization. Receivers were particularly likely to request such improvements (96/107, 89.7%), compared with assistants (15/47, 31.9%) and observers (7/45, 15.6%; one observer did not provide a response to this item).

Differences among professional groups were statistically significant for both perceived quality (P<.001) and willingness to continue using telemedicine (P=.004).

[c]One observer did not provide a response to this item.

User Satisfaction

User experience, measured using a survey adapted from the Telehealth Network Questionnaire (Northern Saskatchewan Telehealth Network) and completed by the accompanying adults responsible for the child, was rated as very good in 74.5% (149/200) of the 200 cases and good in 20.5% (41/200). A total of 4.5% (9/200) of participants described the experience as poor, and 0.5% (1/200) of participants described the experience as very poor (Table 7).

In addition, 92% (184/200) of families reported that they would be willing to repeat the video interconsultation in the future (142/200, 71%, very likely, and 42/200, 21%, likely), whereas only 8% (16/200) expressed reluctance (12/200, 6%, unlikely and 4/200, 2%, very unlikely).

To explore whether these perceptions were shared by health care professionals, a correlation analysis between user and professional satisfaction for each visit revealed a weak but statistically significant positive correlation (r=0.182, 95% CI 0.044 - 0.312; P=.009).

Table . Users' satisfaction with telemedicine and video interconsultation (N=200).

Opinion users	Total, n (%)
Overall quality	
Very good	149 (74.5)
Good	41 (20.5)
Poor	9 (4.5)
Very poor	1 (0.5)
Willingness to repeat	
Very likely	142 (71)
Likely	42 (21)
Unlikely	12 (6)
Very unlikely	4 (2)

Discussion

Principal Findings

This study evaluated whether a synchronous video consultation model—including remote physical examination guided by a pediatrician and supported by an onsite pediatric nurse—is a feasible, clinically appropriate, and well-accepted approach to managing acute pediatric conditions in rural primary care in Catalonia.

Feasibility was achieved in nearly two-thirds of cases, allowing completion of a safe and adequate remote assessment. Among feasible cases, diagnostic performance was high, with substantial agreement between telemedicine and in-person evaluations. Video consultations also demonstrated high diagnostic accuracy and sensitivity, along with near-optimal specificity. However, performance varied by clinical condition, suggesting that limitations inherent to remote assessment (eg, reduced ability to detect subtle clinical signs) may reduce sensitivity in certain scenarios.

Process outcomes further supported implementation: satisfaction was very high among families and positive among health care professionals, and consultation duration remained acceptable despite the inclusion of a remote physical examination.

Together, these findings indicate that—when appropriate feasibility and safety criteria are met—this telemedicine model can effectively complement, rather than replace, in-person pediatric care in underserved regions, thereby contributing to improved health equity and accessibility.

Furthermore, these findings could be applicable to other pediatric primary care settings with similar digital infrastructure and staffing resources. However, as this was an observational, single-center study without randomization, these findings should be interpreted with caution regarding their external validity.

Comparison With Prior Work

These results are consistent with the current literature suggesting that telemedicine in pediatrics can achieve high diagnostic validity when applied under well-defined conditions. That said, most previous studies were not conducted in primary care settings, did not address acute conditions, and primarily examined video consultations between professionals and patients, rather than between professionals themselves [22-24]. There is limited evidence on video consultations that incorporate physical examinations. In pediatrics, Wagner et al [25] found that remote physical examination using medical devices similar to those used in this study was comparable to in-person assessment. Their findings align with ours, showing high diagnostic accuracy for otoscopy, oropharyngeal evaluation, and dermatological examination, but lower accuracy for assessing abdominal pathology.

Several studies have found that the effectiveness of video consultations is particularly high for diagnoses that rely primarily on medical history and visual assessment, such as upper respiratory tract infections (eg, pharyngitis and otitis) or dermatologic lesions [26,27]. In contrast, conditions that require a full physical examination, such as abdominal pain, which necessitates palpation, or headache, which may call for a neurological evaluation, may show reduced sensitivity, as also observed in this study [25,28].

This limitation may increase the risk of incomplete or inaccurate diagnoses, as reflected in the 21.8% (36/165) of cases that showed diagnostic discordance between virtual and in-person visits. While most discrepancies were classified as underdiagnoses or overdiagnoses, some involved mixed errors. Several cases required referral to in-person care to complete the physical examination and establish a reliable diagnosis, underscoring the complexity of remote clinical assessment. Furthermore, in some cases classified as infeasible, the online and in-person diagnoses were consistent, and the infeasibility was attributed to other limitations. In pediatric care, particularly for younger children, a comprehensive physical examination is often performed regardless of the presenting complaint. These findings underscore the need for triage and feasibility criteria tailored to the specific characteristics of each patient and condition to optimize the safety and effectiveness of video interconsultations. They also highlight the importance of establishing clear clinical guidelines to ensure the safe, high-quality use of video interconsultations in primary care pediatrics.

Pediatric patients with specialty conditions, such as rheumatologic, cardiologic, or endocrinologic disorders, were not included, as no such cases were seen during the study period. However, a few neurology and gynecology cases were included in the “other” category due to their small number. It is worth noting that telemedicine has also proven useful for the follow-up of pediatric rheumatic diseases, particularly in rural areas and during the COVID-19 pandemic [29].

Regarding consultation duration, a 2022 review by the Catalan Agency for Health Quality and Evaluation reported that video or telephone consultations are typically 1.5 to 4 minutes shorter than in-person visits [30]. In contrast, in this study, video interconsultations lasted nearly twice as long as in-person visits, likely due to the inclusion of a physical examination, which extended the consultation time. Additionally, this model involved 2 health care professionals. While it may enhance accessibility, it also requires greater resource allocation in terms of time and staffing.

Regarding users’ perceptions of telemedicine, the findings of this study indicate a high level of satisfaction, consistent with previous research [31]. The main reasons families expressed concerns about remote interconsultations were technical issues related to sound, connectivity, and image quality, as well as fears that in-person care might be replaced by virtual services. Other reasons, such as a perceived lack of safety, were infrequent. In any case, it is essential to provide families with clear and transparent information so they can make informed decisions about using this technology. Ultimately, they remain at the center of care [32].

With regard to health care professionals’ perspectives on telemedicine, the results indicate that professionals acknowledge the value of pediatric video interconsultations, and most consider them beneficial for patient health. However, differences among

XSL•FO
RenderX

professional groups suggest that perceptions vary depending on each participant's clinical role and expectations.

These findings are consistent with those of Martín-Masot et al [33], who analyzed the views of Spanish pediatricians following the rapid digitalization of health care delivery during the COVID-19 pandemic. In their study, most pediatricians regarded digital consultations as time-efficient and a valuable resource, aligning with the present results. Among nurses, the majority reported that the quality of video consultations was equal to or better than that of in-person visits. These results align with the findings of Navarro-Martínez et al [34], who reported that telenursing is positively perceived in routine clinical practice. However, most health care professionals in this study identified the need to improve the application of telemedicine in clinical settings, particularly in terms of technology, organizational processes, and bioethical considerations. This observation is echoed in a study conducted in Catalonia by Vidal-Alaball et al [35]. Similarly, other studies, such as that by Inoue et al [36] in Japan, have reached the same conclusions. In this context, it is essential to train professionals not only in the use of digital tools, but also in what Finkelstein et al [37] refer to as "webside manner," a more effective approach to online clinical communication.

Furthermore, although telemedicine can improve communication between doctors and patients and help reduce health care costs, it may compromise the quality of care, therapeutic effectiveness, and patient safety if not implemented properly [38]. Therefore, legislation and bioethical frameworks must evolve to accommodate these emerging models of care [39].

Limitations

This study has several limitations. First, there is a potential risk of diagnostic inaccuracy in video consultations compared with in-person visits, especially for conditions that require a direct physical examination, such as abdominal pain, trauma, or headache. Technical issues affecting image or audio quality may also hinder adequate remote assessment. Additionally, some diagnostic subgroups were small, which reduced the precision of accuracy estimates and widened the CIs.

Confirmation bias may have occurred because the same pediatrician conducted both the telemedicine and in-person evaluations. A role bias may also have occurred, as those receiving telemedicine may have different experiences from those delivering or observing it. If recipients represent the majority, as in this case, overall satisfaction may primarily reflect their perspective. Likewise, observers may have overemphasized methodological aspects while underestimating the actual user experience.

Another limitation is a possible social desirability bias, as the project was conducted by the patients' regular and trusted pediatrician and nurse. This relationship of trust may have influenced participants' responses, although no intentional intervention or influence was exerted during data collection.

Operational limitations should also be considered. Video consultations took longer than in-person visits and required the presence of both a pediatrician and a nurse, which may not be feasible in all settings and could increase the workload. Economic, organizational, and technological implications were not evaluated in this study, and the environmental impact of digital health equipment warrants further attention.

Finally, data were collected in a single rural primary care center, which may limit the generalizability to other health care settings. Despite strict data protection measures, concerns about confidentiality and the potential for digital care to reduce the human component of clinical interaction remain relevant considerations.

Future Directions

Future research should focus on defining evidence-based triage and feasibility criteria to select patients who can be safely and effectively managed through video interconsultation. Larger multicenter studies are needed to confirm diagnostic performance and satisfaction outcomes across broader pediatric populations and health care contexts. Evaluating economic, organizational, and environmental sustainability will be essential to inform real-world implementation. In addition, exploring strategies to streamline the workflow, optimize technical reliability, and maintain the human aspects of care will help ensure successful and responsible integration into routine pediatric practice.

Conclusions

The proposed model of synchronous video consultation between health care professionals, including physical examination, has proven to be a feasible option. It shows good diagnostic agreement with in-person visits and has been positively evaluated by both users and health care professionals.

This approach may serve as a valuable tool for managing acute pediatric conditions in rural primary care settings in Catalonia, provided it is implemented appropriately and maintains patient safety and quality of care. Although it cannot replace in-person visits, it can complement them within the ongoing reorganization of pediatric primary care, contributing to improved accessibility, territorial equity, and system efficiency.

The implementation of this model involves several challenges, including longer consultation times, training requirements, the development of standardized protocols, economic and environmental costs, and the management of data confidentiality.

Acknowledgments

This study was conducted within the PhD Program in Medicine and Biomedical Sciences at the University of Vic – Central University of Catalonia. The study also received support through a research release fellowship granted by Institut Català de la

Abstract

Background: Using social media to deliver e-cigarette cessation interventions to young people is a promising approach, but low participant engagement and retention may undermine intervention efficacy. Peer mentoring holds great potential to address these issues.

Objective: This study aimed to understand the feasibility and acceptability of integrating peer mentoring into a social media–based intervention to help young people quit e-cigarette use.

Methods: We conducted a single-arm pilot trial with 24 e-cigarette users (aged 16 - 21 years). Participants were assigned to 1 of 2 Instagram groups, where they received an existing vaping cessation intervention, Quit the Hit (QTH), in which a trained counselor posted 1 to 3 evidence-based vaping cessation messages on weekdays over 5 weeks. As an adjunct to QTH, each group included 2 peer mentors of similar age as participants who had successfully quit vaping. The mentors provided social support and shared their quitting experiences. Participants completed a baseline survey and a follow-up survey at the end of the intervention (week 5) and were invited to participate in postintervention focus groups.

Results: Participants' mean age was 18.6 (SD 1.2) years, and 58.3% (14/24) were male. Most (20/24, 83.3%) identified as straight/heterosexual, 29.2% (7/24) identified as non-Hispanic White, and 45.8% (11/24) were high school students. On average, participants vaped e-cigarettes 5.1 (SD 1.7) days per week, and 33.3% (8/24) reported daily vaping. All participants (24/24, 100%) had made at least one quit attempt in the past year. Nearly all participants (23/24, 95.8%) engaged in the group by either posting or liking others' comments at least once. Mean program engagement was 28.8 (SD 27.3) posts or likes over the 5 weeks. The study retention rate was 91.7% (22/24) at week 5. Using an intent-to-treat approach, 66.7% (16/24) of participants were abstinent (7-day point prevalence abstinence) at week 5. On a 5-point Likert scale, participants rated peer mentoring as highly useful (mean 4.6, SD 0.3) and reported high levels of satisfaction (mean 4.7, SD 0.3). All participants who completed the follow-up survey said they would recommend the program to others. Focus group findings supported these results, highlighting positive feedback on both the quality and usefulness of peer mentoring and the peer-mentored version of the QTH program. Suggestions for future improvements were also discussed.

Conclusions: Integrating peer mentoring into social media–based e-cigarette cessation interventions for young people is feasible and acceptable. Participants engaged in the intervention and demonstrated strong retention. They rated both the peer mentoring and the overall program highly. Self-reported abstinence at 5 weeks was high. Larger trials are warranted to evaluate the efficacy of the peer-mentored intervention.

Introduction

As cigarette smoking has declined after decades of tobacco control efforts, e-cigarettes have become the most commonly used tobacco product among adolescents and young adults [1,2]. Among US adults, young adults reported the highest rate of e-cigarette use, with 11% to 18% reporting vaping in the past 30 days [3-5]. According to the 2024 National Youth Tobacco Survey, 5.9% of middle and high school students (1.6 million) reported current e-cigarette use [6]. While the long-term effects of e-cigarette use are not yet fully understood, evolving evidence indicates an increased risk for respiratory and cardiovascular diseases [7-9]. In addition, early exposure to nicotine may increase the risk of addiction [10,11] and the likelihood of initiating cigarette smoking later in life [12-14]. A meta-analysis published in 2018 found that, after adjusting for established risk factors for cigarette smoking, youth e-cigarette users had nearly 4 times higher odds of subsequent cigarette smoking [15]. More recent meta-analyses of longitudinal studies have further confirmed the association between e-cigarette use and subsequent smoking among nonsmoking adolescents and young adults [14]. Quitting tobacco before age 30 reduces most tobacco-related health risks [16]; therefore, it is crucial to provide effective vaping cessation support for adolescents and young adults [17].

The growth of social media use among young people [18] makes it a potentially ideal channel for delivering vaping cessation interventions to adolescents and young adults [19,20]. Previous studies on social media–based smoking cessation interventions have shown feasibility, acceptability, and early efficacy [19]. However, despite these promising findings, social media interventions have reported large reductions in engagement over time and high dropout rates [19,20]. For instance, the Tobacco Status Project (TSP), a smoking cessation intervention for young adults delivered via Facebook groups, found that the number of participant comments decreased over time in each group despite variation between groups [21]. User engagement with cessation interventions has been found to be associated with retention and abstinence outcomes [22,23], highlighting the need to improve participant engagement to enhance the effectiveness of social media interventions.

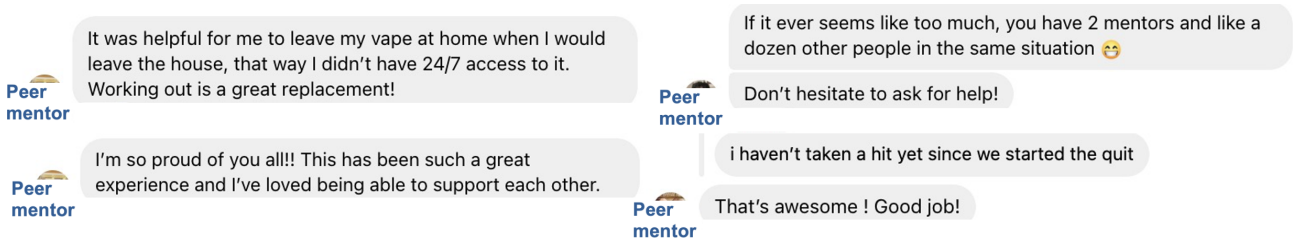
The scientific literature suggests that peer mentoring may be a promising strategy to engage participants and address the issue of decreasing engagement and low retention in social media–based interventions. The model of supportive accountability [24], grounded in organizational psychology, motivation theory, and computer-mediated communication research, posits that human support from a trustworthy, benevolent, and competent source helps digital intervention participants stay engaged and adherent to interventions by offering social support and accountability. It also suggests that peer mentors can be especially effective because individuals often feel more at ease with those who are similar to themselves [24]. As a peer support strategy, peer mentoring is a process in which individuals with similar life experiences provide encouragement and assistance to foster health behavior change [25]. Previous studies with young people have shown that tobacco use is susceptible to peer influence [26-28]. Incorporating peer mentoring into vaping cessation programs may be effective because peers who have successfully quit are more relatable than health care professionals or adult facilitators [25,29]. Peers' personal experiences may show that cessation is achievable, and their social support may be more engaging for participants [30]. Peer mentoring has been adopted by various health promotion programs [31-33], including smoking cessation programs [34,35], yet it has not been used to address e-cigarette use in the context of social media. In this study, we aimed to evaluate whether integrating peer mentoring into social media–based interventions to support e-cigarette cessation among young people was feasible and acceptable.

Methods

We conducted a single-arm pilot trial that integrated peer mentoring into an existing Instagram-based vaping cessation program, Quit the Hit (QTH), to assess feasibility and acceptability quantitatively. Postintervention focus group discussions were conducted with participants to contextualize the quantitative findings.

Intervention Design

QTH is a 5-week program that delivers evidence-based vaping cessation content in groups via direct messages on Instagram. QTH was developed by a University of California, San Francisco research team in partnership with outside agencies (HopeLab and Rescue) and based on the TSP discussed above, which showed efficacy in delivering a smoking cessation intervention to young adults in private Facebook groups [36]. QTH convenes Instagram direct-message groups of 10 to 15 participants facilitated by a professional tobacco cessation counselor; the counselor delivers up to 3 posts per weekday. Content includes evidence-based vaping cessation strategies, incorporating skills from cognitive behavioral therapy and the transtheoretical model that have demonstrated efficacy for long-term smoking cessation [37]. Additional details about QTH have been published previously [38].



Peer mentoring was provided by young adults aged 18 to 29 years who had used e-cigarettes, had previously participated in QTH support groups, and had successfully quit vaping for more than 3 months. This 3-month threshold was used because abstinence at 3 months is a commonly reported benchmark in tobacco cessation research for "successful" short-term sustained cessation [39], although it does not eliminate the possibility of relapse. Peer mentors received a 4-module mentor training (basic information about e-cigarettes and health risks, mentoring relationships and skills, emotional intelligence, and boundary setting and confidentiality) and passed a posttraining qualification assessment that included a knowledge test and scenario-based questions. The mentoring relationships and skills module was a live Zoom training with a trained counselor, while the other modules were provided as recorded trainings that mentors completed on their own time. The training modules were adapted from a previous peer-mentored smoking cessation intervention and informed by our formative research on mentors' training needs and participants' expectations [35,40] and consultations with experts in vaping cessation, peer mentoring,

XSL•FO
RenderX

and youth-serving programs, with the goal of preparing mentors to effectively fulfill their mentoring roles.

Peer mentors posted in the QTH groups to provide emotional support, often sharing their personal experience with quit attempts and offering encouragement. Figure 1 shows examples of peer mentor posts in the QTH groups. In each peer-mentored QTH group, there were 8 to 12 participants, 2 peer mentors, and a professional tobacco cessation counselor. Participants could direct-message their mentors to receive one-on-one peer mentoring if they were uncomfortable reaching out in the group setting. Peer mentors sent each participant a check-in message around the third week. Program features, such as the age range of peer mentors, group size, and mentor-mentee ratio, were informed by our formative study [40].

Figure 1. Screenshots of peer mentor posts in Instagram groups illustrating emotional support.

Participants and Recruitment

Participants were recruited through social media advertising (Meta Ads, including Facebook and Instagram, and TikTok advertising), recruitment messages distributed by youth-serving community organizations, and outreach to participants of a previous randomized controlled trial (RCT) testing QTH [38] who did not quit vaping by the end of the trial. The recruitment message included a link and QR code to the study's website, where eligibility was screened. Eligible participants were able to read English, aged 13 to 21 years, used social media at least 4 days per week, vaped at least once per week in the past 30 days, indicated that they were considering or interested in quitting within the next 6 months, and resided in California. Participants were asked to show photos of their ID and vape devices to verify their age and vaping status during study enrollment.

Study Procedures

After giving consent and completing a baseline survey, participants were assigned to one of the 2 support groups based on timing of enrollment. The first 12 participants were assigned to group 1, and the next 12 were assigned to group 2. After participants joined the group, we reviewed the ground rules with participants, including expectations for respectful behavior and confidentiality (ie, what is said in the group stays in the group). The intervention lasted 5 weeks. At the end of the intervention, participants were asked to complete a follow-up survey and were invited to participate in a 90-minute focus group via Zoom. The focus group discussion asked participants to reflect on their experiences with peer mentoring and the overall intervention and to provide suggestions for future improvements. Focus group discussions were video recorded and professionally transcribed.

Measures

Overview

Both baseline and follow-up surveys were administered online via Qualtrics (Qualtrics, Inc). Participants reported their sociodemographic characteristics, e-cigarette use, and quitting-related factors, such as quit attempts, desire to quit, and confidence in quitting. Measures of feasibility (including engagement and retention) and acceptability (including perceived usefulness of peer mentoring, satisfaction with peer mentoring, and evaluation of the program) were adapted for use in a vaping cessation context based on prior pilot trials for smoking cessation with and without peer mentors [35,38,41].

Feasibility

Feasibility was assessed by participant engagement in the Instagram group, as indicated by the number of likes and comments documented by study staff, which is consistent with previous social media interventions [41] and the retention rate. Retention was measured as the proportion of enrolled participants who completed the follow-up survey.

Perceived Usefulness of Peer Mentoring

Perceived usefulness was assessed in the follow-up survey with 9 items, measuring agreement on a 5-point Likert scale (1=disagree a lot to 5=agree a lot). Example items included the following: "The peer mentors helped me quit vaping," "The peer mentors shared useful information on quitting," and "The peer mentors increased my confidence that I can quit."

We calculated an index of the overall perceived usefulness as the mean of responses across all 9 items.

Satisfaction With Peer Mentoring

Satisfaction with peer mentoring was assessed in the follow-up survey with 6 items, measuring agreement on a 5-point Likert scale (1=disagree a lot to 5=agree a lot). Example items included the following: "I liked the peer mentoring in the program," "I felt comfortable with the messages I got from peer mentors," and "The peer mentors sent messages at convenient times of day."

Additionally, participants rated their satisfaction with the quantity of peer mentor posts on a 5-point scale by responding to the item, "Overall, the number of messages from peer mentors was …" (1=too few, 2=few, 3=about right, 4=many, and 5=too many).

Evaluation of the Program

The overall evaluation of the peer-mentored vaping cessation program was measured with 4 items, measuring agreement on a 5-point Likert scale (1=disagree a lot to 5=agree a lot). The 4

XSL•FO
RenderX

items were the following: “I would recommend this program to others,” “The program gave me something new to think about,” “I thought about what I read in the program” and “The program was easy to understand.”

Data Analysis

We summarized descriptive statistics for participant characteristics, feasibility, and acceptability as indicated by perceived usefulness, satisfaction, and evaluation of the program, and other variables of interest. A series of comparisons about e-cigarette use were made between preintervention and postintervention data, but given the small sample size, no inferential statistics were used. All analyses were conducted using SPSS (version 26; IBM Corp).

We adopted a thematic analysis approach to analyze qualitative data from 2 focus groups (5 participants total), with the assistance of Dedoose software (SocioCultural Research Consultants). Using a data-driven inductive approach, one author (JCL) reviewed all transcripts from both groups and developed the initial coding guide. With this guide, 2 authors (JCL and KS) independently coded the transcripts and resolved any discrepancies through discussion. Analytic memos were written during the independent coding phase and later discussed to refine the coding guide. Given the focus of this study and limited number of focus group participants, thematic saturation was not the goal of the qualitative analysis; instead, we aimed to identify key points expressed by participants regarding their experiences in the program to contextualize the quantitative findings.

Ethical Considerations

This study received approval from WIRB-Copernicus Group Institutional Review Board (protocol T31IR1910). The trial was registered at ClinicalTrials.gov (NCT07437196). Participants completed online informed consent, consistent with standard care for adolescents in smoking cessation treatment [42]. Participants received electronic gift cards for completing the baseline survey and follow-up survey. They received US $10 for completing the baseline survey and US $20 for completing the follow-up survey, with a US $5 bonus per survey for completion within 24 hours of receiving the survey link. Participants who completed the 90-minute postintervention focus group received US $50. Peer mentors received US $30 for completing the saliva test for biochemical verification of abstinence and US $50 for completing peer mentor training and passing the subsequent assessment. They also received US $250 at the end of the 5-week program for their effort.

Results

Participant Characteristics

Among the 24 participants, 15 were recruited via TikTok ads and 9 were recruited from a list of prior QTH RCT participants who met eligibility criteria, including 7 from the control group and 2 from the intervention group. Table 1 shows the details of the participant characteristics. Participants were predominantly male (n=14, 58.3%). While participants aged 13 to 21 years were eligible, the enrolled participants ranged in age from 16 to 21 years, with a mean age of 18.6 (SD 1.2) years. Most participants (n=20, 83.3%) identified as straight or heterosexual, 7 (29.2%) identified as White, and almost half (n=11, 45.8%) were high school students. All participants reported vaping in the past 7 days, with an average of 5.1 (SD 1.7) days per week, and 8 (33.3%) participants reported vaping daily. On vaping days, the average number of puffs was 31.6 (SD 62.5). A total of 8 (33.3%) participants reported using e-cigarettes within 30 minutes of waking. Overall, participants reported strong motivation to quit. All participants (n=24, 100%) had made at least one quit attempt (ie, stopped vaping nicotine for 1 day or longer) within the past 12 months, and on a 1- to 5-point scale (5=very much), the average desire to quit was 4.5 (SD 0.6), and the average confidence in quitting was 4.0 (SD 1.0).

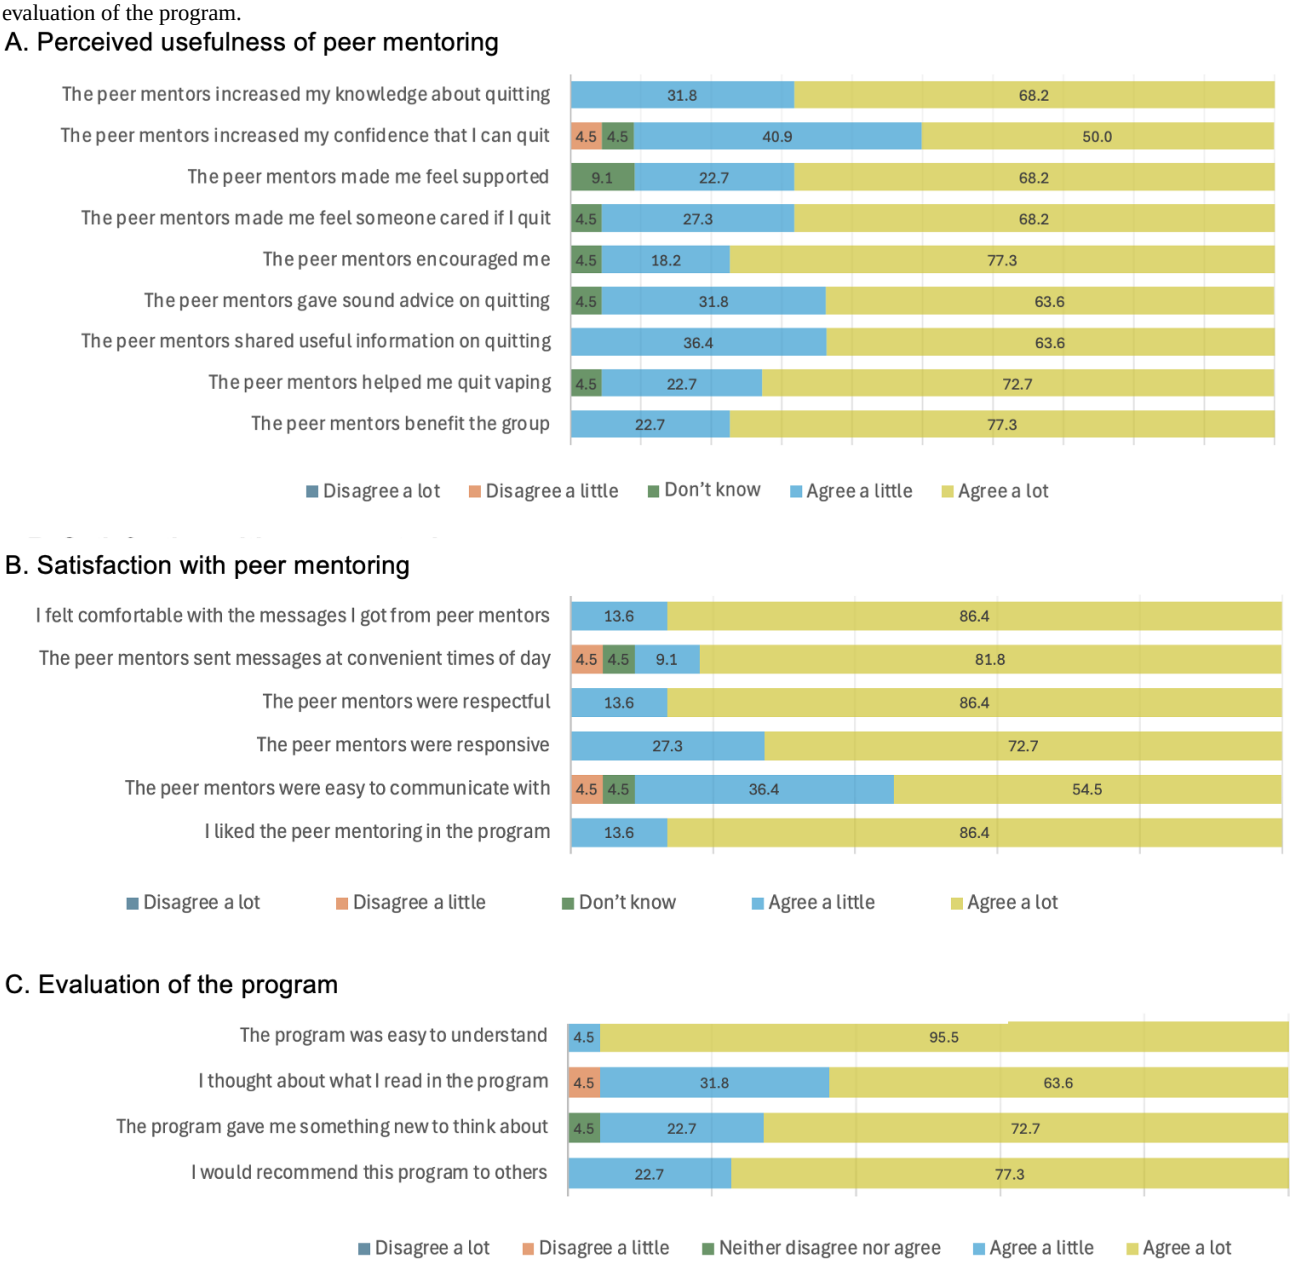
[a]LGBTQ+: lesbian, gay, bisexual, transgender, queer or questioning, or others.

[b]GED: General Educational Development.

Feasibility: Engagement and Retention



Almost all participants (23/24, 95.8%) engaged by posting or liking comments in the group at least once during the program. Combining posting and liking, participants engaged with the program a mean of 28.8 (SD 27.3) times and median 15.5 (IQR 9.0-44.8) times over the 5 weeks. There was no substantial difference between group 1 (median 18.0, IQR 9.3-61.3) and group 2 (median 13.0, IQR 9.0-44.3). Specifically, of the 24 participants, 23 (95.8%) posted at least once during the program. The mean number of posts per person was 18.6 (SD 18.5), and the median number of posts was 10.0 (IQR 8.0-26.3). Excluding the 1 participant who never posted, individual post counts ranged from 1 - 67. A total of 21 (87.5%) participants ''liked'' at least one post in the group. The mean of "likes" per person was 10.3 (SD 11.1). The median number of "likes" was 5.5 (IQR 1.0-18.8). Among those who "liked" at least once, individual "like" counts ranged from 1 - 38. At week 5, 22 (91.7%) participants remained in the group and completed the follow-up survey.

XSL•FO
RenderX

Perceived Usefulness of Peer Mentoring

Peer mentoring provided in the group was perceived to be highly useful (Figure 2A). All participants agreed that their peer mentors increased their knowledge about quitting, provided useful information, and benefited their group. Nearly all participants (21/22, 95.5%) agreed that the mentors showed care, offered encouragement, gave good advice, and helped them quit vaping. A total of 90.9% (20/22) of participants reported that the mentors boosted their confidence in quitting and made them feel supported. Across the 9 items measuring perceived usefulness, the mean score was 4.6 (SD 0.3) out of 5.

Figure 2. Proportion (%) of responses for acceptability measures. (A) Perceived usefulness of peer mentoring; and (B) satisfaction with peer mentoring; (C) evaluation of the program.

Satisfaction With Peer Mentoring

The participants expressed very high levels of satisfaction with the peer mentoring they received in the group (Figure 2B). All participants agreed that they liked the peer-mentoring component, felt comfortable with the messages they received, and found the mentors respectful and responsive. Most (20/22, 90.9%) participants also agreed that the mentors sent messages at convenient times and were easy to communicate with. Across the 6 items measuring satisfaction with peer mentoring, the mean score was 4.7 (SD 0.3) out of 5. In addition, 86.4% (19/22) of participants felt the number of messages from peer mentors was "about right," 9.1% (2/22) thought there were "few," and 4.5% (1/22) thought there were "many." No participant selected the options of "too few" or "too many."

Evaluation of the Program

The participants evaluated the peer-mentored vaping cessation program highly (Figure 2C). All participants agreed with the statements "I would recommend this program to others," and "The program was easy to understand." Nearly all participants (21/22, 95.5%) agreed that "The program gave me something

XSL•FO
RenderX

new to think about," and "I thought about what I read in the program."

Vaping Abstinence Outcomes

Using an intent-to-treat approach, 66.7% (16/24) of participants reported being abstinent at the end of the program based on 7-day point prevalence abstinence. Of the participants who completed the follow-up survey, 72.7% (16/22) reported being abstinent at 5 weeks. Among participants who had not quit, the average number of vaping days per week was 1.8 (SD 1.2) days, lower than the average of 5.1 (SD 1.7) days per week at baseline, and no participant reported daily vaping at follow-up. Similarly, the average number of puffs per vaping day decreased to 5.7 (SD 4.7) puffs, compared with 31.6 (SD 62.5) puffs at baseline.

Focus Group Findings

We conducted 2 postintervention focus groups with 5 participants from the 2 groups (1 female and 4 male). Three participants reported abstinence and 2 did not, and 3 had participated in a prior QTH group without peer mentors. The following themes were identified: appreciation of having peer mentors, communication with mentors, feedback on program setup, privacy and boundaries, advice for improvement, and willingness to be a future mentor.

All 5 participants expressed high satisfaction with the peer mentoring they received, valuing both mentors' approachable communication style, characterized by respect and responsiveness, and their steady support. One participant noted the following (theme: appreciation of having peer mentors):

> *I feel like they're the most helpful with just general support. I have the group as community support overall, but the peer mentors serve as kind of an anchor... I feel like the peer mentors were really stable source of support in the group and I feel like that was a benefit.*

Some participants who had previously participated in a QTH group without mentors recalled that a large number of participant posts off the topic of vaping cessation discouraged participation, and this was improved with peer mentors:

> *I had muted it around week two... every hour that I would get a notification of 99 plus messages... the actual topics of conversation were not beneficial to quitting and we're completely off of what should be discussed.*

By comparison, these participants felt that peer mentors' presence in the group discussions kept the group focused and on track (theme: appreciation of having peer mentors). They were also satisfied with the number of times their mentor messaged them and the wait time before receiving a response (theme: communication with mentors). The group size and ratio of mentors to mentees were considered acceptable, as noted by one participant (theme: feedback on program setup):

> *Both of my mentors were pretty active, so I always felt like they were around. So, I thought two was the perfect number.*

Participants appreciated being offered the options of peer mentoring both one-on-one and in the group setting (theme: feedback on program setup). They mentioned that the peer mentors fostered a welcoming environment in the group, which also facilitated comfort with one-on-one mentoring. Among the 5 focus group participants, 3 direct-messaged their mentors (themes: feedback on program setup and communication with mentors):

> *I feel like the way he interacted in the group chat first also made me feel comfortable to reach out. He seemed very open.*
>
> *It's like you get to know them and the DMs, it's a lot more personal, ... I like that we have both options instead of one.*

Although all participants agreed that one-on-one support was a valuable supplement to group discussions, they had mixed views on peer mentors proactively direct-messaging them. Most participants appreciated it and felt it increased their sense of connection to the group, with one participant noting the following:

> *I thought that this program and the group chat was very helpful, especially the mentors, especially when they DM me personally, so I never felt that way of leaving the program, and they really helped us quit.*

However, one participant felt pressured by the DM and said they might have considered leaving the group if they received more (theme: privacy and boundaries).

Participants in the focus group also affirmed core components of the QTH program and believed some helped with the mentor-mentee relationship (theme: feedback on program setup). For instance, the counselor posted Monday roll calls as brief check-ins in the group chat that invited members to respond to a fun question or prompt. Participants felt that these posts helped maintain engagement, and they described the group-based design as both supportive and motivating. As one participant explained:

> *I guess the motivation was just other people—seeing other people also trying to achieve the same goal as me. It just pushes you forward instead of relying on your own goals, so you get inspiration from other people.*

While participants wanted the program to focus on vaping cessation, they also appreciated that not all questions were strictly about vaping. For example, a question from QTH asked, "If you were a food what food would you be?" and a participant answered, "I'd be a grape because I want to be with my friends all the time." They felt that having nonvaping-related interaction questions once a week was just the right amount and helped keep them engaged and connected with both their peers and the mentors.

When asked for suggestions to improve the program, participants recommended incorporating more personal interactions, such as video messages, video meetings, and designated office hours for real-time support (theme: advice for improvement). Several noted that a mentor had used a video self-introduction, which was very well received. As one participant shared:

> *It seems like they sent you a personal message even though it's sent to everyone. I feel like that [sending*

XSL•FO
RenderX

a video message] would help you get to know them just a little bit better.

They also suggested that the QTH counselor share more resources during the program, particularly on Fridays, so they could review the materials over the weekend when there were no messages from the counselor in the group. Additionally, a couple of participants expressed a desire for a longer intervention than 5 weeks to further support abstinence. Participants did not indicate any further concerns with the peer-mentored QTH program, participant safety, or privacy. Two participants also expressed interest in serving as peer mentors in future cohorts (theme: willingness to be a future mentor).

Discussion

Principal Findings

Our study found that integrating peer mentors who had successfully quit vaping into QTH, an Instagram-based vaping cessation program, was both feasible and acceptable. While the study was not designed to formally assess efficacy, using an intent-to-treat analysis, 66.7% (16/24) of participants reported 7-day point prevalence abstinence. Postintervention focus groups provided qualitative data confirming that participants highly valued the peer mentoring in the program, found the peer mentors helpful in their quit efforts, and endorsed a peer-mentored approach. Together, these findings underscore the promise of peer-mentored, social media–based vaping cessation interventions and the need for future trials to assess their efficacy.

Overall, engagement in the peer-mentored QTH intervention was encouraging. QTH was adapted from the Facebook-based TSP smoking cessation intervention for young adults that showed efficacy. We used the same engagement metrics (ie, number of comments and likes) as in the TSP pilot lasting 90 days. In the TSP pilot, 61% (48/79) of participants commented on at least one post and 51% (40/79) liked at least one post, compared with 95.8% (23/24) and 87.5% (21/24), respectively, in our peer-mentored intervention. The median number of comments was higher in our intervention than in TSP (15.5 vs 12), and the median number of likes was also higher (5.5 in our intervention vs 4 in TSP) [41]. TSP did not report mean overall program engagement, limiting direct comparison on this metric. However, mean program engagement in the peer-mentored intervention was 28.8 (SD 27.3) posts or likes, which was lower than the mean of 47.5 posts or likes in the QTH RCT [43]. This may partly be explained by the large number of nonvaping-related engagement, as noted by our postintervention focus group participants who had been recruited from the QTH RCT and did not successfully quit. It should also be noted that participants reported sending DMs to their mentors during the peer-mentored program; however, one-on-one peer mentoring via DMs was not captured as an engagement metric because the research team could not access these messages outside the group. Therefore, we may have understated participant engagement in the peer-mentored QTH program.

Regarding retention at the end of intervention, TSP reported 76% (60/79) retention [41], the QTH group in an RCT without peer mentoring reported 48.4% (124/256) retention [44], and our QTH group with peer mentoring achieved 91.7% (22/24) retention. However, the program durations differed (90 days in TSP vs 5 weeks in QTH), and recruitment strategies also varied across studies; therefore, the presence of peer mentoring may not fully explain the differences in study retention. The purpose of incorporating peer mentoring as a source of social support was to enhance participant engagement, which is a key driver of retention. Although we could not statistically establish the relationships among these factors, both the observed engagement metrics and qualitative feedback from postintervention focus groups suggest that peer mentoring is a promising and well-received strategy for increasing topic-focused engagement in social media–based interventions. Further research is recommended to clarify these relationships.

We also found high levels of satisfaction with and perceived usefulness of peer mentoring among the participants. Participants expressed high levels of satisfaction, as indicated by high mean values. All participants who completed the follow-up survey agreed that their peer mentors "increased [their] knowledge about quitting," "shared useful information on quitting," and "benefited the group." Focus group discussions echoed these findings, revealing that peer mentors benefited the group by keeping the conversation focused on quitting, compared with programs without peer mentoring. Participants also expressed strong satisfaction with the peer mentoring they received in the group, highlighting easy and comfortable communication, a respectful and responsive style, messages sent at convenient times and in appropriate amounts, and the effective combination of one-on-one and group mentoring. All participants agreed with the statement, "I like the peer mentoring in the program." Participants' positive responses to the current peer-mentoring approach reflect the success of incorporating our formative findings into program development and underscore the potential of this approach for future interventions [40]. Beyond the very positive perception of peer mentoring itself, participants also highly rated the peer-mentored version of the QTH program, with all indicating that they "would recommend this program to others."

One consideration for implementing peer mentoring is the additional resources required to train, support, and compensate peer mentors, which increase program cost and complexity. However, this model remains more efficient than in-person peer-mentoring programs, which require more substantial resources [34]. Our participants' strong evaluations of both the peer mentoring and the peer-mentored intervention as a whole highlight the potential of a geographically unrestricted, low-cost peer support model. Moreover, participants expressed interest in serving as peer mentors themselves, suggesting the potential to develop a large, sustainable mentor pool to support subsequent cohorts of individuals seeking to quit.

Though this pilot study focused on feasibility and acceptability, 72.7% (16/22) of participants who completed the follow-up survey reported abstaining at the end of the intervention. Using an intention-to-treat approach, the reported 7-day point prevalence abstinence rate was 66.7% (16/24), which is higher than the self-reported abstinence rate at the end of intervention in the QTH group without peer mentoring (67/256, 26.2%) [44]

XSL•FO
RenderX

and TSP (9/79, 12% in its pilot test [41] and 23/251, 9.2% in its RCT [36]). Compared with the QTH RCT, participants in this study included fewer daily users, reported lower frequency of nicotine use, had lower levels of nicotine addiction as measured by time to first use upon waking, and showed higher motivation to quit. As a result, peer mentoring alone may not fully explain the observed differences in abstinence. While self-reported data from unblinded participants may not accurately reflect participants' actual quit status, these findings suggest that peer mentoring has the potential to improve abstinence from e-cigarette use and warrant further research to assess efficacy. Additionally, focus groups provided valuable insights for future peer-mentored intervention design, such as increased use of videos to enhance interaction, opportunities for real-time support, and ways to extend the intervention duration to help sustain abstinence.

Limitations

This study has several limitations. First, intervention participants were recruited from California only, and most had a strong desire to quit vaping. As a result, the findings of this pilot trial may not be fully generalizable to e-cigarette users in other regions or to those less motivated to quit. Second, abstinence data were self-reported and not biochemically validated. Third, the small number of pilot groups and focus group participants may not reflect the full range of participant experiences. The limited number of focus group participants also precluded the achievement of thematic saturation. Fourth, as a pilot study, the limited sample size does not allow the establishment of relationships between peer mentoring, engagement, and outcome variables. Future studies, such as RCTs or those using a multiphase optimization strategy design, are recommended to rigorously evaluate the efficacy of peer mentoring in supporting young people's e-cigarette cessation.

Conclusions

This study found that integrating peer mentoring into vaping cessation interventions delivered in groups on a social media platform is both feasible and acceptable. Participants rated both peer mentoring and the overall peer-mentored program highly. Self-reported 7-day point prevalence abstinence at the end of the intervention was very promising. These findings support a future full-scale trial to evaluate the efficacy of peer-mentored social media–based vaping cessation interventions.

Abstract

Background: Teachers have the potential to be influential figures in school-based health promotion as informal caregivers; yet little is known about what motivates them to initiate preventive conversations with students. Attribution theory offers a useful framework to explore how perceptions of responsibility shape communicative behavior, but it has rarely been applied in the context of teacher-student interactions around health risks such as smoking.

Objective: This study applies the attribution theory to explore the motivational drivers that lead teachers to initiate discussions with adolescents about smoking.

Methods: Data were collected from 101 middle schools in the Canton of Ticino, Switzerland, as part of a larger longitudinal study. The analysis focuses on 67 teachers who participated in the first wave. Responsibility attribution, concern, and previous classroom sanctions were examined in association with teachers' communication.

Results: Results from a moderated mediation model showed that teachers who attributed greater responsibility to the school (internal attribution) reported higher levels of concern (β=–0.41; *P*=.002) and engaged in more frequent in-class discussions on smoking (β=–0.26; *P*=.02). Although concern alone was not directly related to communication (β=–0.14; *P*=.22), its effect was significantly moderated by contextual sanctions (β=1.01; *P*<.001).

Conclusions: These findings highlight the motivational and contextual factors that shape teachers' communication with students on smoking behavior. By applying attribution theory in the novel context of health communication, this research contributes to understanding how perceived responsibility influences preventive communication in schools.

Introduction

Overview

Imagine being a teacher (if you are not already one) faced with the challenge of addressing the topic of health prevention with your students. Now imagine feeling directly responsible for these young individuals, knowing that their future may, in part, depend on what you teach them, and becoming aware of the weight your words might carry in shaping their behavior. It is reasonable to assume that such awareness, this sense of responsibility, would significantly influence what you say in the classroom to prevent adverse behaviors, especially if your class is known for behavioral issues or has previously faced disciplinary actions. Conversely, suppose that while looking at these 20 or so faces, you are convinced that students' health is

XSL•FO
RenderX

entirely the responsibility of their parents. You are convinced that your role does not extend to teaching healthy behaviors, and you therefore feel no personal involvement in their long-term health. In such a case, you would likely be less inclined to engage with them in conversations aimed at preventing risky behaviors.

This is precisely the central focus of the research presented in this study: it concerns the motivational foundations of in-class teachers' communication on smoking and applies attribution theory, originally developed by Heider [1] within psychology, to the novel and previously unexplored domain of teachers' health communication with students in educational settings.

Research on the impact of communication on adolescent smoking has traditionally emphasized the influence of parents and peers [2]. Teachers, on the other hand, spend a similarly significant amount of time with adolescents but have received comparatively limited attention [3-5]. The school environment has been broadly considered in previous research [6,7]. What has been overlooked is the specific role of teachers in deterring adverse behaviors, with some early exceptions [8].

To address this gap, this research draws on the longstanding psychological framework of attribution theory to explore the mechanisms that may prompt teachers to initiate conversations about smoking. Although attribution theory has been successfully applied to explain pupil motivational drive or achievement evaluation in educational contexts [9-11], its use in communication research, particularly health communication, remains limited. Notably, in their contribution to the book *Communication and Learning*, Waldeck and Labelle [11] propose future research directions that include "extending its use to examine the relationship of instructor attribution of student behavior of corresponding communication behaviors both in and outside the classroom environment" (page 70). Although more than a decade has passed, this research cue has not yet been pursued. This study directly responds to this call by demonstrating the value of applying attribution theory to teachers' interactions with students in the context of smoking prevention, contributing to a sparsely developed body of literature on teachers as active agents in health-related communication.

The following sections provide a detailed exploration of the literature supporting this inquiry, including teachers' role in adolescents' health, the context of adolescent smoking, and, finally, past work that has applied attribution theory.

Teachers' Role

Schools have long been the focus of numerous intervention programs aimed at reducing adolescent smoking [12,13]; yet the specific role of the adults who share this environment with students—namely, teachers—remains understudied [2,8]. Anecdotal evidence highlights the potential influence teachers can exert on students; many can recall a particular teacher whose words or actions left a lasting impression. This influence is unsurprising given that adolescents spend approximately 5 to 7 hours per day in close interaction with teachers during critical developmental years. Moreover, teachers can impact learning across cognitive, affective, and behavioral domains [14,15].

Teachers play a central role in adolescents' lives, acting as a bridge between the adult world, represented by institutions and society, and the private, familial world of childhood [8]. Importantly, teachers are both accessible and cost-effective to involve in health-related initiatives, given that their professional role already encompasses a form of authority that is qualitatively distinct from that of parents [6]. Furthermore, their position grants them a dual role: as socializers guiding adolescents into adulthood and as communicators capable of voicing students' needs to other adults. This dual function highlights their unique capacity to mediate between adulthood and childhood [8].

The teacher-student relationship has been shown to significantly affect a variety of health behaviors [16]. For example, Voisin et al [17] found that students reporting high levels of teacher connectedness were less likely to engage in adverse behaviors such as gang membership, risky sexual encounters, and substance use. Communication, specifically, has been identified as a key factor in enhancing the efficacy of intervention programs. Effective teacher communication has been defined as a set of communicative behaviors that improve learning [18]; this concept can be extended beyond academic topics to include health-related behaviors. In the study by Mesman et al [19], clear communication from teachers improved outcomes in interventions targeting alcohol use and physical activity. These findings suggest that a similar influence may extend to other health behaviors, such as smoking, although further studies will need to confirm this relationship.

Understanding the motivational processes that drive teachers to engage with students in conversation about health behavior is crucial, as it opens the door to developing strategies that support and enhance teacher-led communication as a form of school intervention. This is precisely why the theoretical framework adopted in this study is particularly well suited: to effectively increase teacher engagement in preventive communication, efforts must target the motivational grounds for such communication. Among these, perceived responsibility for adolescent health can be a promising factor. By increasing the perception of responsibility, it could be possible to foster more frequent and meaningful communication, ultimately leading to a higher impact of prevention on adolescent smoking.

Adolescents' Smoking

The urgency of addressing adolescent smoking stems not only from its well-documented health consequences, such as respiratory disorders, cardiovascular diseases, and cancer, as highlighted by the review by Arafa et al [20], but also from its negative effects on cognitive development. Tobacco use during adolescence has been shown to hinder the development of brain networks and cognitive functions. Nicotine products are, without a doubt, toxic to the neurodevelopment of young people [21-23].

Beyond its impact on individual health, the global tobacco industry contributes significantly to environmental degradation, including deforestation, air and water pollution, biodiversity loss, and greenhouse gas emissions [24-26]. As such, smoking represents a critical behavior to target, not only for personal health but also for environmental protection. Preventing smoking initiation during adolescence is especially critical, as early

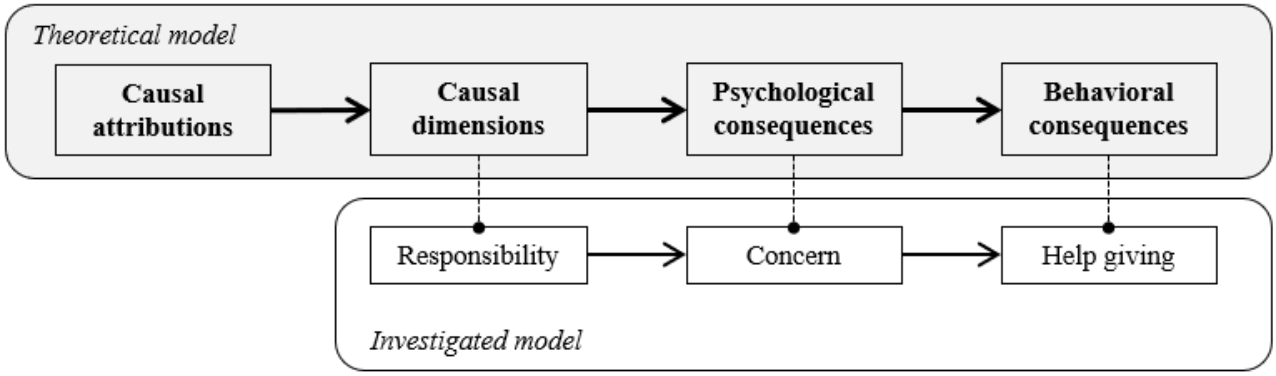
XSL•FO
RenderX

smoking onset significantly increases the likelihood of long-term tobacco consumption [27].

Recent data confirm that adolescent smoking remains a pressing global public health issue, with notable prevalence rates reported even in high-income countries with strict regulations. For example, the Health Behavior in School-Aged Children study indicates that a substantial percentage of youth experiment with or regularly use tobacco products, with nearly a quarter of adolescents aged 15 years reporting having ever smoked [28]. Adolescent smoking is strongly influenced by psychosocial factors such as peer norms, social identity, and stress—factors that make this period especially critical [29-32].

This underscores why the timing of intervention is crucial: adolescence is a developmental window during which risk-taking increases [33]. In this context, teachers are unique figures who can influence adolescent health trajectories. Their presence and authority place them in a powerful position to support early prevention efforts. Moreover, addressing adolescent smoking cannot be left solely to families or health care systems. Schools represent a critical institutional setting for early prevention, not only because they welcome a great variety of young people but also because they provide opportunities for sustained interaction between students and educators, which can foster trust and influence over time.

Attribution Theory



This study applies attribution theory, first developed by Heider [1] and further elaborated by Weiner [34]. It has been successfully used for decades in motivational research, social psychology, and educational psychology [35], but has rarely been applied in the context of health communication. According to this theory, individuals ascribe causality, and subsequently responsibility, to events and behaviors in their everyday lives [36]. These attributions, often made unconsciously, help understand why people do what they do and what motivates them to engage or disengage in specific behaviors [37].

Attributions are shaped in accordance with preexisting beliefs and are characterized by three distinct dimensions: (1) locus of causality, (2) stability, and (3) controllability [9,35,37-40]. The locus of causality refers to whether the cause of an event is attributed to personal characteristics within one's control (ie, internal attributions) or external factors beyond one's control (ie, external attributions) [38-41]. The stability dimension, as the name suggests, refers to the perceived consistency of the cause over time, whether it is a fixed trait or a fluctuating condition [38,39]. Lastly, the controllability dimension concerns whether the cause is perceived as subject to personal control and is closely tied to perception of personal responsibility [38]. Although this dimension was not part of the original formulation—as it was added by Fiske [42]—it has since been included as a "proximal critical cognitive consequence" of causal attribution [38,43]. This last dimension is the focal point of the research presented here.

In practice, individuals evaluating a situation unconsciously assess the cause of an event or behavior, including how responsible they feel in that situation [44]. This attribution directly shapes their behavioral response, as each evaluation elicits distinct psychological and behavioral consequences, such as help giving or help seeking [9,44].

The model tested in this paper is depicted in Figure 1 and shows the linear framework outlining the pathway from causal attribution to causal dimensions, then to psychological consequences, and lastly to behavioral consequences. The linear framework outlines the pathway from causal attribution to causal dimensions, then to psychological consequences, and lastly to behavioral consequences. This study focuses on the final 3 components of the model to examine their relevance within the teacher-student communication context. Specifically, the causal dimension triggered by the attribution is the feeling of personal responsibility; the psychological consequence is the rise of the social emotion of concern; and the behavioral consequence is help giving, through the form of communication [9].

Figure 1. Representation of the attributional model tested.

Exploring each component in more detail, the attribution of responsibility in educational contexts has been the subject of several studies, with both students and teachers as attributers [45-47]. In one section of the systematic review conducted by Wang and Hall [38] focused on teachers' attributions, the authors present 9 papers that specifically examine teachers' perceptions of responsibility. However, the studies presented are exclusively on responsibility in relation to academic performance, without addressing either health-related themes or the communicative behaviors between teachers and students.

Regarding the psychological consequences of the causal attribution, concern has been selected as a social emotion, consistent with the definition given by Burnett et al [48] as an emotion that involves mentalizing about other people. Concern arises in social contexts in which individuals affect one another's

XSL•FO
RenderX

emotional state [49]. In the context of this study, the emergence of teacher concern for students is expected to be influenced by whether teachers feel responsible for their students' health behavior.

Lastly, help giving has been operationalized as communication: the first step in supporting students within the context of smoking prevention is the act of speaking to them about the issue and drawing their attention to its risks. Whether through advice, emotional support, or information sharing, communication can fulfill the function of helping others, particularly in contexts in which direct intervention is limited. This has been demonstrated in studies on doctor-patient communication and online support groups [50-52]. In the case of smoking prevention, the most accessible and powerful tool teachers possess—aside from disciplinary measures—is their ability to educate adolescents about the harmful effects of tobacco use. Teachers' communication skills have been consistently associated with more effective learning outcomes [53] and the success of intervention programs [19,54]. Moreover, training in communication is frequently identified as a strategy for improving teacher efficacy [55]. Together, these findings underscore the central role of communication as a vehicle for preventive action in school settings.

Building on the theoretical framework presented thus far, we can summarize the core logic: hypothetically, teachers who feel personally responsible for preventing smoking among their students should experience greater concern than those who place responsibility externally. This heightened concern should in turn increase their motivation to protect students through communicative engagement in the classroom. In this way, communication could become the behavioral outcome of an attribution-based emotional and cognitive process—bridging the sense of responsibility and the intention to help students. This framework highlights the relevance of attribution theory in explaining the motivational base for health-related communication.

Contributions of This Study

Based on the literature review, several gaps emerge that this study seeks to address. The first concerns the attribution of responsibility by teachers: no past research, to the best of the authors' knowledge, has uncovered who is deemed responsible in the eyes of teachers for smoking prevention. Furthermore, in the context of tobacco consumption, it is not known how the attribution of responsibility affects communicative behavior: the motivational drivers behind teachers' decisions to engage in conversations with students about smoking remain underexplored. While existing research provides some evidence of teachers' influence on adolescent health behaviors, little is known about their personal motivators or decision-making processes in initiating such communication. To address this, the study tests the linear model proposed by Graham [9], grounded in Weiner's [39] attribution theory, focusing on concern as a social emotion that mediates the relationship between attribution of responsibility and communication.

In addition to this theoretical contribution, the study introduces a novel contextual variable not previously discussed in the literature review: the smoking behavior of students. This variable has been operationalized in this study as the presence or absence of prior sanctions for smoking, considering that this information implicitly includes the teachers' perception of classroom smoking behavior. This element is hypothesized to moderate the relationship between teachers' concern and their likelihood of communicating about smoking. Specifically, the expectation is that highly concerned teachers will be less likely to initiate discussions in classrooms in which no sanctions have previously been applied compared with those teaching in classes with a history of disciplinary action related to smoking. This reflects the idea that contextual cues, such as prior disciplinary actions, may shape whether emotional concern is translated into communicative behavior.

These considerations lead to the development of the study's central research question and hypotheses, summarized in Table S1 in Multimedia Appendix 1. They aim to empirically test both the motivational and contextual factors driving teacher-student communication on smoking prevention.

Research Question and Hypotheses

The study was guided by the following research question (RQ) and hypotheses (HP):

- RQ1: To whom do teachers attribute responsibility for preventing students from smoking?
- HP1: Attributing responsibility to the school context (ie, internal locus of responsibility) is associated with engaging in more discussion on smoking with students compared with attributing responsibility to parents (ie, external attribution of responsibility).
- HP2: Concern about future problems resulting from smoking (M), as a psychological consequence, will mediate the link between responsibility attribution (X) and in-class communication (Y).
- HP3: The presence or absence of sanctions applied to the class will moderate the relationship between concern and communication. Specifically, higher concern is expected to be associated with more frequent communication when students have previously received sanctions for smoking.

Methods

Ethical Considerations

The study was conducted according to the guidelines of the Declaration of Helsinki. The questionnaire and methodology for this study were approved by the Cantonal Bureau for Education in the Canton of Ticino, Switzerland (September 2017). No exemptions from ethics review were applicable. Written informed consent was obtained from participating teachers at the beginning of data collection; participants were informed that their participation was voluntary and that they could withdraw at any time without explanation. To protect their privacy, all data were anonymized using alphanumeric codes. No financial or other compensation was provided.

Procedure

This research is part of a larger longitudinal study involving teachers, parents, and adolescents from a representative sample of 101 middle schools in the Canton of Ticino, Switzerland.

XSL•FO
RenderX

The Canton of Ticino is located in the southern part of Switzerland, and the official language is Italian. As of 2024, the canton accounts for 4% of the total Swiss population (354,023 permanent residents), and the proportion of young people aged 15 years or younger has been steadily decreasing, reaching 12.6% of the total population in 2023 [56].

The study aimed to investigate the evolution of various health behaviors from the perspective of adolescents, their parents, and their teachers.

In September 2017, marking the beginning of data collection, a random sample comprising 66% of all first-year public school classes from the 5 areas of the canton was selected. The school sample was randomly selected to ensure representation of the broader school population. Private schools were also invited to participate; 1 of 3 agreed to participate, and 1 class was randomly selected. The final sample consisted of 101 classes from 36 schools (35 public and 1 private). Each class designated a reference teacher who could voluntarily participate in the study. The data analyzed in this study refer to the 67 teachers who voluntarily participated in the first wave of data collection, conducted at the end of the 2018 school year. The response rate was 66.3%, which is relatively high given that the questionnaire was administered at the end of the academic year, when teachers are usually engaged in closing activities and planning for the summer recess.

Paper questionnaires were distributed to all participating schools for completion by adolescents, parents, and teachers. Reference teachers were asked to complete the survey at the end of school board meetings, ensuring they had an up-to-date understanding of the classroom context. Once completed, they were asked to return the questionnaires to the university using a preaddressed, stamped envelope.

Participants

Of the 67 teachers who participated, 60% (40/67) identified as female, 30% (20/67) as male, and 10% (7/67) did not disclose their gender. In 88% (56/67) of the cases the role of reference teacher was assumed by the class teacher, a key figure in educational system of Ticino, responsible for mediating between the school and the families, as well as evaluating students' performance and workload [57]. The remaining respondents (11/67, 12%) identified themselves as members of management or as subject-specific lecturers. Participating teachers taught their class for a minimum of 2 hours and a maximum of 10 hours per week (mean 4.98, SD 2.10 hours), and more than three-quarters (41/67, 77%) had at least 5 years of teaching experience in middle school. Overall, teachers reported an average of 11.8 (SD 8.41) years of teaching experience and a mean employment rate of 81.3% (SD 22.90%).

Materials

Overview

The questionnaire used in the longitudinal study included both validated scales and ad hoc items developed specifically for this data collection. The following section describes the variables included in the model presented in this study.

Responsibility Attribution

Attribution of responsibility was measured using a set of 8 items covering both health-related and educational behaviors. For this study, only the item related to smoking was analyzed. Participants responded to the general prompt, "In your opinion, which of the following educational goals are the responsibility of the school, and which are the responsibility of the parents?" with 1 of the specific goals being: "Ensuring that children do not smoke." Responses were rated on a 7-point Likert scale, where 1 indicated full responsibility attributed to the school, 4 indicated shared responsibility, and 7 indicated full responsibility attributed to parents. Responses attributing responsibility to the school were considered an internal attribution, as teachers are part of the school context and their answers reflect both their own behavior and their awareness of institutional norms and practices. Conversely, attributing full responsibility to parents was regarded as an external attribution.

Concern

Teachers' concern was assessed with the following item: "How concerned are you that the following behaviors may lead middle school students to have problems in their future lives?" A list of 8 adverse behaviors was provided, including "cigarette consumption." Responses were recorded on a 5-point Likert scale (1=not at all and 5=very).

Sanctions

Teachers were asked to consider the past academic year and indicate "on how many occasions students in the class [insert class evaluated] were appropriately sanctioned if they performed any of the following behaviors." Sanctions could have been issued by the teacher himself or by a colleague. For this study, only the responses for smoking cigarettes were used. The response option was a 6-point Likert scale (0=this type of incident never occurred and 6=always). As the item, in its original formulation, contained two types of information—(1) the presence or absence of sanction and (2) the appropriateness of the sanctions—the researchers dichotomized the variable to isolate the first type of information. In this recoding, a response of 0 was retained as reference category to indicate that no sanctions were applied, while all other response options (1 through 6) were recoded to 1, signifying that a sanction was given to the class.

Communication on Smoking

The amount of communication in the classroom regarding health issues was measured with the following item: "During this school year, how often have you or other teachers discussed the following issues with the class [insert class evaluated]?" A list of 4 topics was presented, including tobacco use. Teachers could respond on a 4-point scale (1=never and 4=often).

Hours of Teaching (Covariate)

To control for time spent with the students, teachers were asked to indicate the number of hours they taught each week in the classroom being evaluated. This variable was treated as continuous.

XSL•FO
RenderX

Data Analysis Plan

The required sample size was determined using G*Power (version 3.1.9.7) [58]. A minimum of 51 participants would be needed with 95% power at α=.05 (2-tailed). The final sample for the analysis included n=59, exceeding the requirement.

Using SPSS Statistics (version 29; IBM Corp), descriptive statistics were applied to analyze the variables under consideration. Means, frequencies, percentages, and SDs were used to describe the data, as well as to answer the first research question (RQ1). Pearson correlations were conducted to assess the relationship between the variables, and a 2-tailed *t* test was performed to examine differences in the continuous variables by the dichotomous variable of sanctions.

The hypothesized regression paths (HP1, HP2, and HP3) were tested using Model 14, a moderated mediation model, of Hayes PROCESS macro in IBM SPSS Statistics (version 29), with 10,000 bootstrap samples [59]. The analysis consisted of a regression test on the effect of responsibility attribution on communication frequency, as well as a test on the role of concern in mediating this relationship at the 2 levels of reported sanctions (ie, no sanctions and presence of sanctions). The mediator (concern) was mean centered prior to analysis. The variable "hours of teaching spent in the classroom" was used as a control variable. The model was tested with the addition of several teacher-level variables (ie, gender and years of experience) but yielded nonsignificant results and deteriorated overall model fit. Therefore, the more parsimonious model was retained. The graphical representation of moderation was performed in R (version 4.5.0; R Foundation for Statistical Computing) using the package *interactions* [60].

Results

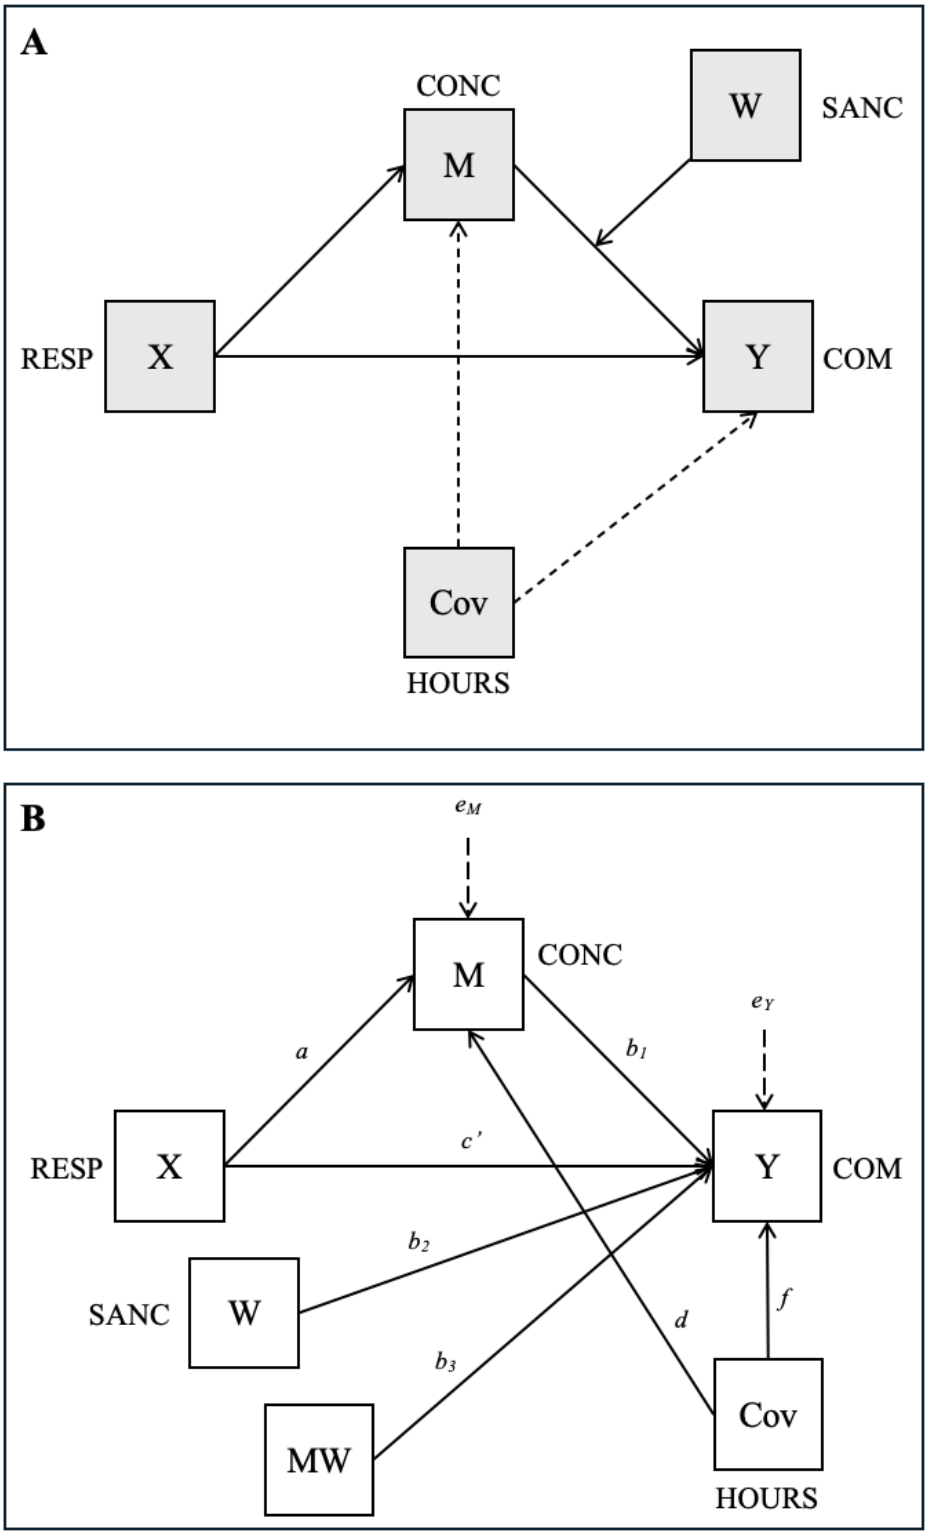
Descriptive Results

Descriptive statistics are reported in Table 1. Following the recommendations of VanderWeele [61], descriptive statistics stratified by sanction level are reported to facilitate interpretation of interaction effects. Correlations and additional information are provided in Table S2 in Multimedia Appendix 1. Information on the variable responsibility attribution will be discussed in the next section, as it directly relates to RQ1. The variable concern had a mean of 2.97, indicating a moderate level of concern for future problems due to smoking. The distribution appears approximately normal, with minimal skewness (0.17) and kurtosis (–0.70). A similar pattern was observed for in-class communication on smoking, for which the mean score was 2.09, reflecting a low to moderate frequency of communication, and the variable appears normally distributed (skewness=0.41 and kurtosis=–0.92). Sanctions were given in 20% (14/67) of cases.

Table 1. Descriptive statistics for continuous variables, stratified by sanctions.

Variable	Frequency, n	Mean (SD)	Range	Sanctions, mean (SD)	
				Yes (n=14)	No (n=53)
Responsibility attribution	65	4.77 (1.07)	3-7	4.43 (0.85)	4.86 (1.12)
Concern	67	2.97 (1.18)	1-5	3.43 (0.94)	2.85 (1.22)
Communication	67	2.09 (0.98)	1-4	2.71 (1.32)	1.92 (0.81)
Hours of teaching (covariate)	61	4.98 (2.10)	0-10	5.46 (2.18)	5.07 (1.86)

Regarding correlations, communication frequency was significantly associated with all variables: it was positively correlated with concern (r=0.25; P<.05) and negatively correlated with responsibility attribution (r=–0.26; P<.05). The independent-samples 2-tailed *t* test revealed a significant difference in communication scores between sanction condition (mean 2.71, SD 1.33) and the no-sanction condition (mean 1.92, SD 0.80); t_{65}=–2.82; and P=.003. Concern and responsibility attribution were not differently distributed in the 2 conditions of sanctions. In other words, higher levels of communication were associated with greater concern, a more internal attribution of responsibility, and the presence of sanctions.



Main Results

Most teachers in the sample (36/67, 54%) attributed a shared responsibility for smoking prevention, and the descriptive statistics offer further insight into this pattern (RQ1). The mean of 4.77 (SD 1.07) suggests that, on average, teachers tend to lean toward attributing more responsibility to parents than to the school, as higher scores reflect external attribution. The distribution is slightly skewed, indicating more teachers score toward the higher end of the scale (Table 1). Notably, no participant attributed full responsibility to the school alone, while 10% (7/67) of participants stated that smoking prevention would solely involve parents.

Using Model 14 of the PROCESS macro [59], it was possible to test the 3 hypotheses. The conceptual and statistical diagrams of the tested model are shown in Figure 2, while the results of the analysis are presented in Table 2. In terms of model fit, a moderate amount of variance was explained, particularly for the outcome variable communication (39%). Controlling for weekly hours of teaching did not change the direction, strength, or significance of the main effects. Both the mediator (M; concern) and the dependent variable (Y; communication) were significantly predicted by the model, as indicated by the respective *P* values.

[b]CONC: concern.

[c]R^2=0.19; $F_{2,56}$=6.71; *P*=.002.

[d]Y: dependent variable.

[e]COM: communication.

[f]R^2=0.39; $F_{5,53}$=6.83; *P*=.001.

[g]X: independent variable.

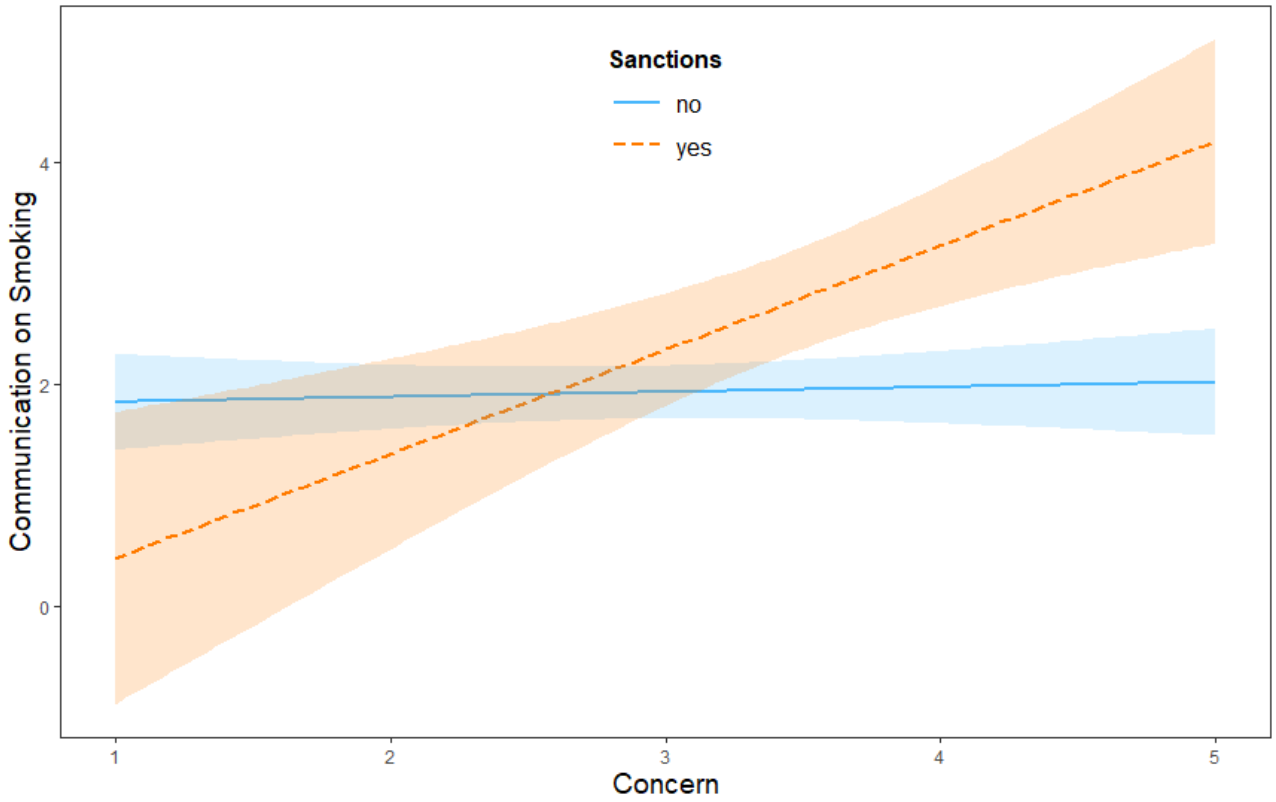
[h]RESP: responsibility attribution.

[i]Not applicable.

[j]W: moderator.

[k]SANC: sanctions.

[l]M × W: interaction effect.



Before delving into hypotheses testing, it is important to note that, because the data are cross-sectional, the directionality of the observed relationships cannot be established. HP1 was supported: the path from responsibility attribution (X) to amount of communication (Y) showed a significant negative direct effect (β=–0.26; *t* value=–2.35, df_1=5, df_2=53; *P*=.02; 95% CI –0.47 to –0.04), even when controlling for concern and interaction effects. The outcome model accounted for a substantial proportion of variance in communication (R^2=0.39; $F_{5,53}$=6.83; *P*=.001). In practical terms, teachers who reported higher scores on responsibility attribution (ie, with an external focus, attributing more responsibility to parents) were also associated with lower rates of in-class discussions on smoking.

The mediation effect (HP2) was not confirmed in the main effect but supported under contextual moderation. As a matter of fact, the effect of responsibility attribution (X) on concern (M) was significant and negative (β=–0.41; *t* value=–3.22, df_1=2, df_2=56; *P*=.002; 95% CI –0.66 to –0.15), indicating that external attribution was associated with lower teacher concern. However, the main effect of concern (M) on in-class communication (Y) was not significant (β=–0.14; *t* value=–1.23, df_1=5, df_2=53; *P*=.22; 95% CI –0.38 to 0.09). In other words, unloading the feeling of responsibility to parents was linked to teachers being worried about the future of their students, but this was not directly associated with a decreased communication effort. Concern alone was not significantly related to communication.

In contrast, HP3 was confirmed: the effect of concern (M) on communication (Y) was indeed moderated by the contextual factor of sanctions (W). The interaction was statistically significant (β=1.01; *t* value=3.74, df_1=5, df_2=53; *P*<.001). When no sanctions were present, the indirect effect was not statistically significant (effect=0.06, 95% CI −0.02 to 0.16). In contrast, when sanctions were present, the indirect effect was significant and negative (effect=−0.35, 95% CI −0.64 to −0.07), indicating that external attribution reduced concern, which in turn reduced communication in sanctioned classrooms. This revealed how concerned teachers talked significantly more in classes where students had been punished for smoking in the previous academic year, compared with students in classes with no sanctions. Further information on the direct and indirect effects is available in Tables S3 and S4 in Multimedia Appendix 1. The indirect effect of responsibility attribution on communication through concern was significant only when past sanctions were present. When no sanctions were applied, the indirect effect was nonsignificant. Practically speaking, when the class had been sanctioned for smoking, the path connecting responsibility attribution to concern and finally to communication was significant (Figure 3).

Figure 3. Graphical representation of the moderation effect on communication.

Discussion

Overview

This study explored the motivational and contextual factors that influence teachers' decisions to engage in classroom discussions about adolescent smoking, using attribution theory as its framework. Before delving into the discussion of the results, it is important to note that this is the first study to investigate the effect of responsibility attribution on communicative behavior. Given the absence of directly comparable studies in the existing literature, this section is primarily devoted to discussing the implications of the findings and proposing avenues for future research.

Findings related to the first research question, regarding whom teachers view as primarily tasked with deterring students from smoking, revealed that teachers generally attribute slightly more responsibility to parents than to the school. Considering parents are still seen by teachers as the reference figures for adolescents, this is not surprising [62]. The result is nevertheless promising and suggests that public efforts to involve teachers in health prevention are well aligned with teachers' perceptions. While teachers do feel slightly less responsible than parents, the difference is minimal. This finding indicates that, in Switzerland, the role of health educator is appropriately positioned in the hands of teachers: they are expected to lead projects on health education and promotion, and several initiatives directly involve them in targeting adolescent populations [63]. Their role in prevention is therefore participatory and includes, but is not limited to, enforcing no-smoking policies in the school perimeter and applying sanctions when rules are broken [64]. The first key finding somewhat reflects this institutional commitment of being involved in children's health prevention. The teachers' feeling of responsibility is expected to vary across health topics, depending on how these issues are addressed in school programs. For example, topics such as sexual or mental health have been more explicitly and widely integrated into curricula through structured programs [65]. Testing their attributions and evaluating their differences when tackling health behaviors is therefore the first main further direction of research to pursue.

The results support the first hypothesis: teachers who attributed greater responsibility to the school (internal attribution) were more likely to communicate with students about smoking. This key finding has both theoretical and practical implications. Theoretically, it establishes the successful use of attribution theory to explain teachers' communicative behavior and supports the idea that perceived responsibility is a key driver of preventive communication [9]. Practically, it highlights the motivational force behind such communication. Considering the model accounts for 39% of the variance, responsibility attribution appears to be a meaningful factor to consider in preventive efforts. A next step would be to examine how parents attribute responsibility and compare their patterns to those of teachers. Questions remain open on situations in which parents' and teachers' perception diverge. Furthermore, exploring adolescents' perspective could offer interesting insights on who they recognize as authoritative and trustworthy figures in health communication. Perceptions of authority and trustworthiness will most likely impact the way adolescents perceive and respond to preventive efforts. In the case of teachers, future research could explore whether increased teacher communication correlates with reduced smoking rates, and

XSL•FO
RenderX

under which relational circumstances this effect is most pronounced.

The relation between attribution and feeling of concern, which is the first part of the mediation process shown in Figure 2A, was confirmed: internal attributions were indeed associated with heightened apprehension about students' future well-being. This finding aligns with the idea that such emotion is a social one: it arises in response to others and is shaped by relational context. Experiencing this form of emotional engagement appears to be a response to perceived responsibility. This supports the first stage of Graham's [9] model, and highlights the potential value of testing other social emotions in future applications, such as pity, guilt, pride, or embarrassment [49,66]. The second hypothesis is, however, only partially confirmed, as concern alone was not significantly linked to communication, suggesting that further contextual clues, such as past sanctions, are needed.

Specifically, the moderated mediation is significant only in the "sanctioned" condition (Figure 2A): concern is associated with communication only when the class has a history of sanctions. Practically speaking, concerned teachers communicated more in classes where students had previously been sanctioned for smoking. This finding is not surprising, as it is reasonable to expect that prevention efforts are more likely to be directed toward students who have already exhibited problematic behavior. In contrast, in classes where smoking is not perceived as an issue, teachers may not feel the need to engage in preventive communication. These results show that classroom dynamics can shape how concern translates into action. The result prompts 2 considerations. First, teachers may not always be fully aware of their students' health behaviors, potentially overlooking those who smoke but have not been caught. Second, reduced communication in such cases may leave students more vulnerable to a future smoking threat. As inoculation theory has demonstrated, consistent communication efforts help protect adolescents from smoking onset [67]. This opens the door to exploring other contextual variables that may shape this relationship, such as school norms or the nature of teacher-parent relationships.

Implications

The research has 2 key implications, 1 related to theory and the other to practice. Theoretically, it successfully applies a psychological theory to the novel field of health communication, identifying attribution theory as a promising framework for studying the drivers of communicative behavior. Communication can be influenced by individuals' responsibility attributions, and this approach is promising because it could be applied to various health-related communication involving multiple actors (eg, parents).

Practically, the findings underscore the vital role of teachers in smoking prevention, positioning them as key figures in adolescents' lives. As previous research has consistently shown, adolescents are shaped by their surroundings—be it their neighborhoods, home environments, or schools—but particularly by the individuals who share these spaces with them [35,68,69]. By actively engaging teachers and empowering them to feel invested in their students' futures, healthier behaviors in adolescents can be fostered.

Limitations and Strengths

This study is not without limitations. First, the sample size of the participating teachers was relatively small, which may limit the statistical power of the findings. However, it is important to note that two-thirds of the schools in the Canton of Ticino were involved and randomly selected—a region that, to begin with, comprises a relatively small number of schools. Among these, the response rate was 66%, which is not low considering the questionnaire was administered at the end of the school year, when teachers were beginning their summer vacation. Second, the use of self-reported data introduces the possibility of social desirability or recall bias. Additionally, variables were measured with single-item scales, due to the constraints of the dataset, as the data analyzed in this study were originally collected for different research purposes. While the use of single-item measures can potentially reduce reliability, their application is not without precedent. Wanous et al [70], in their review of job satisfaction measures, concluded that although multi-item scales are generally preferable, single-item measures may be acceptable when justified by the research context. Furthermore, some items referred also to the school context and not to the individual teacher. We argue, however, that this approach is still valid. Teachers are embedded in the broader context of schools, and their responses likely reflect not only their own behavior but also their perception of institutional practices. Preventive initiatives are often implemented at the school level, and individual teachers' perceptions may be shaped by what their colleagues are doing. The application of multilevel modeling techniques was considered but not implemented due to sample size constraints (ie, limited number of teachers per school). Future research should address this limitation by using larger samples that allow for such modeling.

A further limitation lies in the fact that the study was conducted within the specific sociocultural and educational context of the Canton of Ticino, which may limit the generalizability of the results to other regions or countries. Finally, due to the nature of the cross-sectional data, it is not possible to infer causality or directionality in the model tested.

Despite these limitations, the study offers several notable strengths. It presents a novel application of attribution theory to the field of communication, extending its use into educational settings to explain teacher-student interactions. This theoretical lens provides insights into the motivational drivers behind teachers' communicative efforts regarding adolescent smoking. Moreover, the study draws on a representative sample of schools. Lastly, by focusing on teachers (an often overlooked yet influential population in prevention research), this work contributes to filling an important gap in the literature and opens new directions for theoretical exploration.

Future Directions

This study opens several promising avenues for future research in applying this theoretical framework. First, future research may consider involving a more diverse sample of teachers to examine how variations in role, teaching experience, or

XSL•FO
RenderX

educational context may influence perceived responsibility. A further direction would be to apply attribution of responsibility theory to other health-related topics, such as sexual health, to assess whether the strength or nature of the association differs across issues. To establish causal relationships, the current findings should be replicated using longitudinal data. Finally, the link between attribution of responsibility and communicative behavior could be explored in relation to other key actors, beginning with parents and extending it to the impact on adolescents' behavior, to broaden the scope of this theoretical application.

Conclusions

Let us once again imagine ourselves as teachers facing a classroom of students and talking to them about adverse health behaviors, precisely smoking. According to the results of this study, our level of perceived responsibility will influence our behavior, leading us to speak more frequently with our students when we feel directly responsible for their health. This will happen especially in cases in which concern is high and the class has previously shown issues related to tobacco use.

These findings are particularly significant because they show not only that acting on the perception of responsibility is a valid and effective way to increase classroom conversations about health topics, but also that this theoretical model has the potential to explain communicative behaviors across a range of contexts. A broader assumption of responsibility has the potential to increase communication on sensitive topics and thereby raise awareness on adverse behaviors in the minds of young adolescents.

Abstract

Background: Child abuse is an important issue that threatens child development. The COVID-19 pandemic had psychological, social, and economic effects, and concerns were raised about a possible increase in child maltreatment.

Objective: This study aimed to describe online search trends on child abuse in Japan during the COVID-19 pandemic.

Methods: We conducted a retrospective observational study on the online search volume of terms related to abuse, such as “abuse,” “psychological abuse,” “physical abuse,” “neglect,” “sexual abuse,” “I might become abusive,” “I am scared I might become abusive,” and “I cannot stop abusing,” in Yahoo! Japan. Search volumes were compared with trends in the number of reported cases of COVID-19.

Results: The number of searches for “neglect” increased during periods of social change caused by the COVID-19 pandemic and when waves of the pandemic coincided with the summer vacation period. Searches for terms suggesting abuse, such as “I might become abusive” and “I am scared I might become abusive,” increased in 2020 followed by a decrease from 2021 onward. Most of the searches were conducted by women aged 20 to 49 years.

Conclusions: Online searches related to “neglect” increased during periods of major social change during the COVID-19 pandemic. Searches suggestive of concern about perpetrating abuse were conducted predominantly by women aged 20 to 49 years. Online search data may serve as a useful tool for identifying trends in child abuse–related search interest.

KEYWORDS

abuse; child abuse; COVID-19 pandemic; infodemiology; online search trend

Introduction

The COVID-19 pandemic started with an outbreak of pneumonia of unknown cause in Wuhan, China, in December 2019, eventually reaching Japan. Considerable knowledge has been accumulated on the symptoms of COVID-19, and diagnostic, therapeutic, and preventive methods have been established. However, the COVID-19 pandemic has not only had a devastating negative impact on health but has also had negative psychological, social, and economic effects [1,2], with an increase in the incidence of mental illness, suicide, and abuse of children and older adults [3-7]. Child abuse is a social

XSL•FO
RenderX

problem that requires national countermeasures because of its serious adverse effects on children's mental and physical health and personality development [8].

In Japan, according to Article 2 of the Child Abuse Prevention and Treatment Act, child abuse encompasses not only physical and sexual abuse but also neglect and psychological abuse [9]. According to the Ministry of Health, Labor, and Welfare and the Children and Families Agency, the number of consultations and responses to cases of child abuse has been increasing every year and reached a record high of 225,509 cases in 2023 [9]. The number of cases of abuse may have been underreported during the COVID-19 pandemic owing to school closures and voluntary lockdowns [4,10].

A previous study of online search trends during the COVID-19 pandemic compared the number of searches for "long COVID" with the number of new COVID-19 cases and found that online search trends were associated with real-world events [11]. The online search trends for changes over time in child maltreatment during the COVID-19 pandemic are unclear and, to our knowledge, have not been studied previously. Some studies suggest an increase in child abuse during the pandemic [4,10], whereas other studies suggest a decrease [12]; therefore, the actual situation is unclear.

The purpose of this study was to investigate the trend in online searches on child abuse in Japan and compare it with trends in the number of cases of COVID-19 reported.

Methods

Data Sources

To examine the patterns of online searches on abuse during the COVID-19 pandemic, we obtained data on online searches extracted from Yahoo! Japan, one of the most widely used search engines in Japan. Yahoo! Japan is the most accessed website in the country. According to Japanese data, the total number of accesses was 1.18 billion in November 2021.

Data on the monthly number of abuse-related online searches were available for the period from December 2019 to November 2023. Annual rankings of abuse-related search terms were available up to the top 500 terms for each year from 2019 to 2023.

Search volume data were obtained from Yahoo! Japan Corporation via DS.INSIGHT with legitimate access (last accessed on May 29, 2025). Yahoo! Japan DS.INSIGHT can be accessed by people working at educational and research institutions by obtaining a log-in ID. It is a tool that enables analysis of all Yahoo! Japan big behavioral data, such as keywords, period, gender, age, and prefecture and the transitions and trends in specific searches over time. The user manual is available [13]. The number of internet users in Japan was calculated based on the Communications Usage Trend Survey by the Ministry of Internal Affairs and Communications.

The number of new cases of COVID-19 in Japan was obtained from open access COVID-19 notification data on the Ministry of Health, Labor, and Welfare website. Comprehensive case count data were available only for the period from January 2020 to May 2023.

To compare with the monthly data on online searches related to abuse, the number of new COVID-19 cases was also aggregated on a monthly basis. Monthly search trend data were available for the period from December 2019 to November 2023, and visual comparisons of the monthly number of searches with monthly COVID-19 case counts were conducted from January 2020 to May 2023, the period for which both types of data were available.

Search Queries Used in the Analysis

To investigate the trends in the number of online searches on abuse, we conducted an observational study using the volume of search terms obtained from Yahoo! Japan. We used the search terms "abuse," "psychological abuse," "physical abuse," "neglect," and "sexual abuse" to evaluate online interest in abuse based on monthly data available from December 2019 to November 2023, with the last 4 terms corresponding to the 4 categories of child abuse used on the official website of the Administration for Children and Families under the Law Concerning the Prevention of Child Abuse. In addition, to clarify the trends in the parties conducting searches related to abuse, we analyzed the top 500 search terms including "abuse" in 2020, the year in which the COVID-19 pandemic began, and for each query, we observed the trends for each year from 2019 to 2023 for which top 500 data were available.

Queries related to anticipated or ongoing perpetration of abuse were extracted independently by 2 evaluators (NT and KI), and a third evaluator (MO) also provided an assessment to minimize the effect of observer bias. The search terms "I might become abusive" and "I am scared I might become abusive," which suggest anticipated perpetration of abuse, and "I cannot stop abusing," which suggests perpetrating abuse at the time of the search, were identified. We also identified the query "I have abused"; however, this query was excluded from the main trend analysis because its Japanese equivalent is semantically and temporally ambiguous and may indicate either an abusive act committed in the past with continuity to the present or regret over an abusive act committed in the past without continuity to the present and the annual search volume did not show a clear temporal pattern.

The designation as "Out of ranking," which is shown in the Results section, indicates that a query was not ranked in the top 500 searches for that period and that the search volume was lower than that of the 500th-ranked query.

Statistical Analysis

Details regarding Yahoo! Japan's internal statistical processing were not disclosed owing to concerns that individual data might be identified. Internet users were stratified by age, gender, and year on the day of the search. Categorical variables were summarized as frequencies and percentages. Descriptive statistics were compiled using Microsoft Excel 2019.

Ethical Considerations

This study adhered to Chapter 1, Part 3, Section 1, under category (C), item (iii) of the Ethical Guidelines for Medical

XSL•FO
RenderX

and Biological Research Involving Human Subjects of the Ministry of Health, Labour and Welfare of Japan [14]. In accordance with this guideline, since this study used previously anonymized and de-identified data, an ethical review was waived, and patient informed consent was not required.

Results

Between 2019 and 2023, between 50.3% (49,883,262/99,252,024) and 51% (48,512,132/95,187,232) of all internet users in Japan were men, and the user population was evenly distributed among different age groups (Table 1). The number of online searches related to abuse decreased between 2019 and 2023, with fluctuations from year to year. The gender distribution showed that online searches related to abuse were more commonly conducted by women (40,600/59,200, 68.6%-48,100/66,200, 72.7%) than by men (18,100/66,200, 27.3%-18,600/59,200, 31.4%), and the age distribution showed that the 30- to 49-year age group conducted more online searches related to abuse than other age groups, with 18.2% (10,800/59,200) to 28.1% (32,200/114,600) of searchers aged 30 to 39 years and 22.2% (16,200/73,100) to 24.3% (27,800/114,600) aged 40 to 49 years (Table 1).

Table 1. Number of online searches using the Yahoo! Japan search engine that included the term "abuse" by gender, age, and year (2019 to 2023).

[i]n=99,347,143.

[j]n=59,200.

On visual comparison of monthly trends, no clear relationship was apparent between the number of new COVID-19 cases and the search volume for "abuse," "psychological abuse," "physical abuse," "neglect," and "sexual abuse"; however, the number of searches for "neglect" increased during the early phase of the COVID-19 pandemic (from March 2020 to August 2020), the fifth wave (June to November 2021), and the seventh wave (June to October 2022). During the study period, the number of new COVID-19 cases increased from year to year, but the number of searches for "neglect" did not (Figure 1).

XSL•FO
RenderX

Figure 1. Monthly number of new COVID-19 cases (January 2020 to May 2023) and monthly search volume using the terms “abuse,” “psychological abuse,” “neglect,” “physical abuse,” and “sexual abuse” (December 2019 to November 2023). On May 8, 2023, the Japanese government reclassified COVID-19 as a class 5 infectious disease according to the Infectious Diseases Control Law, placing it on the same level as seasonal influenza and syphilis.

Next, we extracted data on searches that suggested perpetration of abuse and found that the search volume for “I might become abusive” increased from 1300 in 2019 to 1500 in 2020 (a 15.4% increase) and then decreased to 1100 in 2021 (a 26.7% decrease from 2020). For “I am scared I might become abusive,” the exact 2019 search volume was unavailable because the term was reported as out of ranking (≤410 searches); therefore, a percentage change could not be calculated. However, the search volume was 460 in 2020, indicating that the number of searches for this term also increased from 2019 to 2020. It then decreased to 310 in 2021 (a 32.6% decrease from 2020). Women accounted for 94% and 96% of those searching for “I might become abusive” and “I am scared I might become abusive,” respectively, in 2020, and internet users aged 20 to 49 years accounted for 96% and 89% of those searching for “I might become abusive” and “I am scared I might become abusive,” respectively, in 2020 (Table 2). Of those searching for “I cannot stop abusing,” suggesting ongoing abuse, women accounted for 88% of the searchers by gender, and internet users aged 20 to 49 years accounted for 92% of searchers by age. The annual number of online searches for “I cannot stop abusing” decreased by 12.6% in 2020 compared with 2019 and by 6% in 2021 compared with 2020, indicating a decrease in the number of searches conducted during the COVID-19 pandemic.

XSL•FO
RenderX

Table 2. Number of searches related to committing abuse by gender, age, and year (2019 to 2023). Since Yahoo! Japan uses expanded statistics, this table lists only the total number of searches and the percentage.

Discussion

Principal Findings

To contribute to the understanding of the epidemiology of child abuse in Japan, this study characterized the trends in online searches related to child abuse during the COVID-19 pandemic.

According to information on the Administration for Children and Families website, the number of consultations on child abuse at Child Guidance Centers in Japan has been increasing each year; however, this increase was not reflected in the number of online searches related to child abuse during the 5-year study period. Furthermore, the number of searches for "psychological abuse," which accounted for 59.6% of all consultations on child abuse at Child Guidance Centers in 2022 (according to information on the Administration for Children and Families website), was small, whereas the number of searches for "neglect," which accounted for only 16.2% of all consultations on child abuse at Child Guidance Centers in 2022, was the largest of the 4 child abuse categories considered, showing a discrepancy between the number of consultations related to specific types of child abuse and the volume of online searches for the corresponding type of abuse. Possible reasons for this discrepancy may be that online searches are influenced by news reports of prominent cases and that online searches include searches for cases that are not clearly abusive because the general perception of what constitutes abuse among internet users is broader than the legal definition of abuse. In this study, on visual comparison of monthly trends, no clear relationship was apparent between the number of new COVID-19 cases and the search volumes for the terms "abuse," "psychological abuse," "physical abuse," "neglect," and "sexual abuse."

XSL•FO
RenderX

The observed increase in searches for "neglect" may be interpreted in the context of social changes during the COVID-19 pandemic. Previous studies have identified economic factors, mental and physical health problems of parents and children, and parenting stress as risk factors for neglect [15]. The COVID-19 pandemic led to increased parenting burden owing to parents' economic difficulties, worsening mental health, and social isolation [16-19]. Previous studies on child abuse during the COVID-19 pandemic have reported mixed findings [20], and no consistent trend has been established for specific types of abuse. Although this has not been a conclusion consistently supported across the existing literature, some studies have suggested an increase in the incidence of neglect [21,22].

In Japan, during the period of voluntary curfew, worsening of physical and mental symptoms was especially noticeable among young adults aged 18 to 29 years; women; people with a history of treatment for mental illness; and people with socially disadvantaged backgrounds, including those with an annual income of less than ¥2 million (US $12,400; ¥1=US $0.0062 as of June 8, 2026) [23]. In another study of pregnant women and mothers less than a year post partum conducted during the COVID-19 pandemic [24], 38% reported "decreased income," 77.2% reported "fear of COVID-19," and 18.1% reported "experiencing criticism for taking my child to a public place." Of these, "decreased income" and "experiencing criticism for taking my child to a public place" were associated with a higher risk of perinatal depression [24]. These prior findings suggest that some factors associated with neglect may have worsened during the COVID-19 pandemic, providing a possible context for interpreting the observed increase in neglect-related searches.

In Japan, COVID-19 began to have an impact on daily life in March 2020. All elementary, junior high, and high schools in Japan were temporarily closed during spring break starting on March 2, 2020, and on April 7, 2020, a state of emergency was declared, requiring voluntary restraint from going out and holding events and restricting the use of facilities, which changed the way of life. The state of emergency was lifted on May 25, 2020, and the restrictions were gradually lifted in June 2020, but the number of cases of COVID-19 began to increase, leading directly to the second wave. The number of searches for "neglect" gradually increased starting in March 2020 followed by a decrease starting in August 2020, when the second wave began to subside. During the fifth wave (June to November 2021) and the seventh wave (June to October 2022), the number of searches for "neglect" increased markedly and then decreased as the number of new COVID-19 cases declined. Both the fifth and seventh waves occurred during the summer vacation period in Japan. During school vacations and natural disasters, children are isolated from their communities and schools, and programs to prevent child abuse are canceled; therefore, abuse is less likely to be reported despite an increased incidence [25,26]. Nevertheless, the results of this study show that online interest in "neglect" increased even during such periods.

During the seventh wave, the number of new cases of COVID-19 was higher than that during the fifth wave, but the number of online searches using the term "neglect" was lower. Changes between the fifth and seventh waves included a shift from the Delta variant to the less virulent Omicron variant and the holding of traditional festivals in various parts of Japan for the first time in 3 years, which eased the mood of self-restraint and led to a recovery in socioeconomic activities. Furthermore, in September 2022, the government introduced a shortened isolation period for individuals with COVID-19. After the eighth wave, on visual comparison, the number of searches for "neglect" did not appear to increase to the same extent as that observed during the early phase of the COVID-19 pandemic and during the fifth and seventh waves.

With each successive lockdown in Japan, the tendency for exacerbation of physical and mental symptoms was less marked owing to adaptation to the environmental changes brought about by the COVID-19 pandemic [23]. This study demonstrates that, although the annual number of new COVID-19 cases increased from thousands in 2020 to hundreds of thousands in 2022, the number of searches for "neglect" did not show a corresponding increase. Although the number of searches for "neglect" was not proportional to the number of new cases of COVID-19, the number of searches for "neglect" increased during periods of changes in living environments due to the COVID-19 pandemic, such as during the period of state emergency declarations and measures to prevent the spread of the disease and summer vacation periods coinciding with the COVID-19 pandemic waves.

These results are consistent with those of previous studies [15-19] that identified economic factors, mental and physical health problems of parents and children, and parenting stress as risk factors for neglect, all of which were amplified during the COVID-19 pandemic.

As searches for "abuse," "psychological abuse," "physical abuse," "neglect," and "sexual abuse" include searches from searchers with diverse intentions, we investigated searches that may reflect concern about potential or ongoing perpetration of abuse taking advantage of the anonymity of online searches.

We focused on searches from 2020 to 2021, the period immediately after the onset of the COVID-19 pandemic, and found that the number of searches for "I might become abusive" and "I am scared I might become abusive," which may reflect concern about potential perpetration of abuse, increased in 2020 and decreased in 2021 compared with 2019 and 2020, respectively. These searches were mainly conducted by women in their 20s to 40s, an age group likely to include mothers. In 2020, shortly after the onset of the COVID-19 pandemic, when lifestyle changes were most marked, the number of searches on the fear of perpetrating abuse increased the most among young adults, the age group most likely to include parents of young children.

According to the surveys conducted by the Japan Institute for Labor Policy and Training in 2012 and 2014, a total of 12% of mothers in Japan are worried that they may be abusing their children even during normal times, and 40.5% of those who worry about being abusive engage in excessive physical punishment or neglect [27]. These tendencies may have intensified in 2020. However, searches for "I cannot stop abusing," which suggests ongoing abuse-related concern at the time of the search, were predominantly by women aged 20 to 49 years, an age group likely to include mothers, but the increase

XSL•FO
RenderX

did not correspond to the COVID-19 restrictions or to waves of the COVID-19 pandemic. On the basis of these findings, we assume that, at the onset of the COVID-19 pandemic in 2020, which led to marked changes in lifestyle, the number of women aged 20 to 49 years who searched for terms suggesting concern about becoming perpetrators of abuse increased, whereas searches suggesting ongoing abuse did not show a corresponding increase. However, based on these results, the possibility of changes in the degree or type of abuse during the COVID-19 pandemic cannot be ruled out.

This study found that the internet was also a means of accessing information for women in their 20s to 40s, an age group that may include mothers, who were concerned about perpetrating abuse. According to the World Health Organization handbook on measuring and monitoring national prevalence of child maltreatment, the results of surveys of parents regarding abuse are influenced by denial of socially undesirable behavior, leading to underreporting and inconsistencies with surveys of children; therefore, anonymity in fact-finding surveys is important [28]. Because anonymity is ensured, monitoring online search trends may be a useful tool for understanding changes in online interest in or concern about abuse-related issues during a pandemic.

Limitations

This study has several limitations. First, Yahoo! Japan was the sole data source, and online searches conducted using other search engines were not considered; therefore, the results may not be generalizable beyond the specific population from which the sample was drawn. Second, data obtained from online search engines may be subject to nonrepresentative sampling and methodological biases specific to search platforms. Third, no consideration was given to other factors that affect online interest in abuse, such as large media coverage, school closures, seasonal factors, and broader help-seeking behavior, because this was not possible. Fourth, the available data were limited in temporal scope, and comparisons across data sources were restricted to the period in which they overlapped. Fifth, annual rankings of abuse-related search terms were available only for the top 500 terms for each year, which limited the ability to follow some terms continuously across the 5-year study period. Furthermore, potentially relevant but less frequently searched terms may have been excluded.

Conclusions

On visual comparison, the observed increase in searches for the term “neglect” during the COVID-19 pandemic may be interpreted in the context of social changes during this period. Although no direct causal relationship could be established, this pattern may reflect the influence of factors identified in previous studies, including psychosocial stress, economic hardship, and social isolation. Previous studies have shown that, during school vacations and natural disasters, children are more isolated from society, making reporting of abuse less likely, but online interest in neglect increased during school vacations and during periods coinciding with waves of the COVID-19 pandemic. In addition, searches by women in their 20s to 40s, an age group that may include mothers, suggesting concern about perpetrating abuse also showed an increase in 2020 at the onset of the COVID-19 pandemic. Monitoring online search data is useful for understanding patterns of online interest in abuse as such searches can be conducted anonymously.

Abstract

Background: Autism spectrum disorder (ASD) not only affects a person's social communication and behaviors, but also has an impact on their parents, who encounter different challenges during caregiving. Interventions developed for parents of children with ASD often focus on improving child outcomes and seldom consider the well-being of parents and families. Interventions leveraging mindfulness-based approaches have been developed to support parents of children with ASD, but the costs, inflexibility, and scarcity of resources may limit their accessibility. App-based interventions can be an accessible, scalable, and economical way of providing interventions at a primary health care level.

Objective: The aim of this study was to develop an evidence-based digital intervention that complements existing, overloaded psychiatric services, to provide mindfulness-based psychoeducation for parents of children with ASD to improve their mental well-being.

Methods: The app development process follows the systematic approach of intervention mapping. Needs assessment was first conducted through semistructured qualitative interviews with health care professionals. Performance and change objectives were specified; theory-based and practical application methods were selected, followed by the design of the curriculum for a structured intervention. A pilot waitlist randomized controlled trial was conducted to evaluate the feasibility, acceptability, and preliminary efficacy of the app with parents of children with ASD recruited from a tertiary child psychiatric service in Hong Kong.

Results: The resulting intervention, the TRIP app, is a 6-week structured intervention consisting of 6 sessions per week (each session lasting 15 - 20 minutes), covering topics on ASD parenting skills and mindfulness practices. The six weekly themes include (1) cultivating curiosity in parenting, (2) mindfulness of the breath and body, (3) management of core and associated features of ASD, (4) managing conflicts and setting boundaries, (5) perspective taking, and (6) cultivating self-compassion. The curriculum was designed to target the determinants of parental stress, including parents' knowledge, skills, emotions, and attitudes. App content and features were designed to incorporate behavioral change techniques, social cognitive theory, and elaboration likelihood model, to enhance efficacy and promote long-term usage. The app was found to be feasible and acceptable in the pilot randomized controlled trial (n=40), with greater long-term usage among parents of children on the waiting list who were yet to receive diagnostic assessment and clinical management, when compared with parents of children who have already been receiving clinical care.

Conclusions: The TRIP app was developed based on knowledge and expertise across psychiatry, public health, behavioral science, and implementation science. It caters to the unmet needs for improving caregiver well-being in the holistic care model for families of children with ASD. The clinical efficacy of the TRIP app is yet to be evaluated through clinical trials.

Introduction

Autism spectrum disorder (ASD) is a neurodevelopmental disorder that can affect individuals throughout their lifetime, as persistent deficits and behavioral challenges can lead to functional impairments [1], and may also have a vast impact on their parents and families. Current interventions for ASD are primarily focused on improving adaptive functioning and ameliorating maladaptive behaviors [2], often comprising a combination of behavioral interventions, social communication training, and sensorimotor therapy. The delivery of these interventions is often brief and infrequent, limited by both the capacity of health service providers and the costs of the interventions. As a result, parents and caregivers inevitably take on a role in delivering interventions. Parent training programs (eg, the widely known Triple P Positive Parenting Program [3] and the Incredible Years Parent Training program [4]) were adapted to equip parents of children with ASD with the required skills for independent implementation of interventions with minimal or no support from therapists. While parent training for ASD is effective in improving child development [3,5,6], most of these trainings focused on improving children's behaviors and functioning, with a lack of emphasis on alleviating parental stress or enhancing their mental well-being and quality of life. As parents tend to shoulder a great deal of stress with limited professional support, taking care of parents' own mental well-being is essential when supporting parents in implementing interventions for their children [7].

In terms of the approaches used in interventions developed for supporting parents, mindfulness-based interventions (MBIs) were found to have positive effects in reducing parental stress and depressive symptoms and improving psychological well-being in parents of children with ASD [8,9]. Interventions tailored to integrate mindfulness into parenting for ASD have been developed, such as the Mindful Parenting program, which has the following aims: (1) to reduce parental stress, negative bias, and reactivity; (2) to break the cycle of intergenerational continuity of maladaptive parenting; (3) to promote self-nourishing attention and self-compassion; (4) to improve marital relationships, functioning, co-parenting; and (5) to reduce interparental conflicts [10]. The Mindful Parenting program was later extended into the MYmind program for ASD, delivering parallel, concomitant mindfulness training for adolescents with ASD and their parents, which was found to improve parenting style and competence, and increase quality of life for both adolescents and their parents [11].

Although MBIs have promising outcomes, the fixed 8-week structure of the courses may not fit into parents' busy schedules and could be costly, especially for families of lower socioeconomic status. App-based interventions can overcome these barriers and provide an accessible, flexible, and affordable platform for education and lifestyle changes. Furthermore, digital platforms can enable easier and quicker access to intervention content. Prompts through navigation, notification, and gamification can also encourage access to content compared with traditional web-based interventions [12]. A recent meta-analysis demonstrated that app-based mindfulness interventions were efficacious in reducing perceived stress and improving symptoms of depression and anxiety across diverse samples, including the general adult population and clinical populations suffering from major medical illnesses [13]. Some randomized controlled trials (RCTs) even showed comparable effects between app-based and face-to-face interventions [14]. Recent studies also found that app-based mindfulness interventions were effective for parents, as studies reported improvements in mindful parenting in the general population [15] and increased positive parent-child interactions and reduced parenting stress among parents of children with ASD [16]. Therefore, app-based interventions can be an accessible and economical way of providing a feasible alternative to in-person interventions for improving parental well-being.

While the market is not deprived of generic smartphone apps for improving mental health or mindfulness, attrition and non-adherence are common in unguided app-based interventions [17,18]. As app-based interventions were found to be more efficacious when complementing current care and being customized to users' goals and needs [19], tailored content is a crucial element in maintaining motivation for continual use. To date, the only app-based intervention developed for parents of children with ASD is the Smartautism app, a mobile app developed in France that uses ecological momentary assessment (EMA) to provide feedback for parents of children with ASD (aged 3 - 16 y) to adapt parents' educational behavior between medical appointments [20,21], and no app-based interventions have been developed for delivering MBIs tailored for parents of children with ASD. Therefore, considering the limited resources and inadequate provision in public health care for ASD, the aim of this study was to develop an app for mindfulness-based psychoeducation for parents and caregivers of children with ASD, and to evaluate the feasibility, acceptability, and preliminary efficacy of the app. Specifically, while the prevalence of ASD in Hong Kong is comparable to that of Western countries [22], clinical services for ASD in Hong Kong have seen a rapid increase in attendance by 162% over the past decade, with a 3-fold increase in average waiting time from 23 weeks in 2012 - 2013 to 80 weeks in 2019 - 2020 [23]. As such, we would like to explore whether the preliminary efficacy of the app is different for parents of children who were still on the waiting list to be seen by a psychiatrist for diagnostic assessments and clinical management, and hence are receiving lower levels of care and support when compared with parents of children who have already been receiving clinical care.

Methods

Overview

The app development process follows a systematic, evidence-informed approach according to intervention mapping (IM) [24,25], a protocol for intervention development that fulfills the UK Medical Research Council framework for developing complex health care interventions [26]. IM is an iterative, 6-step method that is well-established and widely used (Figure 1). This article focuses on reporting the results of steps 1 - 4 of the IM process, including the development and usability testing of the app. Steps 5 - 6, which involve intervention implementation and evaluation, are planned but will be reported separately when completed. This report follows the Consolidated Standards of Reporting Trials of Electronic and Mobile Health Applications and Online Telehealth (CONSORT-EHEALTH) checklist (V.1.6.1).

Figure 1. Systematic development of the TRIP app using intervention mapping. RCT: randomized controlled trial; RE-AIM: Reach, Effectiveness, Adoption, Implementation, and Maintenance.

Ethical Considerations

Ethical approval was obtained from The Joint Clinical Research Ethics Committee established by The Chinese University of Hong Kong and New Territories East Cluster (qualitative study in step 1: Ref 2021.591; pilot RCT in step 4: 2022.586). Informed consent was obtained from all participants according to the Declaration of Helsinki. Data were anonymized and securely stored to ensure participant confidentiality. Upon the completion of the study, health care professionals in step 1 did not receive any financial compensation, whereas parents in step 4 received vouchers valued at HKD $100 (approximately US $12.50).

Step 1: Needs Assessment

The needs of parents and caregivers of children with ASD were assessed through an explorative qualitative study conducted with health care professionals to understand the underlying sources of challenges faced by ASD caregivers and recommendations to support parents in overcoming these

XSL•FO
RenderX

challenges, complementing the lived experiences of parents and families that are already well-documented in the literature. Health care professionals providing tertiary specialist clinical services for ASD were purposively sampled via referral by professional acquaintances, and the sample size was guided by the principle of information power [27]. Semistructured interviews were conducted according to an interview guide developed with input from psychiatrists based on clinical experiences (Multimedia Appendix 1). Topics included management of ASD symptoms, impact of ASD on family dynamics, experiences of stigma around ASD, and responses toward the diagnosis. Open-ended questions and supplementary probing were used to allow any explorative, spontaneous, and in-depth discussions that may emerge during the conversation [28]. Interviews were first transcribed verbatim and checked for accuracy. Qualitative data then underwent inductive coding [29,30]. Codes were then mapped onto an adapted social ecological model (SEM), which considers multiple levels of influence on health and well-being, including individual, interpersonal, institutional, community, and societal levels [31]. Codes were then compiled to create a logic model based on the PRECEDE model (ie, Predisposing, Reinforcing, and Enabling Constructs in Educational Diagnosis and Evaluation), which provides a comprehensive framework for assessing the different determinants of health through an educational diagnosis before developing and implementing interventions for health promotion [32]. The PRECEDE model comprises 4 phases, beginning with a social assessment, followed by an epidemiological assessment, a behavioral and environmental assessment, and an educational and ecological assessment. Detailed methods and findings from the subsequent thematic analysis of this qualitative study were published separately [33].

Step 2: Matrices of Change Objectives

Based on the results from step 1, intervention outcomes and relevant, modifiable behavioral determinants were identified. This was used for specifying the performance objectives, which are specific actions required to achieve the intervention outcome. A matrix of change objectives was then created, which specifically identifies behaviors or thought processes that needed to be changed in order to achieve the target outcomes.

Step 3: Theory-Based Methods and Practical Applications

Theory-based methods and practical applications were selected to achieve behavior change in parents and caregivers of children with ASD. As there is considerable evidence in the existing literature for the effectiveness of MBIs in supporting ASD caregivers, mindfulness was selected as the basis for content development. The elaboration likelihood model (ELM) [34], which posits a dual process theory of attitude change through central and peripheral processing requiring varying levels of cognitive efforts, was selected as the basis for curriculum development. The social cognitive theory (SCT) [35], which suggests that people can learn to change, achieve, and maintain goal-directed behaviors over time through different constructs, including behavioral capability, outcome expectations, observational learning, self-efficacy, and reinforcements, was selected as the basis for the design of app content and features. Behavior change techniques (BCTs) based on an extensive taxonomy of 93 distinct techniques across 16 different group categories by Michie and colleagues [36] were mapped onto different SCT constructs for practical application to target specific change objectives.

Step 4: Program Development

App Development and Evaluation Process

The digital intervention was developed by a collaborative team of researchers, psychiatrists, mindfulness experts, software engineers, graphic designers, and text editors. The app development process involves the parallel, iterative development of app curriculum and content, content production and refinement, and software design and development. App curriculum and content were developed through 10 co-design sessions (each lasting around an hour) with an experienced mindfulness teacher (EWYW), a child psychiatrist (OWHW), an adult psychiatrist (SSMC), a doctoral researcher with a psychology background (KKYM), and our project manager (OC). Co-design sessions were structured according to the design thinking framework [37], with a focus on iterative cycles of define, ideate, and prototyping for the design of the app curriculum and content. Content production and refinement was done in collaboration with a text editor for editing and proofreading, a mindfulness expert for audio recording of mindfulness practices and voice-over narrations for animations, and a graphic designer for illustrations and animations. Software design and development was actualized by software engineers and graphic designers, respectively. The prototype of the app underwent alpha and beta testing with health care professionals and parents before it was officially launched. A prospectively registered pilot waitlist-RCT [38] was then conducted to evaluate the feasibility, acceptability, and preliminary efficacy of the app. This was followed by an ongoing large-scale RCT for evaluating the efficacy of the app (n=700) [39], which will be reported separately when the trial is completed.

Participant Recruitment

Participants were 40 parents or caregivers of children with ASD (aged ≤12 y) diagnosed by clinicians according to the *DSM-5* (*Diagnostic and Statistical Manual of Mental Disorders* [Fifth Edition]) criteria [40]. Only parents who can understand spoken instructions in Cantonese and texts written in traditional Chinese were eligible. Parents who were not primary caregivers, or those currently receiving psychological interventions or undergoing mindfulness training, were excluded. Participants were recruited from a university-affiliated tertiary hospital providing the sole public child and adolescent psychiatric service in a region of >1.2 million population in Hong Kong. In the clinic, parents were recruited from either the triage service (where the child had gone through initial triage assessment by nurses but were still on the waiting list to be seen by a psychiatrist for diagnostic assessments and clinical management), or the psychiatrist-led clinic (where ASD diagnosis was already made and the child was receiving active treatment and training from the hospital), therefore representing 2 different groups of parents whose children were receiving different levels of care and support.

XSL•FO
RenderX

Potential participants were approached individually in a short call via videoconferencing, where they were given information about the study and had their questions addressed. Eligibility of interested participants was screened through a brief screener survey. Written informed consent was obtained from all eligible participants who agreed to participate. Participants were randomly allocated to either the immediate intervention group or the waitlist-control group, using the Qualtrics randomizer with a 1:1 allocation ratio through stratified block randomization (block sizes of 4, stratified according to the level of support received [waiting list vs clinical care] and child age [≤6 y, 7-9 y, and 10 - 12 y]). Participants in both groups received the intervention: the intervention group received the intervention immediately after allocation, whereas the control group received the intervention after 6 weeks of treatment as usual.

Sociodemographic and Clinical Characteristics

Sociodemographic information (including parents' sex, age, and educational level, and child's sex and age) and clinical characteristics were obtained at baseline. Child clinical characteristics were considered by parent-reported measures, including the Social Responsiveness Scale, second edition (SRS-2) for ASD core symptoms [41], as well as the Anxiety Scale for Children-ASD questionnaire [42] and the externalizing and attention problems subscales of the Child Behavior Checklist (CBCL-Ext and CBCL-Attn) [43] for common co-occurring psychopathology. Age-appropriate versions of SRS-2 and CBCL were used for preschool and school-aged children, respectively.

Outcome Measures

The primary outcomes of the pilot study were feasibility and acceptability of the app. Feasibility was measured by app usage during the intervention period, including usage patterns (day of week and time of day), user engagement (number of usage days, number of logins, and time spent per day), program participation (number of sessions completed and curriculum completion rate), and retention rates in terms of current use (participants who used the app during a given week) and last use (the last time the app was used by participants). Acceptability was assessed immediately post intervention by the 10-item System Usability Scale (SUS-10) [44], assessing the usability of products and apps, and the 20-item User Version of the Mobile Application Rating Scale (uMARS) [45], measuring engagement, functionality, aesthetics, and information quality of health apps.

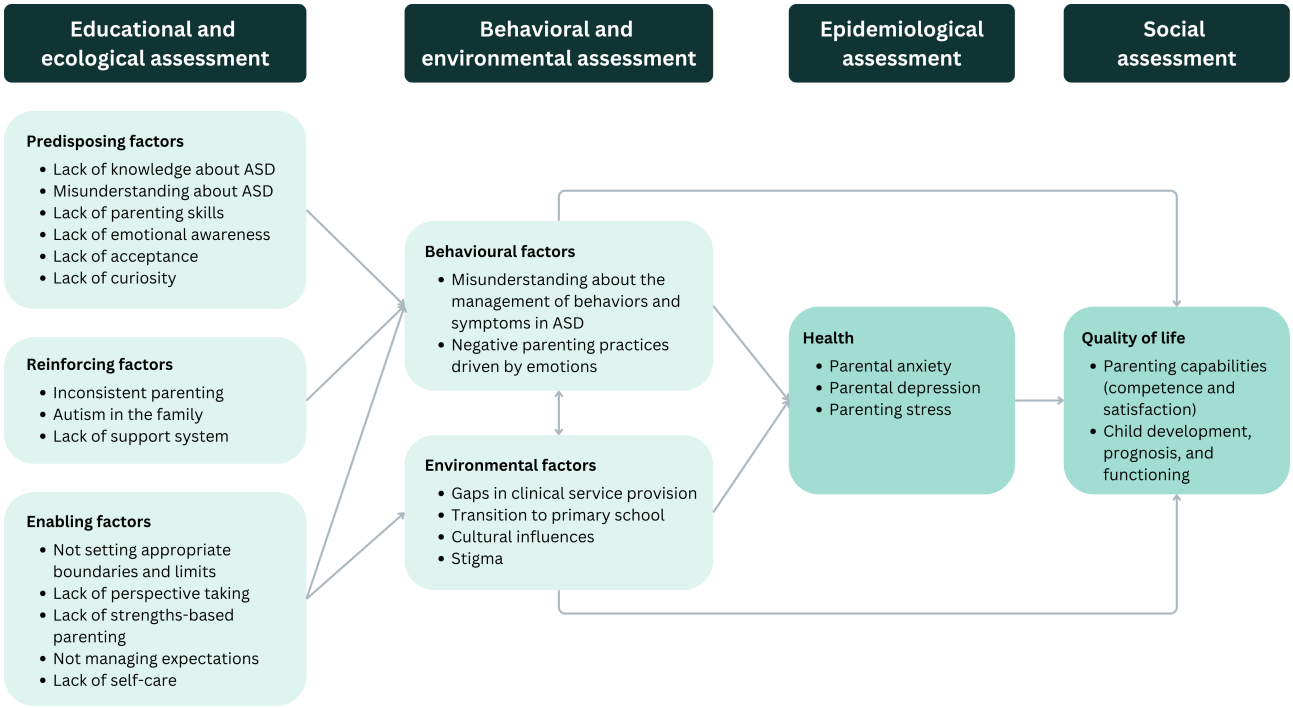
The secondary outcome was preliminary efficacy, including parental mental health, parenting capabilities, and levels of mindfulness measured at baseline, preintervention, postintervention, and at 2-month follow-up. The selection of outcome measures was informed by the social and epidemiological assessment in step 1. Parental mental health was assessed by the 7-item General Anxiety Disorder scale (GAD-7) [46] and the 9-item Patient Health Questionnaire (PHQ-9) [47], and parenting stress was measured by the 36-item Parenting Stress Index-Short Form (PSI-SF) [48]. Parenting capabilities were considered in terms of parenting competence and satisfaction, which were measured by the 17-item Parenting Sense of Competence scale (PSOC) [49], the 6-item parenting efficacy subscale of the Parenting Self-Agency measure (PSA-PE) [50], and the 7-item warmth subscale of the Parenting Styles and Dimensions Questionnaire (PSDQ-W) [51]. Levels of mindfulness were assessed by the 15-item Mindful Attention Awareness Scale (MAAS) [52,53] and the 31-item Interpersonal Mindfulness in Parenting questionnaire (IM-P) [54,55].

Statistical Analysis

Analysis of covariance (adjusting for baseline values) was used to investigate the intervention effect and outcome changes from preintervention. Analyses were conducted according to the intention-to-treat principle, with last observation carried forward for any missing data. Analyses were stratified by the source of recruitment (triage service or psychiatrist-led clinic), as this represents different levels of support received by parents of children with ASD (waiting list vs clinical care). Intervention effect on all efficacy outcomes was analyzed separately with the same procedures, with outcome scores as the dependent variable, randomization group as a factor, and baseline values of the outcome and child clinical characteristics (SRS-2 and CBCL-Ext) as covariates (based on previous findings from the literature [56,57]). A similar procedure was used to compare changes in outcomes from preintervention to postintervention and 2-month follow-up, with assessment timepoint as a factor, and adjusting for preintervention value of the outcome, child clinical characteristics at baseline (SRS-2 and CBCL-Ext), and randomization group, to account for any potential confounding effects in intervention participation as a result of delayed intervention [58]. All analyses were performed in jamovi (version 2.6.2; The jamovi project) [59].

Results

Step 1: Needs Assessment



We conducted 10 interviews, including 7 individual interviews and 3 group interviews, with 16 health care professionals working in different roles, including psychiatrists (n=2), psychiatric nurses (n=9), clinical psychologists (n=2), an occupational therapist (n=1), a hospital-based teacher (n=1), and a social worker (n=1). We identified 4 key areas at the individual level of the SEM where parents faced challenges during caregiving, namely knowledge, skills, emotions, and attitudes. The key caregiving skills needed were broadly categorized into skills for managing specific child behaviors, skills during daily interactions with children, and skills for self-care. Moreover, health care professionals also shared their perspectives on wider contextual and environmental factors within the SEM that pose challenges for parents when caring for children with ASD. These include interpersonal factors such as inconsistent parenting and autism in the family, institutional factors such as the transition from kindergarten to primary school and gaps in clinical service provision, community factors such as support systems and cultural influences, and societal factors related to stigma surrounding ASD. Detailed codes and examples are provided in Multimedia Appendix 2. Detailed findings from the subsequent thematic analysis of this qualitative study were published separately [33].

Figure 2 shows a logic model for caregiver challenges faced by parents of children with ASD. Social assessment identified aspects of quality of life impacted by caregiving for ASD,

XSL•FO
RenderX

including parenting competence and satisfaction, and children's development, prognosis, and functioning. Epidemiological assessment suggested that caregiver challenges affect parents' health through parenting stress, anxiety, and depression. Parallel analyses of behavioral and environmental factors revealed that misunderstanding about the management of behaviors and symptoms and negative parenting practices driven by emotions were the main challenges faced by parents, which were influenced by various environmental factors, including service gap, school transitions, cultural influences, and stigma. Educational and ecological diagnosis identified the main needs of parents in terms of predisposing factors related to parents' knowledge, skills, attitudes, and emotions, reinforcing factors in parents' social environment, and enabling factors related to varying levels of relational skills for parenting.

Figure 2. Logic model for caregiver challenges faced by parents of children with autism spectrum disorder. ASD: autism spectrum disorder.

Step 2: Matrices of Change Objectives

Based on the findings from the needs assessment in step 1, the overall intervention outcome was to reduce parental stress, anxiety, and depression, whereas the behavioral outcome was to improve parents' management of children's behaviors and symptoms. The specific performance objectives for the behavioral outcome were to (1) improve parents' understanding of behaviors and symptoms, and (2) improve parents' emotional regulation. A matrix of change objectives for parents of children with ASD based on the specific performance objectives is presented in Table 1.

XSL•FO
RenderX

Table . Matrix of change objectives for parents of children with ASD[a].

Performance objectives	Change objectives categorized by determinants[b]			
	Knowledge	Skills	Emotions	Attitudes
To improve parents' understanding of behaviors and symptoms	• Improve knowledge about ASD around sensory issues and academic abilities (1.1.1) • Address misunderstandings about ASD related to social communication, repetitive behaviors, emotional expression, and comorbidity (1.1.2) • Learn about specific skills for toilet training, communication skills training, and organizing play (1.1.3)	• Use effective instructions and commands when parenting (1.2.1) • Avoid misconstrued behavioral reinforcement and encourage parents to make use of children's stereotyped interests (1.2.2) • Adopt an investigative mindset during parent-child interactions and take children's perspective to understand their underlying intentions and motivations for their behaviors (1.2.3)	• Avoid emotionally-charged parenting, especially when trying to understand children's behaviors (1.3.1)	• Increase curiosity in children's behaviors and characteristics (1.4.1)
To improve parents' emotional regulation	• Understand the negative effects of unhelpful parenting practices on the parent-child relationship and children's development (2.1.1) • Understand how inconsistent parenting can be confusing and unhelpful for children (2.1.2)	• Avoid emotionally-charged parenting and other negative parenting practices and adopt strengths-based parenting (2.2.1) • Manage own expectations about children's progress and development (2.2.2) • Balance between showing love and setting limits (2.2.3) • Reserve time for self-care through cultivating parents' own interests and hobbies (2.2.4)	• Improve emotional awareness (2.3.1) • Increase self-compassion (2.3.2)	• Acknowledge the presence of ASD diagnosis (2.4.1) • Increase acceptance toward ASD (2.4.2)

[a]ASD: autism spectrum disorder.

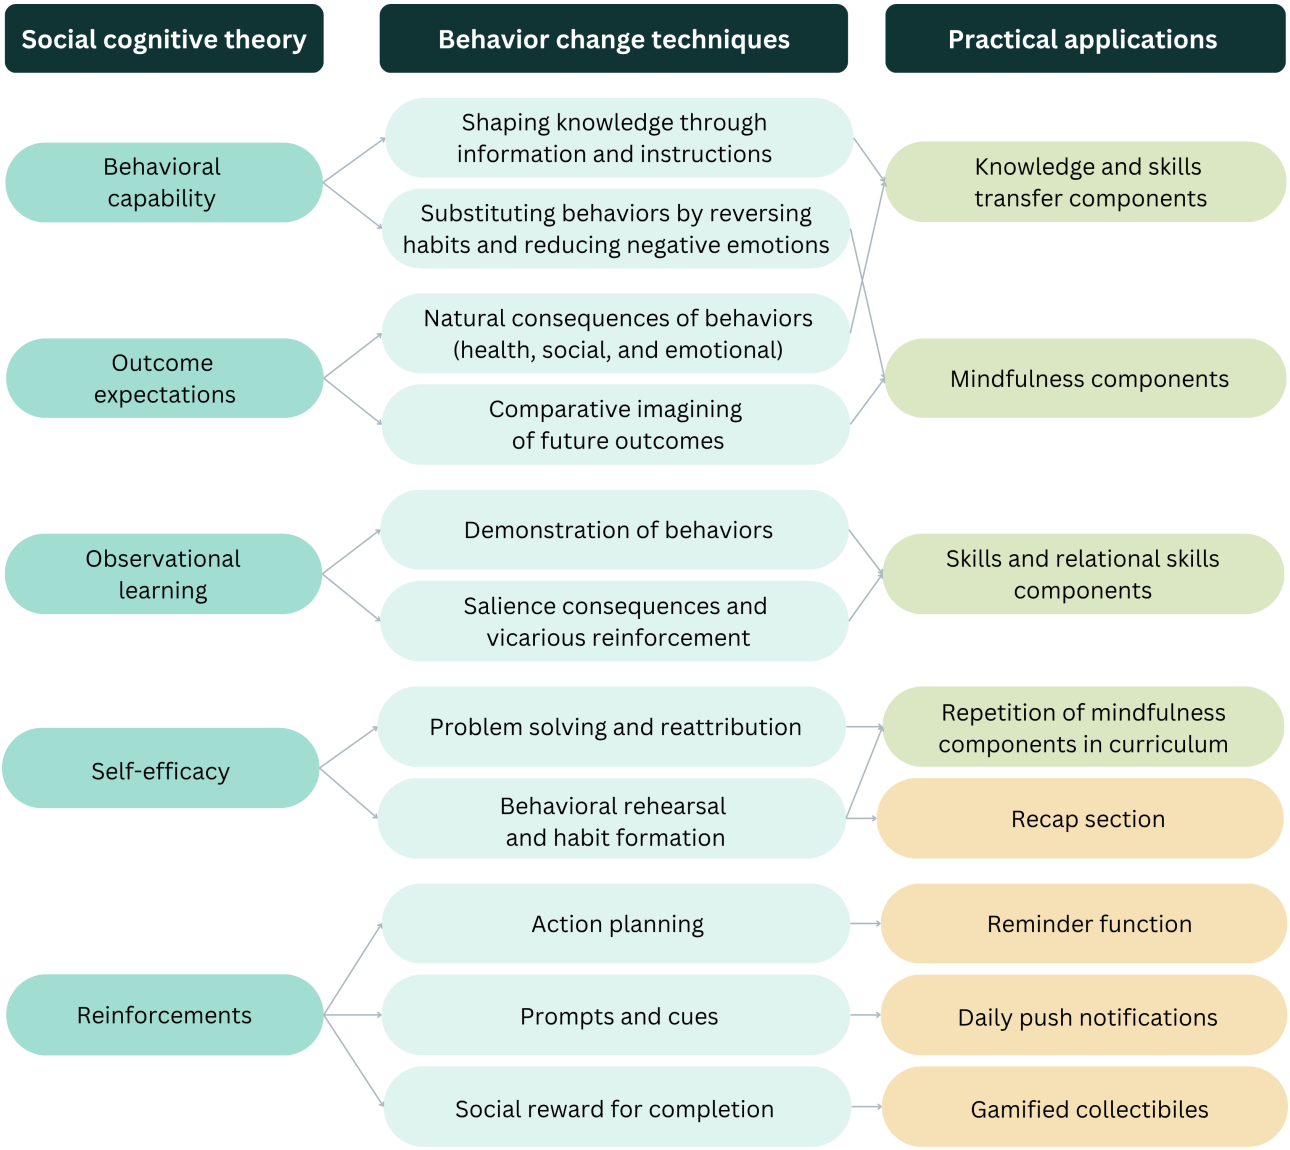
[b]Codes (eg, 1.1.1, 1.1.2, and so on) are with reference to Multimedia Appendix 3.

Step 3: Theory-Based Methods and Practical Applications

Mindfulness

As mindfulness is underpinned by key mechanisms of decentering and self-compassion, mindfulness practices for training attention control, decentering, and self-compassion, alongside practices that were further contextualized to parenting for ASD, were included in the app. This is important, as decentering can shift one's cognitive perspective to help reduce rumination [60,61], whereas self-compassion can increase positive affect and emotions for improving psychological well-being [62-64]. According to the warp and weft framework [65] that outlines the core essential elements and adaptable variable elements in MBIs, we preserved as many of the core essential elements in the curriculum and the content of the app. As direct inquiry is not possible in a self-taught format, the experiential, inquiry-based learning process was adapted by including debriefs that were intended to help parents reflect on their experiences and develop insight and understanding following the completion of guided mindfulness practices. Home practice was supported through convenient options for revisiting mindfulness practices through the intervention.

ELM



As ELM emphasizes how information processing may be done through the central or peripheral route depending on one's motivation and can lead to varying degrees of attitude changes, we developed intervention content on mindfulness and parenting for ASD that varied in depth and complexity (and therefore required different levels of cognitive efforts) to accommodate parents with different levels of motivation and cognitive abilities. For mindfulness content, gratitude practices, self-compassion practices, and attentional control training require less cognitive effort, whereas decentering practices, cognitive exercises, and relational skills require more cognitive effort. For psychoeducation content on parenting for ASD, knowledge transfer components require less cognitive effort, whereas skills transfer components, especially those explaining fundamental principles in psychological and behavioral science, require more cognitive effort.

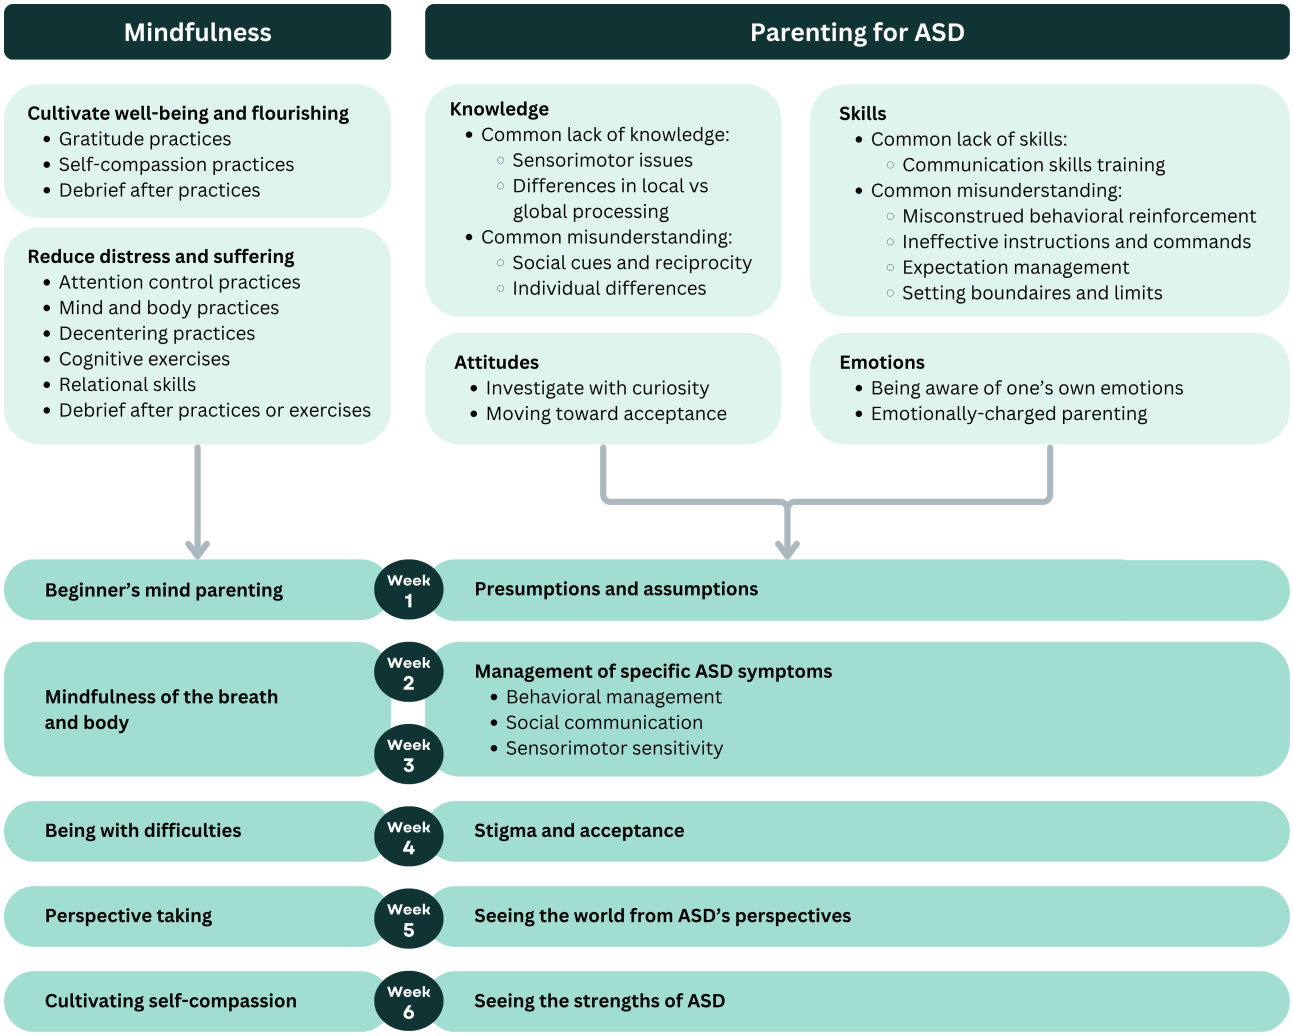
XSL•FO
RenderX

SCT

Figure 3 illustrates how BCTs were selected and applied to different SCT constructs (with details of how they map to specific change objectives provided in Multimedia Appendix 3). Intervention content for mindfulness and parenting for ASD was designed to target behavioral capability, outcome expectations, and observational learning. App features were designed to facilitate self-efficacy and reinforcements. For instance, we dedicated a section of the app to hold the entire collection of learning components to allow convenient revisiting and repeated practice. We also included a reminder function to help users set aside a specific time for completing the intervention, at which daily push notifications were sent to prompt users to log in and complete a session.

Figure 3. Social cognitive theory constructs mapped onto behavior change techniques for practical application.

Step 4: Program Development

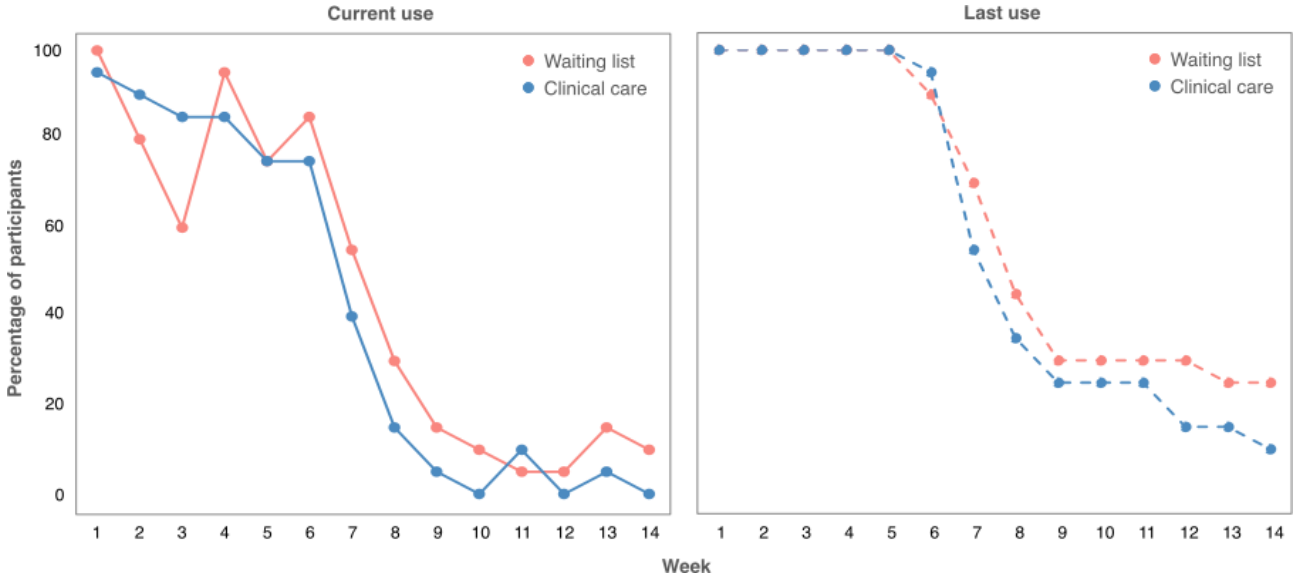


As “investigating with curiosity” was a recurring theme across interviews with health care professionals in step 1, the app was named TRIP and was designed as a journey for parents to learn more about themselves and their children through the cultivation of mindfulness and curiosity. The TRIP app is a 6-week structured intervention, with each week featuring a specific theme on mindfulness and parenting for ASD. Each week consists of 6 sessions, each session lasting 15 - 20 minutes; core and optional sessions are delivered on alternate days, with core sessions covering new content in greater detail, whereas optional sessions reinforce key messages of the week through self-directed learning. Within each session, learning components were delivered in different formats, including narrated animations (total duration=31 min, 7%), audio-guided meditation practices (total duration=307 min, 69%), and short articles (total duration=107 min, 24%). Each learning component focuses on either mindfulness practices, exercises, debriefing, and relational skills, or knowledge, skills, emotions, or attitudes in parenting for ASD, corresponding to the selected determinants of ASD caregiver challenges as identified in step 2. The app is currently available on App Store and Google Play in Chinese, with texts written in traditional Chinese characters and audio spoken in Cantonese, a popular Chinese dialect widely spoken in Hong Kong. Figure 4 illustrates the main screens of the TRIP app, and Figure 5 illustrates an outline of the themes and the intervention.

XSL•FO
RenderX

Figure 4. Main screens of the TRIP app translated into English.

Figure 5. Outline of the themes and components of the TRIP app. ASD: autism spectrum disorder.



In the pilot RCT, 117 participants were screened for eligibility. A total of 77 parents were excluded, as they did not meet the eligibility criteria (n=5), declined to participate (n=24), or did not respond to the screener survey (n=48). In total, 40 parents (90% female; 20 parents of children on the waiting list and 20 parents of children already receiving clinical care) were enrolled and randomized, with 20 allocated to the intervention group, and 20 allocated to the control group (2 parents dropped out

XSL•FO
RenderX

during follow-up, both were parents of children already receiving clinical care, and one allocated to the intervention group and the other to the control group). Most participants were female (n=36, 90%), while their children with ASD were mostly male (n=30, 75%) with a mean age of 5.18 (SD 2.46) years. There were no significant differences in participants' characteristics between the intervention and control groups (*P* values>.05). Multimedia Appendix 4 shows the CONSORT-EHEALTH flow diagram of the study, participants' characteristics at baseline, and detailed results for feasibility, acceptability, and preliminary efficacy outcomes.

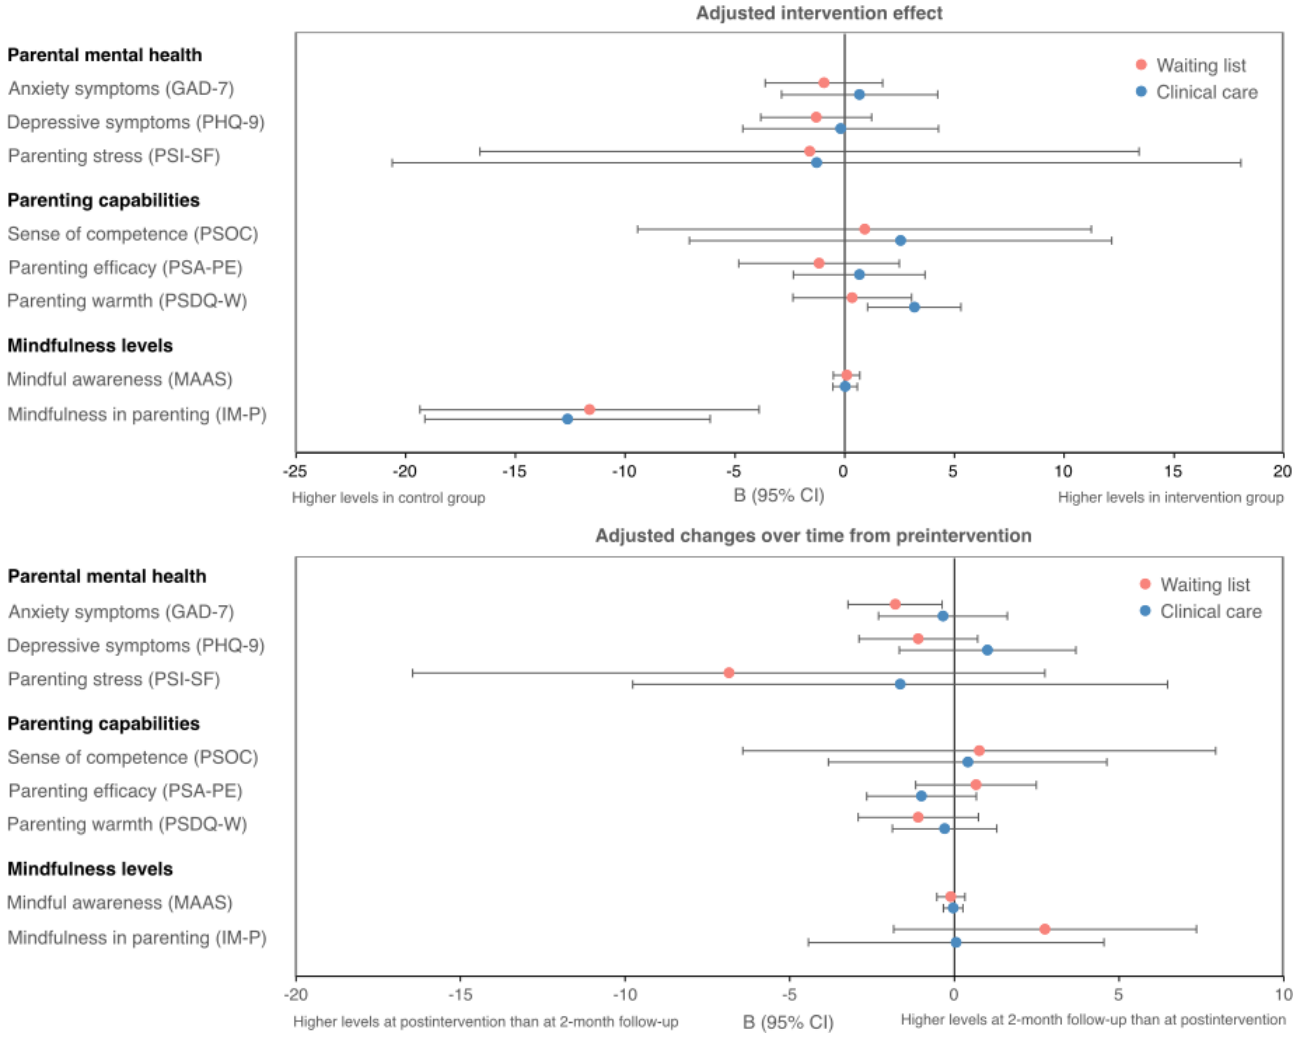


Figure 6. Week-by-week representation of participants' usage pattern during the active intervention period (weeks 1 - 6) and 2-month follow-up period (weeks 7 - 14).

For primary outcomes of feasibility and acceptability, the 6-week app-based structured intervention was both feasible and acceptable for supporting parents of children with ASD. Overall, the usage pattern is similar for parents receiving different levels of support during the active intervention period, whereas parents of children on the waiting list had a greater level of continued usage in the 2-month follow-up period than parents of children already receiving clinical care (Figure 6). All participants used the app during weeks 1 - 4, 92.5% (37/40) were still using the app at week 6, and 17.5% (7/40) continued using the app after the active intervention period. On average, participants completed 78.7% (65.3/83 unique components, SD 11.51) of the curriculum and 93.9% (16.9/18, SD 2.48) of the core sessions in the active intervention period, although the completion rate for optional sessions was rather low at 13.3% (2.4/18, SD 2.60). The overall usability of the system received a mean SUS score of 79.1 (SD 9.76) out of 100, reflecting "good" usability on the scale. The overall app quality based on the mean uMARS score was 4.09 (SD 0.41) out of 5. The app is highly rated for information (mean 4.52, SD 0.43), functionality (mean 4.43, SD 0.42), and aesthetics (mean 4.12, SD 0.55), whereas the rating for engagement is slightly lower (mean 3.29, SD 0.56).

XSL•FO
RenderX

Figure 7. Intervention effect and outcome changes over time from preintervention to postintervention and 2-month follow-up for efficacy outcomes, stratified by the levels of support received (waiting list vs clinical care). GAD-7: 7-item General Anxiety Disorder scale; PHQ-9: 9-item Patient Health Questionnaire; PSI-SF: 36-item Parenting Stress Index-Short Form; PSOC: 17-item Parenting Sense of Competence scale; PSA-PE: 6-item parenting efficacy subscale of the Parenting Self-Agency measure; PSDQ-W: 7-item warmth subscale of the Parenting Styles and Dimensions Questionnaire; MAAS: 15-item Mindful Attention Awareness Scale; IM-P: 31-item Interpersonal Mindfulness in Parenting questionnaire.

For the secondary outcome of preliminary efficacy, the intervention effect and outcome changes from preintervention to postintervention and 2-month follow-up are illustrated in Figure 7 (refer to Multimedia Appendix 4 for full results). There was no evidence of intervention effects on parents' mental health (GAD-7, PHQ-9, and PSI-SF), parenting capabilities (PSOC, PSA-PE, and PSDQ-W), and mindfulness levels (MAAS and IM-P) at 6-week postbaseline for parents receiving different levels of support, except for increased parenting warmth (PSDQ-W) among parents of children already receiving clinical care (B=3.17, 95% CI 1.04-5.30). Moreover, improvements in parenting warmth (PSDQ-W) were more favorable among parents of children who have already been receiving clinical care, whereas reductions in parental anxiety (GAD-7) and depression (PHQ-9) were more favorable among parents of children on the waiting list who were yet to receive diagnostic assessment and clinical management. Unexpectedly, there was a greater increase in the levels of mindfulness in parenting (IM-P) in the control group (parents of children on the waiting list: B=−11.62, 95% CI −19.34 to −3.90; parents of children already receiving clinical care: B=−12.63, 95% CI −19.13 to −6.13), although the CI was wide and, therefore, suggests uncertainties in the precision of these estimates. Comparing the outcome changes from preintervention to postintervention and 2-month follow-up, there were no notable continual improvements in most outcomes, except for a further decrease in parental anxiety (GAD-7) among parents of children on the waiting list (B=−1.80, 95% CI −3.23 to −0.37). Nonetheless, trends in outcome changes over time showed favorable reductions in parental depressive symptoms (PHQ-9) and improvements in parenting efficacy (PSA-PE) at 2-month follow-up for parents of children on the waiting list when compared with postintervention, whereas there were few changes in these outcomes from preintervention to 2-month follow-up for parents of children already receiving clinical care.

Discussion

Principal Findings

In this study, we used a systematic, evidence-informed approach according to IM to develop an accessible and scalable digital intervention to support parents and caregivers of children with ASD. To our knowledge, this is the first project of its kind in the field of autism, creating a family-centered intervention to

XSL•FO
RenderX

be implemented in primary care that complements existing clinical services and helps bridge service gaps in addressing unmet needs in the overloaded public specialist service system. This project is particularly intended to support families of children who are still on the waiting list to be seen by a psychiatrist for diagnostic assessments and clinical management. The digital format of the intervention also has great potential in reaching and providing an alternative avenue of care for those who are reluctant to seek conventional treatment due to concerns over privacy or mental health stigma. As the potential impact of improved parental mental well-being extends beyond parents themselves, this project can contribute to the effective management of elevated levels of parental stress in families of children with ASD and is potentially beneficial to both family functioning and child development in the long-term.

Through the IM process, the TRIP app was developed based on evidence-based research, incorporating existing findings from the literature and novel results from the explorative qualitative study with health care professionals conducted for needs assessment. Compared with MBIs developed for face-to-face or online synchronous delivery, the format of a digital platform posed constraints on the app content that can be covered, which may be limited in terms of depth and intensity to minimize the risk of harm or adverse events beyond the common, expected discomfort associated with meditation. For example, when exploring the theme of rupture and repair, instead of the more emotionally intense imaginary exercises in the Mindful Parenting program that may be potentially triggering, we created case studies of lower emotional intensity for observational learning to bring out the same learning points. In a similar vein, while research has emphasized the importance of partner relationships in parenting, it was not practical to address sensitive or highly individualized issues within an app-based format. As such, we have avoided the topic of partner relationships in the app, due to concerns about potential misuse between parents, including the possibility of parents undermining one another, or exacerbating conflicts between parents or separated coparents. Finally, the absence of a group learning environment, which is typical of MBIs, may limit the emergence of themes that often arise through collaborative exploration, such as the recognition of shared experiences of distress as part of our common humanity. This is because the sense of mutual understanding that arises in group settings can be particularly helpful for processing difficult emotions and realizations. Therefore, it would be interesting to implement app-based interventions within a group context, such as through peer support groups or similar networks in community settings, which is planned for later steps.

Feasibility and Acceptability of the App

Results from the pilot study suggest that the TRIP app is a feasible and acceptable way of delivering self-guided mindfulness-based psychoeducation for parents of children with ASD. All participants were actively engaged in the first 5 weeks of the active intervention period, with a low attrition rate of 7.5% at the end of the 6-week intervention, compared with a weighted meta-analytic attrition rate of 24.7% from 78 RCTs of mindfulness apps [66]. During the follow-up period, more than half of the participants revisited some learning components, and just under a third remained active users, with higher engagement among parents of children on the waiting list than parents of children already receiving clinical care. This is somewhat comparable to the engagement in mindfulness-based meditation apps in individuals awaiting psychological services [67]. Likewise, the completion rates of core sessions were substantially higher than those of optional sessions, likely because participants viewed optional sessions as nonessential, akin to the follow-up period. These observed usage patterns may be due to intrinsic factors related to the intervention structure, as the fixed course of core sessions for participants to progress through may have encouraged engagement and compliance, whereas optional sessions positioned outside of the core course scheduled with similar frequencies may have induced fatigue. Similarly, the learning components being available for revisiting in the follow-up period may have created decision-paralysis, thereby contributing to attrition from regular use. However, it is also possible that participants did not have the time to complete optional sessions during the week or did not feel the need to revisit any of the learning components in the follow-up period; therefore, spacing out optional sessions in the intervention period or releasing new learning components regularly in the follow-up period may increase engagement. On the other hand, extrinsic factors such as the study context, including support from research staff during the intervention period, may have acted as both a reminder and a source of accountability, thereby accounting for the increased app usage in the intervention period, as well as the decline in app usage in the follow-up period. This is in line with findings from a rapid scoping review suggesting that improved engagement with digital MBIs may be associated with additional support and encouragement from therapists, researchers, significant others, or other participants [68]. As such, this has been incorporated in the implementation plan, with staff across different settings included as implementers.

Preliminary Efficacy of the App

While we found that the app is feasible and acceptable for parents, there is little evidence for the preliminary efficacy of the app beyond the significant increase in parenting warmth among parents of children already receiving clinical care. An obvious explanation is that the pilot RCT is underpowered for detecting any intervention effects as a result of its small sample size. That said, trends observed in the data suggest that the app may potentially have different effects depending on the level of support children were receiving, as the app may be effective in reducing anxiety and depression in parents of children on the waiting list and increasing parenting efficacy in parents of children already receiving clinical care (in addition to a significant increase in parenting warmth). Moreover, the intervention effects may be delayed in parents of children on the waiting list, which was evident for further decrease in parental anxiety from postintervention to 2-month follow-up and indicated by similar trends observed for reductions in parental depression and improvements in parenting efficacy. This might be due to parents of children on the waiting list receiving minimal clinical support and, therefore, taking more time to understand and apply the knowledge and skills learned in the app to their everyday parenting. However, this means

XSL•FO
RenderX

that any intervention effects beyond the active intervention period may not be detected, as comparisons with controls were only made during the active intervention period. Trends for outcome changes from postintervention to 2-month follow-up also suggest that the app may bring greater changes to parents of children already receiving clinical care during the intervention period, as reductions in parental depression and improvements in parenting efficacy reverted to preintervention levels at 2-month follow-up. It will be interesting to further investigate this through conducting subgroup analyses with an adequately powered sample in the ongoing large-scale RCT.

Moreover, it may also be possible that the TRIP app may have effects that were not assessed by the outcome measures used in this study. We included measures of parental mental health and parenting capabilities in terms of parenting competence and efficacy, which were selected based on results of the explorative qualitative study. While outcomes selection in this study was in line with established frameworks for integrating parents and family into research and practice [7], measures of parenting behaviors, family interactions, or family quality of life were not included in this study and could be incorporated in the future to provide a more comprehensive evaluation of intervention efficacy and effectiveness. Also, while validated measurement tools were developed for measuring knowledge about ASD in the general population [69] and knowledge of parenting strategies [70], no instruments have been adapted to measure knowledge or skills in caregiving for ASD beyond autism-specific parenting self-efficacy [71]. As such, we did not examine whether there were increases in knowledge or skills for caregiving for ASD, as it would have been difficult to operationalize these changes in a valid and reliable manner in the absence of appropriate psychometric tools.

With regard to the unexpected effects of the app attenuating the natural increase in the levels of mindfulness in parenting, a plausible explanation for this draws on the conscious-competence learning model for the process of experiential learning [72]. As this outcome was measured by self-report, it is possible that participants were in the unconscious-incompetence stage at preintervention, in which they may not be aware of how little they know, and thus have unknowingly inflated their estimations of their levels of mindfulness in parenting. Subsequently, through the TRIP app, they may have progressed to the conscious-incompetence stage as their understanding of mindful parenting improves, and they began to recognize that they might not be as mindful as they had previously thought, thereby explaining the stark decrease in levels of mindfulness in parenting in the intervention group from preintervention to postintervention. In other words, parents may have become more aware of their nonmindful parenting as a result of using the TRIP app. Subsequently, through increased practice and application of skills acquired from the app, parents may have progressed to the conscious-competence stage, which may explain the slight increase in levels of mindfulness in parenting from postintervention to 2-month follow-up. This highlights the need to consider how to best operationalize changes in skills that can be learned over time, especially in light of the individual differences in learning and awareness.

Strengths and Limitations

This study offers several strengths. The approach for app development is systematic, evidence-based, and the use of a clinician-led, co-design approach enables the resulting digital intervention to be family-centered and complement existing clinical services. Moreover, the randomized waitlist-controlled design for the pilot study has the merits of conferring high internal validity and maintaining the gold standard of evidence without withholding the intervention from participants in the control group, offering a more ethical way of intervention testing. Apart from taking into account several important confounding factors (eg, child age and clinical characteristics), careful consideration of the role of the source of recruitment (triage service vs psychiatrist-led clinic) allowed us to gain valuable insights into how families receiving different levels of support may interact with and use the app differently, potentially contributing to differential intervention effects. The inclusion of server-side documented data also allowed us to understand how the app was used, as assessed by objective measures.

While this project has many strengths, there are also various limitations that need to be acknowledged. First, the high nonresponse rates may introduce sampling bias and potentially limit the generalizability of our findings. Moreover, it was possible that parents of children who were on the waiting list may have attended their first appointment with a psychiatrist for diagnostic assessment and clinical management during the intervention period. While psychiatric care is typically a long-term process that may take more time than the 6-week intervention period to show observable effects, any emerging improvements could have confounded the outcomes measured in the pilot study. However, the sample size in the pilot study was too small to adequately explore whether results varied by changes in the level of support received during the study period (eg, transitioning from waiting list to clinical care) or whether results vary by ASD severity. Furthermore, due to time and resource constraints, it was not possible to adopt a mixed methods approach for the pilot study. It would have been interesting to obtain qualitative data from participants to explore the factors influencing their compliance, which may inform how the app can be better implemented in the future to promote continual use beyond the 6-week structured intervention. In a similar vein, it was not practical to extend the waiting period in the waitlist control group beyond the length of the structured intervention, which meant that intervention effects were only compared during the 6-week intervention period and did not allow for any delayed effects to be compared.

Direction for Future Research

To address the potential biases and confounders that may arise in the pilot study, the ongoing large-scale RCT should compare whether response rates differ across key subgroups within the sample, explore whether results varied by ASD severity and changes in the level of support received from clinical services, and adjust for these factors accordingly. To overcome the limitation of the lack of direct evidence on parents' lived experience and qualitative user feedback in the pilot study, factors associated with enhanced user experiences and long-term

XSL•FO
RenderX

usage will be explored at the end of the ongoing RCT through qualitative interviews with parents and observations of naturalistic usage patterns beyond the active intervention period. Quantitative server-side documented data on app usage in the 6 months following the active intervention period will be analyzed to explore factors associated with long-term usage. Individual qualitative interviews (each lasting 30 - 60 min) will be conducted with parents to explore their user experience of the app, their subjective parenting experience, and their relationship with their children during the intervention period. The interviews will also seek feedback on how the content and delivery can be improved, and identify factors that may promote or hinder compliance with the intervention program. Results from the qualitative interviews will be used to refine the TRIP app before it is translated into English to complete the program development (step 4).

For adoption and implementation (step 5), we plan to implement the app according to a stepwise approach, commencing with implementation in clinical settings for families who are underserved by the public tertiary psychiatric services, followed by wider dissemination in the community through nonprofit organizations and local community centers, in order to be inclusive of those who may identify as neurodiverse but are unbeknownst to clinical services. A detailed implementation plan was devised as guided by the Reach, Effectiveness, Adoption, Implementation, and Maintenance (RE-AIM) framework [73] (Multimedia Appendix 5).

For program evaluation (step 6), a hybrid type 2 effectiveness-implementation trial will be conducted to evaluate both effectiveness and implementation outcomes simultaneously [74]. Implementers at different sites will be recruited and randomized to either the early implementation group or the delayed implementation group. Those who are allocated to the early implementation group will receive training and support for the implementation of the app immediately after randomization, whereas those allocated to the delayed implementation group will receive the implementation intervention once they have recruited the target number of parents of children with ASD. Implementation outcomes assessing feasibility, acceptability, fidelity, and sustainability will be measured at the end of the implementation period for the early implementation group, or immediately after randomization for the delayed implementation group, as well as at 3-month and 6-month follow-up after the first measurement. Effectiveness outcomes for mental health and quality of life outcomes for parents of children with ASD will be assessed at preintervention, postintervention, and at 3-month follow-up.

Apart from the planned implementation and evaluation, future studies can focus on investigating the mechanisms of change brought by the app by including measures of intermediate outcomes, such as attention and self-compassion. Future research can also include objective psychophysiological measures of depression and mindfulness alongside self-report measures by incorporating EMA, which was found to be more sensitive than paper-and-pencil measures [75].

Conclusions

In this study, we created an evidence-based digital intervention for parents of children with autism with an interdisciplinary approach at the heart of psychiatry, public health, and behavioral and implementation science. We demonstrated how we can incorporate behavior change theories and techniques while leveraging the experiences of clinicians for the coproduction of a feasible and acceptable digital intervention that complements existing clinical services in addressing pressing clinical needs. The TRIP app has great potential to be an economical, first-tier intervention in the stepped-care model for the holistic management of autism, by bridging service gaps through supporting parents of children awaiting diagnostic assessment and clinical care, and by improving resource allocation within existing clinical services through freeing up capacity to focus on complex cases that require more specialized, individualized, and intensive input.

Acknowledgments

The authors would like to thank our professional acquaintances at the Alice Ho Miu Ling Nethersole Hospital (AHNH) in Hong Kong for their referral and participation in the qualitative study for needs assessment, as well as the invaluable insights they have provided throughout the app coproduction process. We would also like to acknowledge the app design team for software development, graphics design, animations production, and text editing for app development. The authors would also like to thank all the families who participated in the pilot study, and acknowledge Miss Phoebe Or for supporting participants' recruitment and data collection and Mr Felix Kok for supporting data cleaning for the app usage data in the pilot study.

Funding

The development of the app was supported by The D. H. Chen Foundation, and the pilot evaluation of the app was supported by the Health and Medical Research Fund (Ref: 10210356). For the purpose of Open Access, the authors have applied a Creative Commons Attribution (CC BY) licence to any Author Accepted Manuscript version arising.

Data Availability

The datasets generated or analyzed during this study are available from the corresponding author on reasonable request.

Authors' Contributions

All authors have made conceptual contributions to the project design and procedures. KKYM, SSMC, EWYW, OC, GPCF, and OWHW contributed to the iterative development of the digital intervention. KKYM, SSMC, OC, and OWHW conducted the qualitative study for needs assessment and quantitative study for pilot evaluation. KKYM conducted all analyses and drafted the initial manuscript. All authors commented on previous versions of the manuscript. All authors read and approved the final manuscript.

Abstract

Background: Geography and socioeconomic disadvantage impede access to appropriate services for rural and remote-dwelling children with complex developmental and mental health needs. Telehealth offers opportunities to increase access to essential health and well-being services for people with complex needs who live in rural and remote areas, whose experiences of mental ill-health are frequently compounded by social marginalization and economic disadvantage.

Objective: This study aimed to describe caregivers' and service providers' perspectives on the challenges and value of telehealth services for rural and remote children by drawing on experiences within a specialist service (Royal Far West; RFW) that provides mental and developmental health services to rural and remote-dwelling children and families in Australia.

Methods: Participants included a convenience sample of caregivers of children who use RFW services (n=11) and service providers from RFW (n=21). Deidentified interview transcript data were analyzed thematically using framework analysis.

Results: Caregivers were generally enthusiastic about telehealth but acknowledged potential technological limitations and challenges to effectively engaging some children. While acknowledging its value and importance, RFW service providers identified additional challenges with providing telehealth, such as limited capacity for some detailed clinical assessments and potential child and family risk and safety issues.

Conclusions: Telehealth remains a vital option within multidisciplinary services to improve access and outcomes for children in rural and remote communities who present with complex mental and developmental health needs. Despite challenges, rural and remote caregivers and RFW service providers identified telehealth as a beneficial, accessible, and effective component of multidisciplinary care for children with complex mental and developmental health needs. These caregiver and service provider perspectives will inform ongoing service development, research, and advocacy.

Introduction

Background

Geography and socioeconomic disadvantage often make it difficult for rural and remote-dwelling Australian children with complex developmental and mental health needs to access appropriate services [1]. Clinical, family, and community complexity likely also influences service engagement for these families, whose experiences of mental ill-health are frequently compounded by social marginalization and economic disadvantage [2]. Although the prevalence of child and youth mental health problems is increasing across Australia [3], fewer than one-third of children currently receive the mental health services they require nationally [4]. Furthermore, although children and young people living in rural and remote communities experience poorer mental health [5] and developmental outcomes [6] than those in urban locations, their use of mental health services is considerably lower than that in urban areas in Australia [7] and internationally [8,9].

Telehealth offers opportunities to increase access to essential health and well-being services for children with complex mental and developmental health needs who live in rural and remote

XSL•FO
RenderX

areas [10]. In this paper, "telehealth" refers to a combination of video consultations, telephone calls, and digital platforms used for client engagement, assessment, and therapy, which are sometimes supplemented with face-to-face consultations. A recent systematic review of telehealth screening, assessment, and diagnosis of autism spectrum disorder (ASD) found that telehealth facilitated the standardization, sensitivity, specificity, and efficiency of screening, assessment, and diagnosis of ASD [11]. Similarly, a systematic review of telehealth services to assess and treat neurodevelopmental disorders found that these services were clinically effective, cost-effective, and acceptable to caregivers [12]. Telehealth has been found to be convenient and cost-effective, as well as supportive for high-risk populations, given its ability to remove geolocation barriers [13]. Furthermore, telehealth as a psychological intervention for caregivers of children with neurodevelopmental disorders has been shown to improve mental health outcomes [14].

Telehealth is also acceptable to children and families seeking diverse and complex health and well-being care remotely [15]. For example, a recent systematic review of telehealth interventions for children with ASD found that telehealth programs are highly acceptable even when compared to face-to-face interventions and noted the vital role of telehealth for enhancing equitable access to interventions for rural and remote communities [16]. When facilitated through partnerships with Aboriginal community-controlled health services, telehealth services are also effective and acceptable to Aboriginal and Torres Strait Islander individuals and communities [17]. Furthermore, ease of use, improvements in outcomes and communication, and reductions in costs support patient satisfaction with telehealth [18].

However, most pediatric neurodevelopmental studies from Australia and abroad have reported telehealth benefits primarily in urban populations, providing limited data on rural and remote communities. Furthermore, they have not explored hybrid telehealth and face-to-face models. There is a need for studies focused on these populations and models of care to address knowledge gaps. Therefore, the aim of this study was to describe caregivers' and service providers' perspectives on the challenges and value of telehealth services by drawing on experiences within Royal Far West (RFW), a specialist service providing mental and developmental health services to rural and remote-dwelling children and families in Australia.

Study Context

RFW is a charitable, nongovernment, specialist child health service located in Sydney, New South Wales, Australia, that provides developmental, mental health, and disability support for children up to the age of 12 years in rural and remote settings using a mixed model of care that includes telehealth. Given its clientele, RFW was an early adopter of telehealth, using it for assessment and therapy in a range of clinical disciplines since 2015, well before the COVID-19 pandemic accelerated its use. RFW services have been adapted over time to integrate telehealth within their standard models of care, with telehealth becoming an integral modality to enhance and maintain engagement and reduce barriers to access.

Thus, telehealth is part of the standard assessment and therapy provided by RFW in all clinical services. Telehealth at RFW is provided by speech pathologists, occupational therapists, psychologists, social workers, nurses, pediatricians, and psychiatrists. It is used as both stand-alone care and to complement face-to-face care. For example, in the assessment-focused pediatric developmental service, telehealth is used before, after, and between face-to-face residential assessment visits in Sydney. Telehealth introduction consultations involve a pediatrician and allied health clinician connecting with the child and their caregivers, reviewing referral information, and assisting in planning for the upcoming visit. After the on-site or in-community (outreach) assessment with a multidisciplinary team, telehealth is used for diagnostic feedback from the multidisciplinary team and care planning with the caregiver. It is also used for ongoing care (eg, for medication management), interim progress reviews prior to further face-to-face assessments, and group parenting programs. Telehealth sessions are typically conducted with the child and caregiver at home, although for families with limited internet connectivity or other problems with access, sessions are conducted from the child's school or another service provider (eg, child protection or health service offices).

RFW's community-based disaster recovery service provides individual telehealth therapy sessions to children impacted by bushfires and floods. Telehealth is used for therapy (eg, eight 45-minute weekly sessions for psychological, occupational, or speech therapy) or for parent capacity building (eg, *Tuning in to Kids* parenting program). These programs supplement children's group programs or teacher capacity building programs that are delivered face-to-face during in-community (outreach) visits. Thus, at RFW, telehealth is integrated into all models of care and used for rapport building and service familiarization, diagnostic assessment, feedback and psychoeducation, therapy, care planning, progress review, and follow-up, as well as parenting programs, often to complement face-to-face care. Hence, telehealth can be an enabler of service engagement for rural and remote families along their care journey when used dynamically.

Methods

Study Design

The data presented in this paper were collected as part of a broader exploratory sequential mixed methods study. For the qualitative component of the study, a convenience sample of current RFW service providers and caregivers of children who had used RFW services within the 2 years prior to when the interviews were conducted were invited to participate in an interview. Semistructured interviews allow for detailed exploration of participants' experiences and perceptions, including the ability to ask follow-up questions. Interview questions were provided to participants in advance of the interview so they had time to prepare their thoughts. The interview questions focused broadly on challenges and enablers of service engagement throughout a family's service journey, with a substantial portion of the interview focusing specifically on experiences with telehealth. Questions were piloted with 2

XSL•FO
RenderX

individuals and refined prior to participant recruitment, resulting in minor changes to question wording.

Data Collection

Interviews were conducted by a non-Indigenous female individual with extensive qualitative and mixed methods research experience who was employed as a postdoctoral researcher. Although the interviewer had presented the study outline earlier to many of the RFW service providers who later chose to participate, she had no prior relationship with caregiver interview participants. To facilitate rapport and relationship building, all interviews began with an invitation to ask the interviewer any questions about the study or the interviewer herself. All interviews took place online using Zoom teleconferencing software (Zoom Video Communications) and were audio recorded and transcribed using Zoom's verbatim transcription service.

Analysis

Once data saturation was reached, the interview data were analyzed thematically [19] using framework analysis [20], which includes the following 7 steps: (1) transcribing, (2) familiarizing oneself with the interview, (3) coding, (4) developing an analytical framework, (5) applying the analytical framework, (6) charting the data into a framework matrix, and (7) interpreting the data. Data were independently coded by 2 members of the research team, who identified emerging themes deductively using the Microsoft Word and Microsoft Excel software. Framework analysis allows for findings to be traced directly to primary data.

Ethical Considerations

This study was approved by the University of Sydney Human Research Ethics Committee (2024/HE000682) and all participants provided written informed consent before participating in an interview. Interview participants were provided with an AUD $30 (US $24.50) grocery voucher in gratitude for their time.

Results

Participants

Semistructured interviews were conducted with 11 caregivers, all of whom were female and 81.8% (9/11) of whom were non-Indigenous, and 21 RFW service providers, including psychologists (n=3, 14.3%), social workers (n=4, 19%), occupational therapists (n=3, 14.3%), speech pathologists (n=6, 28.6%), pediatricians (n=2, 9.5%), and operations staff (eg, bookings or caregiver support services; n=3, 14.3%). Findings from the caregiver interviews are presented first, followed by service provider interview findings.

Caregiver Findings

Three themes were identified within the caregiver interview data: (1) challenges with telehealth, (2) value of telehealth, and (3) settings for telehealth (Table 1). Some caregivers found telehealth to be a challenge, noting their children's resistance to engaging with telehealth; distractions in the household setting; the inconvenience of the timing of telehealth appointments; and technological issues such as satellite internet, which is vulnerable to weather changes. Other caregivers found telehealth very helpful, noting as strengths their own and their children's fluency with technology and the opportunity to access services that would otherwise be inaccessible. Finally, some caregivers recommended ensuring that the physical setting is conducive to telehealth.

XSL•FO
RenderX

Table . Caregiver interview findings regarding the challenges and value of telehealth.

Theme	Illustrative quotes
Challenges of telehealth	• "We struggle with telehealth. [Child] just can't. He struggles with social interaction as it is, let alone being face-to-face with someone on a computer. It just didn't work for us. I don't think there was anything that [Royal Far West] could do to make it better. They did try their best. But yeah." [PDPF03] • "And with the telehealth visits, at times I'd have the other kids. So, they'd be in the background watching TV. And then [oldest child] gets distracted. [And] the first was a week of telehealth visits. [...] We've only got satellite Internet. So, the pings have got to physically go up 30,000 Ks and back down. So, sometimes I'm still talking, and then someone else starts. Like, it doesn't quite exactly work." [PDPF02]
Value of telehealth	• "I don't see many challenges with telehealth because I've been using telehealth for a few years. And as someone who lives regionally, where services are so limited face-to-face, and I'm time poor. I work full time; I'm a single parent to two kids. So, I guess the general challenges would be, yes, you're not seeing the person face-to-face, and that sort of stuff. But I don't really see a challenge with telehealth. Had that [parenting] course been done any other way, I wouldn't have been able to do it. Wouldn't have mattered weekend, daytime, afternoon, I simply would not have been able to do it. So, I think it's fantastic that we have a telehealth." [CRPF01] • "I'm very confident and capable with technology. So, I wasn't apprehensive. I found no challenges with that. [...] [Child] has no challenges with digital tech, either." [CRPF03] • "I don't remember there being any massive challenge [with telehealth]. I could see how someone a little bit more remote than me, or more rural than me could have internet issues, Wi-fi. Sometimes, if it's really windy here, we'll have trouble with our Wi-fi. But I think I was really lucky in a sense of I never really had any trouble like that." [CRPF02]
Settings for telehealth	• "Making sure the space is right. If you're a family and you're in a small house, like a lot of families have multiple people living in a house, it's too distracting for a child. You need to make sure the space for the telehealth session to actually go ahead [is] quiet. Are they going to be able to focus?" [PDPF04]

Service Provider Findings

Four main themes emerged from the service provider interview data: (1) the value of telehealth for rural and remote families, (2) implications of technology, (3) clinical challenges of telehealth, and (4) risk and safety (Table 2). Many service providers noted the value of telehealth, particularly in terms of its low cost to both families and RFW, facilitating access to care in the absence of other alternatives in local communities, and its demonstrable effectiveness for some disciplines. Others noted that some children respond really well over telehealth, whereas other children prefer face-to-face appointments. However, service provider interview respondents also noted several challenges with telehealth, including technological challenges for rural families, such as limited internet connectivity and difficulties accessing laptops or tablets for appointments.

XSL•FO
RenderX

Table . Service provider interview findings regarding the value and challenges of telehealth for rural and remote families.

Theme	Illustrative quotes
Value of telehealth for rural and remote families	• "I think telehealth is amazing, because so many of those kids in rural, regional New South Wales, the waitlist is so long, or it's so expensive, or they just don't have any local services, or the local service is a two-hour drive away. So, telehealth is great in that we can offer them a service where they couldn't get it otherwise." [PDPS09] • "The evidence, particularly for speech pathology, a lot of the evidence says [telehealth] is just as effective as in-person therapy. [...] So, I think it's beneficial in terms of ease of access, cost, and we know that it's just as effective. We can meet goals." [PDPS13] • "From an [occupational therapy] perspective, I was...kind of surprised at how well you can go on telehealth in terms of running different OT activities, chatting to parents, building relationships over telehealth has been amazing. And that's the same for assessment as well." [PDPS08]
Implications of technology	• "The availability of technology. Some families might not have a laptop where they can sit down and have the zoom sessions and things like that. So that can be quite tricky, or they might not have good Internet at home, so that their availability of accessing telehealth can be tricky." [PDPS08] • "I think working on telehealth actually made me a much better [occupational therapist] in terms of me not being so reliant on equipment or games of those kind of things. Just thinking about, what can we do just with our bodies? Just being able to run an OT session with almost nothing. Very basic." [CRPS06]
Clinical challenges of telehealth	• "I find telecare incredibly challenging, for the social work role specifically.... I actually haven't found telecare assessments that clinically valuable because we're expected to do a [relatively] quick assessment. ...I think to build the rapport, to deep dive into your mental health, your relationship with your partner that you're parenting with, or the reason why you've separated your co-parenting, what choices or strategies do you use in your parenting? All these pretty significant personal topics. To get there via telecare can feel really challenging. ...I just don't ever think I get the same depth." [PDPS03] • "I do think telecare is a bit of a challenge. It certainly opens up doors in the sense of that means that we can check in with families, but it absolutely 100% does not replace a face-to-face assessment." [PDPS15]
Risk and safety	• "Challenges with telehealth and never knowing the full picture can put clinicians and the child at risk of child protection concerns—if child protection concerns are apparent [but] not able to be addressed, identified, and appropriately addressed." [CRPS01]

Another challenge noted by service providers was the limited depth of clinical assessments possible for some disciplines such as social work. Some service providers also found standardized assessments difficult to complete via telehealth, noting that, at times, it is difficult to engage children on-screen for adequate periods. Service providers also commented on risk and safety concerns for children and their families when using telehealth, particularly in relation to gauging off-screen activities. As one service provider expressed, "I just don't trust what I can't see on screen" (PDPS03).

Summary

In summary, although caregivers identified challenges, they also asserted the value of telehealth for multidisciplinary mental and developmental health assessments and treatment. Service providers reflected on both strengths and challenges associated with telehealth for multidisciplinary developmental and mental health assessment and treatment.

Discussion

Principal Findings

Caregivers and service providers articulated common themes when discussing the benefits and challenges of telehealth service delivery within a multidisciplinary pediatric developmental and mental health service for rural and remote children. Caregivers experienced challenges with telehealth yet valued it for its ability to facilitate access to otherwise inaccessible services. They also described the importance of ensuring that settings were conducive to telehealth assessment and treatment. Meanwhile, service providers reflected on the value of telehealth, particularly in terms of lower costs, easier access, and its demonstrable effectiveness for some clinical disciplines. Nevertheless, they

XSL•FO
RenderX

also identified challenges with telehealth, including risk and safety; implications of technology; and depth of clinical assessments, particularly in relation to psychosocial evaluation. Importantly, while both caregivers and service providers expressed some concerns about telehealth, both groups shared an appreciation for how telehealth allows rural and remote children to access multidisciplinary developmental health services, especially given the dearth of appropriate services in rural and remote locations in Australia.

Cross-referencing caregiver and service provider perspectives on the challenges and value of telehealth for pediatric developmental and mental health reveals that multidisciplinary and multimodal telehealth can be an enabler of service engagement for rural and remote families along their care journey, particularly when used dynamically. For example, at RFW, telehealth is used for rapport building and service familiarization, diagnostic assessment, feedback, psychoeducation, therapy, care planning, progress review, and follow-up, as well as parenting programs. Thus, our findings suggest that telehealth can be effective for this range of activities when used to complement face-to-face consultations. Telehealth diagnostic assessment of complex developmental disorders elicited high levels of acceptance from caregivers and service providers despite limitations such as technical issues.

Our findings are consistent with those of international and Australian literature regarding telehealth in urban settings. For example, in an Australian metropolitan pediatric context, the use of telehealth in the diagnostic assessment of complex developmental disorders received high levels of acceptance from caregivers and service providers despite limitations similar to those observed in our study, such as technical issues, because it reduced costs, increased flexibility, and accommodated family needs [21]. Similarly, the international literature indicates that implementing telehealth in urban settings holds promise for greater accessibility of child mental health services [22], including pediatric psychiatry [23]. Our findings are also consistent with findings that telehealth supported increased rates of rural and remote patient satisfaction with allied health services such as occupational therapy and speech pathology [24].

Implications

Our study suggests several implications and recommendations for policy and practice in the field of telehealth for child mental and developmental health assessment and treatment. First, rural and remote communities without access to face-to-face services should have access to telehealth services that incorporate family, educational, and societal factors impacting the child. This would empower children and families with psychosocial or neurodivergent complexity to seek care and optimize access to government rebates for care needs that depend on multidisciplinary clinical assessment. Second, to be effective, digital literacy and internet connectivity must be assured. Finally, service provision staff must be supported to deliver telehealth services in integrated and dynamic ways.

Strengths and Limitations

One strength of our study is that it triangulates primary data from both caregiver and service provider interviews, facilitating comparisons of their experiences and perspectives. In addition, member checking of primary data before analysis, reflexivity throughout the analysis period, and an audit trail supported by the systematic stages of framework analysis strengthened the rigor and quality of data interpretation. However, this study had several limitations. For example, one potential limitation is self-selection bias because participants who voluntarily chose to take part represent only part of the client cohort. Similarly, caregiver interviewees were all biological mothers, omitting the perspectives of other caregivers (eg, fathers or grandparents). Another limitation relates to constraints on transferability given the relatively small sample sizes, as well as the fact that service clients (ie, children) were not engaged directly in the research. Despite these limitations, our qualitative findings provide important insights into the role of telehealth for rural and remote access to developmental and mental health services.

Directions for Future Research

Future studies should explore rural and remote children's experiences of telehealth and how it can inclusively engage and support neurodivergent or culturally diverse groups. Caregiver perspectives on unique aspects of telehealth clinician interactions, including supportive evaluation of child and family risk issues, could also be explored. Given the centrality of telehealth to rural and remote care, ongoing investigation of innovative telehealth neurodevelopmental assessment and therapeutic tools should be pursued, as well as comparison of care satisfaction, impact, and outcomes of telehealth vs hybrid telehealth and face-to-face care.

Conclusions

Although there are challenges with telehealth, it remains a vital option within multidisciplinary services to improve access and outcomes for children in rural and remote communities who present with complex mental and developmental health needs. Telehealth can be used to deliver a range of clinical services and offers opportunities to develop new clinical approaches. Future work should explore approaches that allow for the adaptation of in-person assessments to telehealth and improve service provider skills in engaging children using telehealth. As technology improves, so should the accessibility of telehealth-delivered care.

Abstract

Background: Postpartum psychological distress, ranging from transient mood and anxiety disturbances to full-syndrome postpartum depression, is prevalent. Many postpartum individuals lack access to evidence-based interventions due to stigma and insufficient provider availability. The treatment gap is particularly pronounced among historically marginalized groups, including Black, Hispanic/Latina, and low-income mothers. Digital health interventions offer support to address this.

Objective: We aimed to evaluate the feasibility, acceptability, and preliminary efficacy of Woebot for Postpartum Mood and Anxiety (W-PPMA), a smartphone-based relational agent delivering cognitive behavioral therapy–informed psychoeducation to postpartum individuals.

Methods: This randomized controlled trial recruited participants from the PowerMom study, a digital platform for maternal health research. Eligible individuals (≥16 y, <3 mo post partum) were randomized to W-PPMA or a waitlist control condition. W-PPMA, an investigational digital mental health intervention, features a relational agent delivering cognitive behavioral therapy–based psychoeducation via text-based conversations. Primary outcomes included feasibility (Usage Rating Profile–Intervention Revised, Feasibility Subscale), acceptability (Usage Rating Profile–Intervention Revised, Acceptability Subscale), and satisfaction (Client Satisfaction Questionnaire–8) assessed at the 8-week end of intervention (EOI). The secondary outcome was change in depressive symptoms (Patient Health Questionnaire–8) among those with elevated baseline symptoms. Exploratory outcomes included anxiety (Generalized Anxiety Disorder–7 items), stress (Perceived Stress Scale), perinatal depression (Edinburgh Postnatal Depression Scale), Mother-to-Infant Bonding Scale, and therapeutic alliance (Working Alliance Inventory–Short Revised). This study followed CONSORT (Consolidated Standards of Reporting Trials) guidelines and received Institutional Review Board approval.

Results: Of 267 participants (W-PPMA=144, waitlist=123), mean age was 32.2 (SD 5.1) years; 12.7% (n=34) identified as Hispanic/Latina, 8.6% (n=23) as Black, and 68.5% (n=183) as White. W-PPMA users engaged with the app a median of 9 (IQR 5 - 24) days across 4 active weeks (IQR 2 - 7). At EOI, W-PPMA participants reported high feasibility (Usage Rating Profile–Intervention Revised, Feasibility Subscale median 31, IQR 28 - 34), acceptability (Usage Rating Profile–Intervention Revised, Acceptability Subscale median 30, IQR 28 - 34), and satisfaction (Client Satisfaction Questionnaire–8 median 26, IQR 24 - 29). Among those with baseline depressive symptoms (n=97), Patient Health Questionnaire–8 scores improved modestly in the W-PPMA group compared to waitlist (mean change −0.7, SD 3.4, vs 0.0, SD 4.8; Cohen *d*=−0.16). Exploratory analyses showed a statistically significant between-group difference in Perceived Stress Scale change at EOI (mean difference −1.59, 95% CI −2.4 to −0.73) and a nonsignificant between-group difference in Edinburgh Postnatal Depression Scale change (mean difference −0.51, 95% CI −1.36 to 0.34). Therapeutic alliance (Working Alliance Inventory–Short Revised) was strongest at baseline among Black participants and those from socioeconomically disadvantaged neighborhoods (Area Deprivation Index ≥75). Participants with a high school or General Educational Development reported the highest satisfaction scores, underscoring accessibility across educational backgrounds.

Conclusions: W-PPMA met primary study aims. Preliminary evidence and these findings support W-PPMA, warranting further evaluation in larger trials.

Introduction

Prevalence and Burden of Postpartum Blues and Postpartum Depression

The postpartum period is a time of significant lifestyle, relational, and physical health changes, often accompanied by psychological distress and profound impacts on maternal mood. In this study, we use the term postpartum "psychological distress" to refer to a spectrum ranging from transient mood and anxiety disturbances to full-syndrome postpartum depression (PPD), consistent with the most common manifestations in the early postpartum period. Broader definitions of perinatal mood and anxiety disorders also include posttraumatic stress symptoms [1], which were not assessed in this study. Understandably, many mothers experience various mood and anxiety symptoms and labile emotions after birth, such as mood swings, crying spells, anxiety, irritability, sadness, and feelings of being overwhelmed [2-4]. These symptoms, often referred to as "baby blues," typically begin within the first 2 - 3 days and resolve without intervention within 2 weeks for most individuals [5]. However, recognition and management of persistent postpartum mood and anxiety symptoms is critical, as they are not only distressing to mothers and their families but also represent a risk factor for the development of full-syndrome PPD and anxiety disorders [4,6].

As many as 75% of women report some degree of mood and/or anxiety symptoms after birth [5]. Full-syndrome PPD affects approximately 13% - 20% of postpartum individuals in the United States, with prevalence varying significantly by state and demographic group [4,7]. PPD is associated with adverse outcomes, including increased maternal morbidity and mortality [8], impaired maternal-child interactions [9], diminished parenting behaviors, and cognitive, emotional, and behavioral challenges in child development [10].

Current Treatment

Treatment of peripartum mood and anxiety symptoms typically involves psychotherapy and/or antidepressant therapy. Cognitive behavioral therapy (CBT) and interpersonal psychotherapy (IPT) are recommended as first-line treatments for mild to moderate postpartum mood and anxiety concerns, while antidepressant pharmacotherapy is reserved for more severe cases of PPD [11]. CBT aims to address the reciprocal interactions between thoughts, feelings, and behaviors by challenging negative thought patterns and promoting adaptive behaviors [12]. IPT focuses on alleviating symptoms by improving interpersonal functioning, communication, and role clarification in response to relational challenges [13]. Techniques derived from these psychotherapies are beneficial not only for mothers diagnosed with PPD but may also provide effective mental health and emotional support for nonclinical populations.

Barriers to Mental Health Care Support

Despite the existence of evidence-based treatments for peripartum mood and anxiety, many postpartum individuals do not seek or engage in care, even when recommended by health care providers [14,15]. Stigma surrounding mental health is a significant barrier to help-seeking and treatment usage [16]. Additional barriers include a shortage of qualified therapists, inflexible scheduling, long wait times, childcare challenges, transportation difficulties, and affordability concerns [14]. For pharmacotherapy, concerns about antidepressant transmission through breast milk further limit its use [17]. These barriers are especially pronounced among Black, Hispanic/Latina, and low-income mothers, who face higher risks of PPD and significant systemic inequities in accessing care [18].

Low representation of historically marginalized groups in health research exacerbates disparities, reducing the generalizability of findings and hindering the development of effective interventions [19,20]. Ensuring diverse inclusion in research is critical to addressing health inequities and improving outcomes.

Digital Interventions

Digital mental health interventions (DMHIs) offer promise for postpartum mental health support. In this paper, we focus on fully automated, app-based DMHIs such as Woebot, which deliver psychoeducation and coping strategies without requiring a live clinician. We acknowledge that telemedicine-delivered psychotherapy, such as CBT provided by a therapist via video or phone, has also grown substantially, with recent evidence [21] showing it to be noninferior to in-person care with high satisfaction rates across diverse populations. While this is an important parallel development, our study centers on the potential of automated DMHIs to scale support where clinician-delivered therapy is not available [22]. Such DMHIs provide private, stigma-free support, which is particularly relevant for postpartum mothers navigating the unique demands of early parenthood [23]. Moreover, their scalability enables broader population reach, including individuals who might otherwise receive no care.

To address these challenges, this study leveraged the PowerMom mobile research platform [24], chosen for its ability to facilitate decentralized, bilingual (English and Spanish), and scalable data collection for maternal health. PowerMom's capacity to enable remote participation, inclusivity, and generalizability makes it valuable for engaging underrepresented populations in research.

The intervention evaluated in this study is Woebot for Postpartum Mood and Anxiety (W-PPMA), an investigational

XSL•FO
RenderX

DMHI that offers a guided self-help program that delivers CBT psychoeducation and self-management techniques through brief text-based conversations with a relational agent named Woebot. Woebot is intended to present to users a friendly, helpful, self-help ally that is explicitly not a human or a therapist. Neither W-PPMA nor Woebot have been evaluated, cleared, or approved by the Food and Drug Administration and are not available for general use. W-PPMA integrates evidence-supported techniques from CBT and IPT, specifically tailored to the postpartum experience. Earlier prototypes of Woebot have demonstrated feasibility, acceptability, and preliminary efficacy in improving anxiety and depression symptoms among young adults [25], postpartum women [26,27], and adults addressing substance use [28,29]. Building on these foundations, W-PPMA aims to offer a specialized approach to address the unique mental health needs of postpartum mothers. While prior work in postpartum populations has been limited to smaller pilot trials, this study extends this evidence by conducting the largest randomized evaluation of Woebot in a postpartum cohort to date, with a deliberate emphasis on recruiting underrepresented racial, ethnic, and socioeconomic groups.

The primary aim of this study is to evaluate the feasibility and acceptability of W-PPMA, using app usage and validated measures, among a diverse group of postpartum women. The secondary aim is to assess the preliminary efficacy of W-PPMA relative to a waitlist control condition in managing symptoms of depression at the 8-week end of intervention (EOI) among participants with elevated baseline depressive symptoms. Exploratory aims include (1) examining potential between-group differences in perceived mother-infant bonding, mood and anxiety symptoms, and perceived stress; (2) evaluating therapeutic bond with Woebot at 1 and 8 weeks; and (3) assessing feasibility, acceptability, perceptions of stigma as a barrier to mental health care, and mood outcomes across key sociodemographic variables (eg, race and ethnicity, age, education, gender, marital status, health insurance, and employment status) at baseline and 8 weeks.

Despite the significant prevalence and burden of postpartum psychological distress, existing interventions remain underused, particularly among historically marginalized groups who face systemic barriers to care. While evidence-based psychotherapies such as CBT and IPT are effective in treating postpartum mood disorders, there is a critical need to explore how these interventions can be feasibly and equitably delivered to diverse populations in nonclinical settings. Digital health tools, such as mobile applications, hold immense promise for addressing these gaps by overcoming logistical and stigma-related barriers. However, few digital interventions have been rigorously studied in postpartum populations. By evaluating the feasibility, acceptability, and preliminary efficacy of W-PPMA in a diverse and bilingual cohort, this study aims to advance understanding of scalable, accessible mental health solutions. Ultimately, this research provides critical insights into closing the postpartum mental health treatment gap with an emphasis on equity and inclusion.

Methods

Ethical Considerations

This study was approved as human participants research by the Institutional Review Board (IRB) of the Scripps Research Translational Institute (IRB-21‐7738). This study was conducted at the Scripps Research Translational Institute. All participants provided informed e-consent before participation. Deidentified data were transferred to the Scripps Research Translational Institute for analysis.

Study Design

This randomized waitlist-controlled trial evaluated the W-PPMA digital health tool. The trial consisted of 3 phases: screening/baseline, treatment, and follow-up. Participants were assessed at screening/baseline, day 3, week 4, week 8 (EOI), week 12, and week 16 (end of study [EOS]). The day 3 assessment was included to capture early usability and engagement signals, as well as to verify baseline stability immediately post randomization. All primary end points were evaluated at week 8 (EOI). A waitlist control design was selected to balance methodological rigor with ethical considerations. This approach allowed all participants eventual access to W-PPMA after the 8-week EOI assessment, thereby minimizing the risk of withholding potentially beneficial support from a vulnerable postpartum population. The design was reviewed and approved by the IRB as consistent with ethical standards for studies involving mental health interventions.

Recruitment Strategy

Pregnant and postpartum participants were recruited through the PowerMom baseline research study (Scripps Research Digital Trials Center), a mobile app-based research initiative hosted on the HIPAA (Health Insurance Portability and Accountability Act)–compliant MyDataHelps (CareEvolution, LLC) clinical research platform. PowerMom enables participants to access prenatal health resources while contributing pregnancy-related data to research. Recruitment for PowerMom was supported by a bilingual, multichannel campaign (eg, email, social media, and in-app nudges) involving PowerMom Consortium [30] partners from health and technology organizations, maternal advocacy groups, and community health centers. Key partners included Microsoft, Google/Fitbit, Philips, March of Dimes, and others, and community-based organizations serving Black and Hispanic/Latina populations. Recruitment campaigns outside of consortium partners also included Ovia Health (Labcorp) platform.

English-speaking PowerMom participants received information about the Woebot substudy through email and in-app notifications. Interested PowerMom participants who were in the postpartum period were directed to the Woebot eligibility screening, which included a disclaimer about the sensitive nature of some questions. Eligible participants provided informed consent for the Woebot substudy, and participation in the Woebot substudy did not affect their involvement in the PowerMom baseline study.

The recruitment period for the Woebot substudy was from February 2023 to January 2024. The initial goal was to recruit

XSL•FO
RenderX

225 participants in each arm of this study. To promote inclusivity, recruitment aimed to enroll at least 30% of participants from underrepresented racial and ethnic groups and 50% from groups underrepresented in biomedical research (UBRs), as defined by the NIH (National Institutes of Health) All of Us Research Program [31]. UBR criteria included racial/ethnic minorities, low socioeconomic status, rural residency, and other categories. To achieve this distribution, the UBR criteria were built into the enrollment workflow in this study's app. This study's app was configured such that enrollment would be paused for any non-UBR participant until we had reached 225 enrolled and consented participants who self-identify from a UBR race or ethnicity or other UBR category. A study coordinator actively monitored enrollment numbers to ensure recruitment targets were being met.

However, the sponsor nominated to end enrollment early (after n=296 consented) given that the a priori goal of sample diversity (50% UBR) was successfully achieved early and also to advance time to results given the importance and relevance of the hypotheses tested herein. The original sample size target (n=450) was selected to provide approximately 80% power to detect a small-to-moderate effect size (Cohen $d \approx 0.30$) in change in depressive symptoms (Patient Health Questionnaire–8 [PHQ-8]) at $\alpha = .05$. Given early closure of enrollment, the final analytic sample (N=267) was underpowered for efficacy analyses, and these outcomes are presented as exploratory.

Inclusion and Exclusion Criteria

Eligible participants were PowerMom enrollees aged 16 years or older, less than 3 months postpartum, English-literate, smartphone users, and willing to engage with the program and assessments for 16 weeks.

Exclusion criteria included a lifetime diagnosis of psychotic or bipolar disorders, suicidal ideation or attempts within the past 12 months, substance use within the past 12 months, pregnancy loss in the past 18 months, or prior use of Woebot programs.

Procedures

Participation spanned 16 weeks, including an 8-week intervention or waitlist control period, followed by exploratory assessments at 12- and 16-weeks. After completing baseline assessments, participants were randomized 1:1 into the W-PPMA group or the waitlist control group. Neither participants nor staff were blinded to group assignments.

Participants randomized to W-PPMA accessed the app from randomization through 16 weeks (EOS) and were encouraged to use it daily, with a recommended minimum of 5 minutes per day during the treatment phase. Waitlist participants accessed W-PPMA starting at 8 weeks (EOI). Assessments were conducted via the PowerMom app at baseline, day 3, 4-week, 8-week (EOI), 12-week, and 16-week (EOS) time points. Each assessment took 10 - 15 minutes, and participants received reminders via email and PowerMom app push notifications.

Participants were eligible to receive up to US $175 in Amazon e-gift cards as compensation, prorated across completion of scheduled study assessments (eg, baseline, midintervention, EOI, and follow-up surveys). The compensation schedule was designed to acknowledge participant time burden across multiple assessments and to support retention over the 16-week study period while remaining modest to minimize undue inducement; the amount and structure were reviewed and approved by the IRB and were consistent across all participants to ensure fairness and transparency. Gift cards were distributed electronically after the completion of each assessment time point. During enrollment, fraudulent activity was detected, characterized by anomalous enrollment patterns (eg, implausibly rapid e-consent and survey completion times and duplicate IP addresses) and an unusual and rapid spike in enrollment across both the baseline study and the Woebot substudy. A small number of fraudulent accounts received e-gift card links before being identified. To ensure data integrity, all fraudulent enrollments were excluded before randomization, and participants who failed to complete baseline assessments were classified as screen failures and not included in this study. Only verified participants who met all eligibility criteria and completed baseline assessments were randomized. The final analytic sample (N=267) excluded all fraudulent accounts and therefore represents postpartum individuals meeting the intended inclusion criteria.

Intervention Groups

W-PPMA

W-PPMA is an investigational DMHI that offers an 8-week guided self-help program that combines CBT- and IPT-based techniques tailored to provide mental health support to postpartum women. Through a text-based interface, a relational agent named Woebot engages users in conversations and provides users with self-guided psychoeducation and mood and anxiety management strategies. The program includes daily push notifications to reengage users and encourage consistent participation. Neither W-PPMA nor Woebot have been evaluated, cleared, or approved by the Food and Drug Administration and are not available for general use.

Waitlist Control

Waitlist control participants had access to W-PPMA from the 8-week (EOI) through to the 16-week (EOS) period with similar usage recommendations.

Safety Considerations

W-PPMA followed safety recommendations from the American Psychiatric Association [32] and American Medical Association [33]. W-PPMA has a language detection protocol that is based on a natural language processing algorithm designed to detect if a user inputs, via free-response text entry, concerning phrases or words that match an a priori identified and thorough list that may be used in crises. Upon detection of any concerning language, the language detection protocol reminds the participant of the app's limitations of services—which are stated in the study's informed consent, the W-PPMA mobile app's privacy policy and terms of service, as well as the intervention's onboarding screens—and offers a resource list of readily accessible support channels, including emergency contact phone numbers and suicide ideation and domestic violence hotline information.

XSL•FO
RenderX

Additionally, in the event that a participant endorses having current suicidal ideation or a plan when answering the screening questions, an automatic email would be sent to this study's team. Study personnel would then call 911, notify the operator that it is a psychiatric emergency, and provide a trained emergency response person with the participant's phone number to follow up with them. All participants were informed of these procedures in this study's consent form, which explicitly outlined the protocol for responding to safety concerns, including emergency escalation and study personnel involvement in crises.

Assessments

Baseline assessments collected demographic data, including age, race, ethnicity, gender identity, marital status, education, employment, and insurance status. Neighborhood socioeconomic disadvantage was assessed using the Area Deprivation Index (ADI) from the Neighborhood Atlas, which ranks census block groups nationwide by socioeconomic disadvantage, with higher scores indicating greater disadvantage. Pregnancy history included the number of prior pregnancies, outcomes, and any fetal demise within the exclusionary period. Psychiatric history assessed diagnosis of psychotic disorders, mood disorders, and suicidality within the past 12 months, and substance use during the same period. Current or prior use of psychiatric medications and therapy was also documented.

Primary Outcomes: Feasibility, Acceptability, and Satisfaction Measure

Regarding Usage Rating Profile–Intervention Revised (URP-IR) [34], the 6-item feasibility (Usage Rating Profile–Intervention Revised, Feasibility Subscale [URPI-F]) and 6-item acceptability (Usage Rating Profile–Intervention Revised, Acceptability Subscale [URPI-A]) subscales were used to measure feasibility (eg, "The total time required to do the treatment procedures was manageable") and acceptability (eg, "I liked the procedures used in this treatment"). Responses ranged from 1 ("strongly disagree") to 6 ("strongly agree"), with total scores ranging from 6 to 36 and higher average scores indicating greater feasibility or acceptability. The URP-IR demonstrates strong reliability, internal consistency, and discriminant validity [34].

Regarding Client Satisfaction Questionnaire (CSQ-8) [35], this widely used 8-item measure evaluated participants' satisfaction with W-PPMA on a 4-point scale (eg, "How would you rate the quality of service you received?"). Total scores ranged from 8 to 32, with higher scores indicating greater satisfaction.

Regarding app engagement, engagement with the W-PPMA app was assessed using quantitative metrics, including the number of active days, messages sent per week, and the number of content modules completed.

For interpretability, thresholds were applied to define high feasibility, acceptability, and satisfaction. On the URPI-F and URPI-A subscales (range 6 - 36), scores ≥30 were considered indicative of strong feasibility or acceptability. On the CSQ-8 (range 8 - 32), scores ≥25 were considered indicative of high satisfaction. These thresholds are consistent with prior applications of these validated instruments.

Secondary Outcome: Symptoms of Depression

The PHQ-8 is an 8-item measure evaluating depressive symptom severity over the past 2 weeks [36]. Scores range from 0 to 24, with cut points of 5, 10, 15, and 20 corresponding to mild, moderate, moderately severe, and severe depression, respectively [37,38]. The PHQ-8 is a reliable and valid tool for screening depressive symptoms [39].

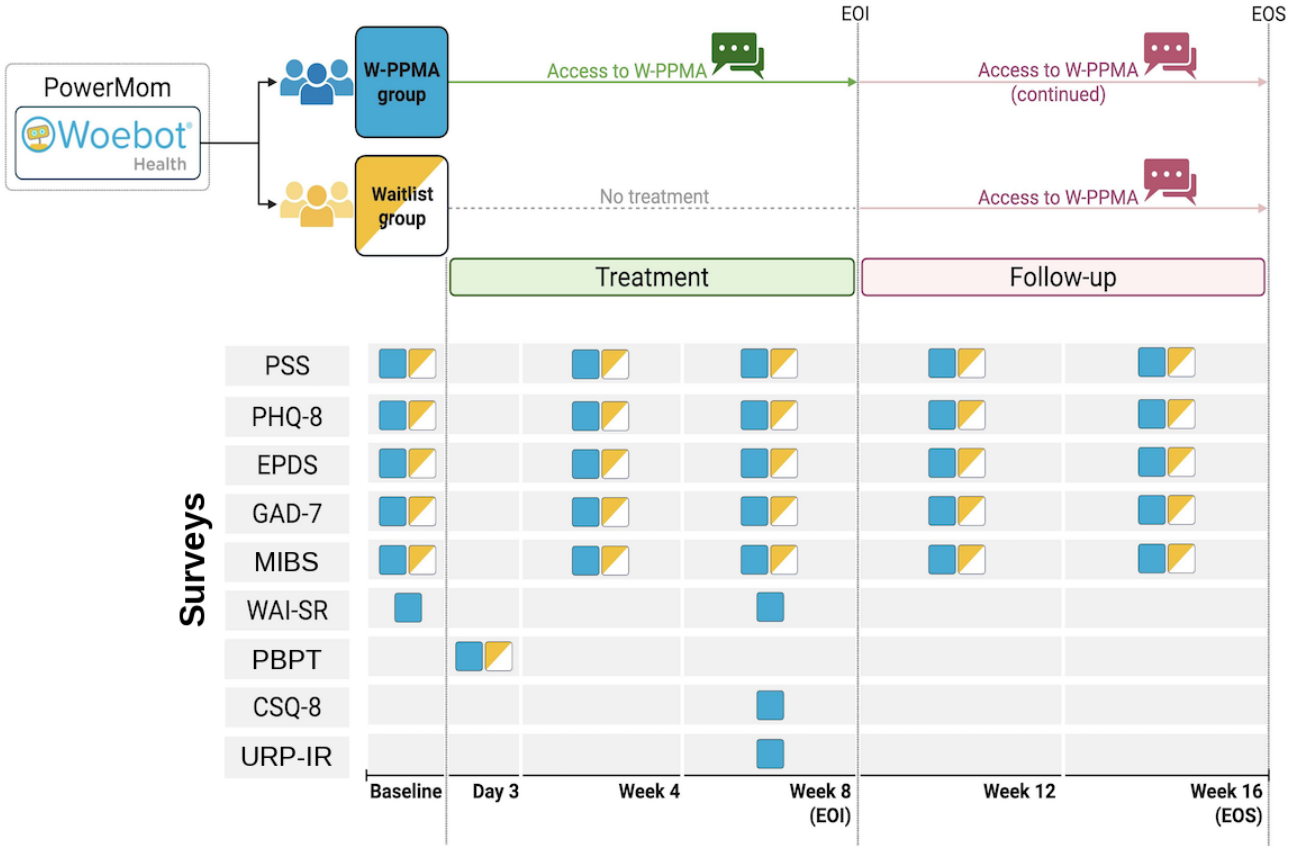
Exploratory Outcomes

The Edinburgh Postnatal Depression Scale (EPDS) is a 10-item self-report tool that screens for postnatal depression [40]. For this study, the suicidality item was omitted; therefore, 9 items were administered and the total score ranged from 0 to 27, with higher scores indicating greater depressive symptom severity. The EPDS is widely validated for postpartum populations [41]. Both the PHQ-8 and EPDS were included to capture depressive symptoms: the PHQ-8 is widely validated for general populations and aligned with our primary depression outcome, while the EPDS is specific to perinatal populations and allows comparability with prior postpartum research.

Regarding Generalized Anxiety Disorder (GAD-7), the GAD-7 is a 7-item measure assessing anxiety symptoms over the past 2 weeks [42]. Scores range from 0 to 21, with cut points of 5, 10, and 15 indicating mild, moderate, and severe anxiety, respectively. This measure has demonstrated high reliability and validity [43].

Regarding Perceived Stress Scale–10, this 10-item scale measures perceived stress in the past month [44]. Responses range from 0 ("never") to 4 ("very often") and scores range between 0 and 40, with higher scores indicating greater perceived stress. The Perceived Stress Scale–10 demonstrates strong reliability and validity [45].

Regarding the Mother-to-Infant Bonding Scale (MIBS), the MIBS includes 8 one-word emotional descriptors (eg, "loving" or "resentful") rated on a 4-point scale from 0 ("very much") to 3 ("not at all"). Total scores range from 0 to 24, with lower scores indicating stronger mother-to-infant bonding [46,47].



Regarding the Working Alliance Inventory–Short Revised (WAI-SR), the 12-item WAI-SR measures therapeutic alliance using 3 subscales: task agreement, goal agreement, and affective bond [48]. Items were adapted to refer to Woebot as the therapist. Responses range from 1 ("never") to 5 ("always"), with higher scores indicating a stronger therapeutic alliance.

Regarding Perceived Barriers to Psychological Treatment (PBPT), the PBPT [49] identifies potential barriers to engaging in mental health treatment. This study used the 7-item Stigma subscale (eg, "My concern about being judged makes it ____ for me to attend counseling"), with responses ranging from 1 ("not difficult at all") to 5 ("impossible").

Figure 1 presents the schedule of assessments by study group.

XSL•FO
RenderX

Figure 1. Schedule of assessment. Time point where each outcome measure was administered and whether this was for all participants or only those in the W-PPMA group. Week 8 represents EOI, after which the waitlist control group additionally gained access to the Woebot app. CSQ-8: Client Satisfaction Questionnaire-8 items; EOI: end of intervention; EOS: end of study; EPDS: Edinburgh Postnatal Depression Scale; GAD-7: Generalized Anxiety Disorder Scale; MIBS: Mother-to-Infant Bonding Scale; PBPT: Perceived Barriers to Psychological Treatment, Stigma Subscale; PHQ-8: Patient Health Questionnaire–8; PSS: Perceived Stress Scale; URP-IR: Usage Rating Profile–Intervention Revised; W-PPMA: Woebot for Postpartum Mood and Anxiety; WAI-SR: Working Alliance Inventory–Short Revised.

Statistical Analysis

Primary analyses were conducted using an intention-to-treat strategy whereby participants were analyzed in the treatment group to which they were assigned. Per protocol (PP) sensitivity analyses were performed for the CSQ-8, URPI-A, URPI-F, PHQ-8, GAD-7, EPDS, Perceived Stress Scale (PSS), MIBS, and WAI-SR outcome measures. These sensitivity analyses excluded participants who deviated from the protocol in one or more of these ways: relevant measures not completed in full within the preplanned timing window, withdrew from this study, and, if in the W-PPMA group, did not open the app at least once per week for at least half of the intervention weeks. The latter criterion was based on previous research into app usage patterns.

Sample characteristics, including participant self-reported sociodemographic, psychiatric, and pregnancy history, and prior and concomitant medications and therapy characteristics, were described overall and by intention-to-treat study group.

The primary outcomes of feasibility, acceptability, and satisfaction were described for the W-PPMA study group at the 8-week time point (EOI).

The secondary outcome to assess the preliminary efficacy of W-PPMA relative to a waitlist control condition to manage symptoms of depression was analyzed among the subgroup of participants with PHQ-8 greater than or equal to 5 at baseline (minimal to several symptoms of depression). Mean 8-week change scores were calculated and compared using a 2-sided independent *t* test. Cohen *d* effect size was also calculated. Preplanned sensitivity analyses for this outcome included (1) PP sensitivity analysis as described above, (2) comparing 8-week scores instead of change scores, (3) multiple linear regression to adjust for potential residual confounding by baseline covariates (age, race, psychotherapy at baseline, mental health medication at baseline, previous PPD diagnosis, and previous depression diagnosis), and (4) describing scores by clinical categories. Bonferroni adjustment of *P* values was performed to account for the 4 statistical tests (primary and first 3 sensitivity) run on the PHQ-8 outcome.

The exploratory outcomes for preliminary assessment of mood and efficacy (PSS, EPDS, GAD-7, and MIBS) were summarized at each time point with Cohen *d* to assess group differences. Change scores from baseline to 8 weeks were additionally compared and summarized using the mean difference with 95% CI. Exploratory outcomes of therapeutic bond were summarized at baseline and 8-weeks.

Exploratory stratified analyses were performed to describe outcomes and the measure of perceptions of stigma by strata of age, Hispanic/Latina ethnicity, racial background, marital status, sexual orientation, employment status, education, health insurance, and neighborhood atlas. To maintain a high enough sample size for meaningful grouping, within each stratification

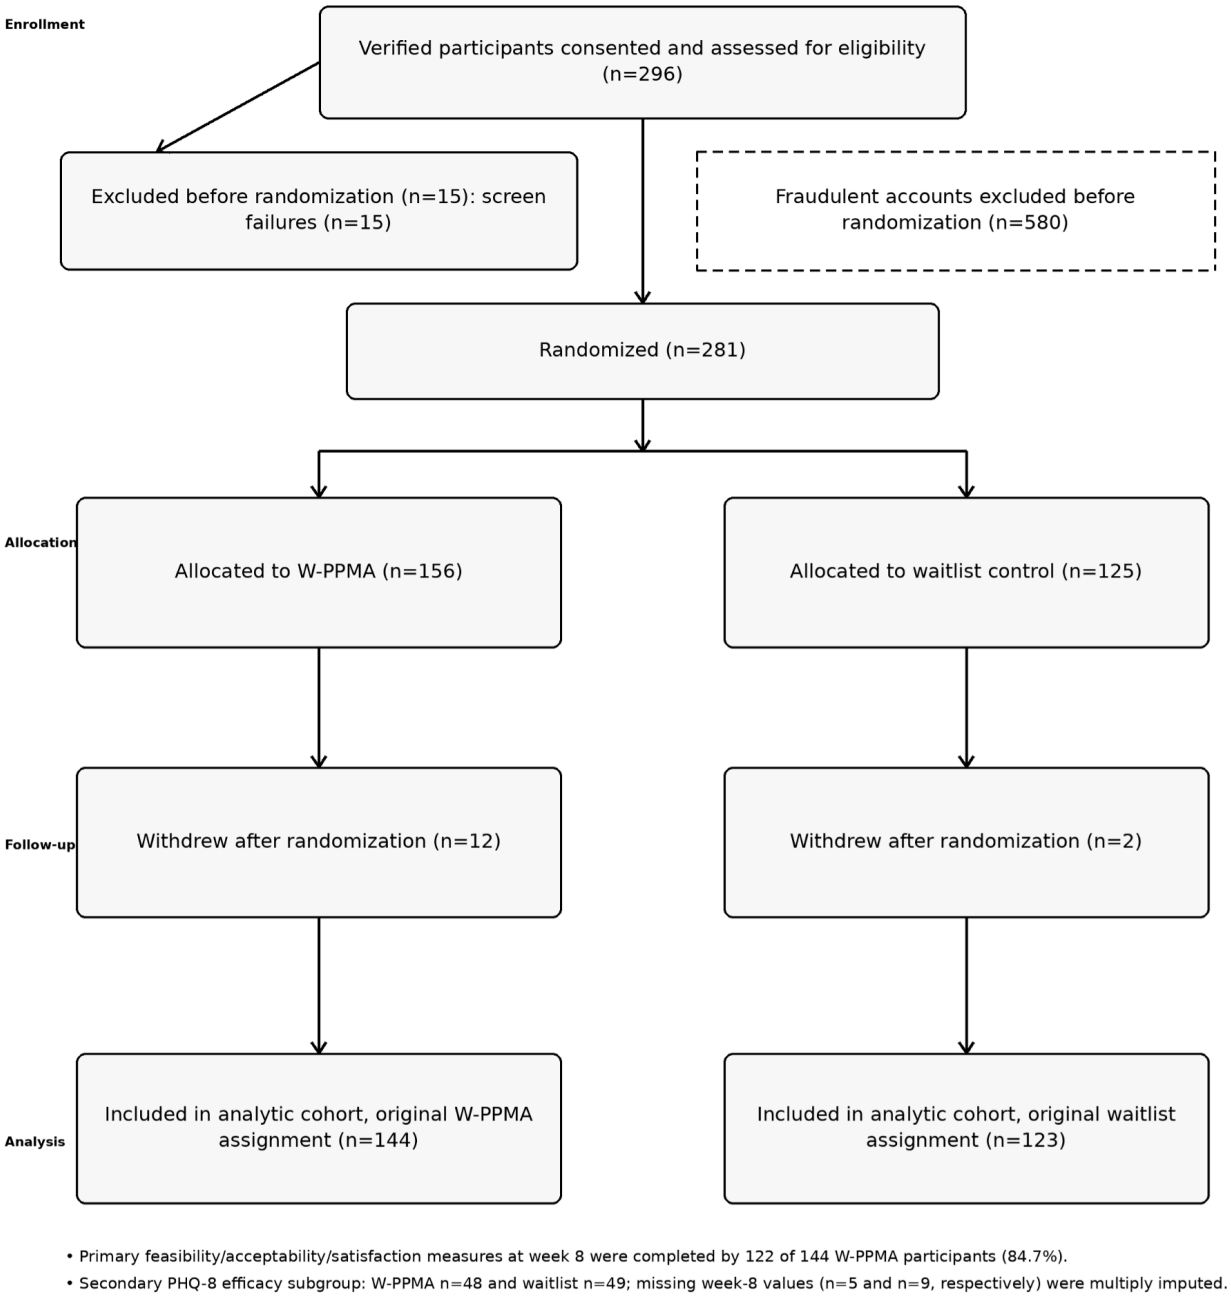
XSL•FO
RenderX

some response options were grouped or removed. While grouping removes some important between-group differences, we opted to do this to be able to share some information rather than excluding minority groups altogether. Due to variability in circumstances related to being a student, we do not report student strata for employment and education analyses.

Missing Data

For the primary between-group comparison of treatment effect size (secondary outcome PHQ-8), we used multiple imputation to complete any missing PHQ-8 scores to minimize potential bias from missing data. Multiple imputation by chained equations was performed using the miceforest library (version 6.0.3) [50] with the default random forests predictive model. Covariates were the same as for the multiple regression analysis, with missing data in these additionally imputed as needed: study group, age, race, psychotherapy at baseline, mental health medication at baseline, previous PPD diagnosis, and previous depression diagnosis. For single-group and exploratory outcome analyses, where the analytical goals were more descriptive or preliminary, participants who did not complete a measure in full at any given time point were excluded from pertinent analyses. We report the number of participants included at each time point for each measure.

For descriptive analyses, measures were summarized by mean and SD or by median and IQR, whether normally distributed or not, respectively. Analyses were completed in Python (version 3.8).



Results

Study Sample

Of 296 participants who consented, 15 (5.1%) were screen failures, and 14 (4.7%; W-PPMA: n=12, waitlist: n=2) withdrew from this study, leaving 267 participants (W-PPMA: n=144, waitlist: n=123) for analyses. There were an additional 580 fraudulent accounts detected and removed; these accounts were identified through study monitoring procedures (eg, anomalous completion times and duplicate IP addresses) and were excluded before randomization and from all analyses (Figure 2). Table 1 shows participant self-reported sociodemographic characteristics overall and by treatment group. Overall, the mean participant age was 32.2 (SD 5.1; range 16.3-48.7)years; all 267 participants identified as women, 34 (12.7%) identified as Hispanic/Latina, and 183 (68.5%) identified as White. After randomization, the W-PPMA and waitlist groups were similar on most characteristics, with notable exceptions that a greater proportion of the W-PPMA group was Hispanic/Latina (23/144, 16%, vs 11/123, 8.9%) and identified with multiple races (24/144, 16.7% vs 11/123, 8.9%) whereas the waitlist group had a higher proportion of White participants (90/123, 73.2%, vs 93/144, 64.6%), participants with a college degree (46/123, 37.4%, vs 39/144, 27.1%), and participants with an ADI ranking of at least 75 (14/123, 11.4% vs 7/144, 4.9%).

[a]The one participant missing age value answered the screening questionnaire to confirm they were aged 16 years or older but did not provide their exact date of birth.

[b]W-PPMA: Woebot for Postpartum Mood and Anxiety.

[c]Indicates participants who self-identified their race as Hispanic/Latina in addition to their ethnicity as Hispanic/Latina.

[d]VA: Veterans Affairs.

[e]ADI_Natrank: Area Deprivation Index–National Rank; derived from the Neighborhood Atlas; higher scores indicate greater neighborhood disadvantage.

Table 2 shows psychiatric and pregnancy history. Overall, 31/267 (11.6%) participants self-reported a previous PPD diagnosis and 113/267 (42.3%) a previous depression diagnosis. At study baseline, 41/267 (15.4%) of participants reported engaging in psychotherapy and 67/267 (25.1%) taking a mental health medication. The number of past pregnancies ranged from 0 to over 5, and regarding participants' most recent pregnancy, 38/267 (14.2%) participants had their child spend time in the neonatal intensive care unit, and 22/267 (8.2%) participants reported receiving a medical and/or genetic disorder diagnosis.

[a]W-PPMA: Woebot for Postpartum Mood and Anxiety.

[b]OB/gyn: obstetrician/gynecologist.

[c]NICU: neonatal intensive care unit.

Primary Outcomes: Feasibility, Acceptability, and Satisfaction

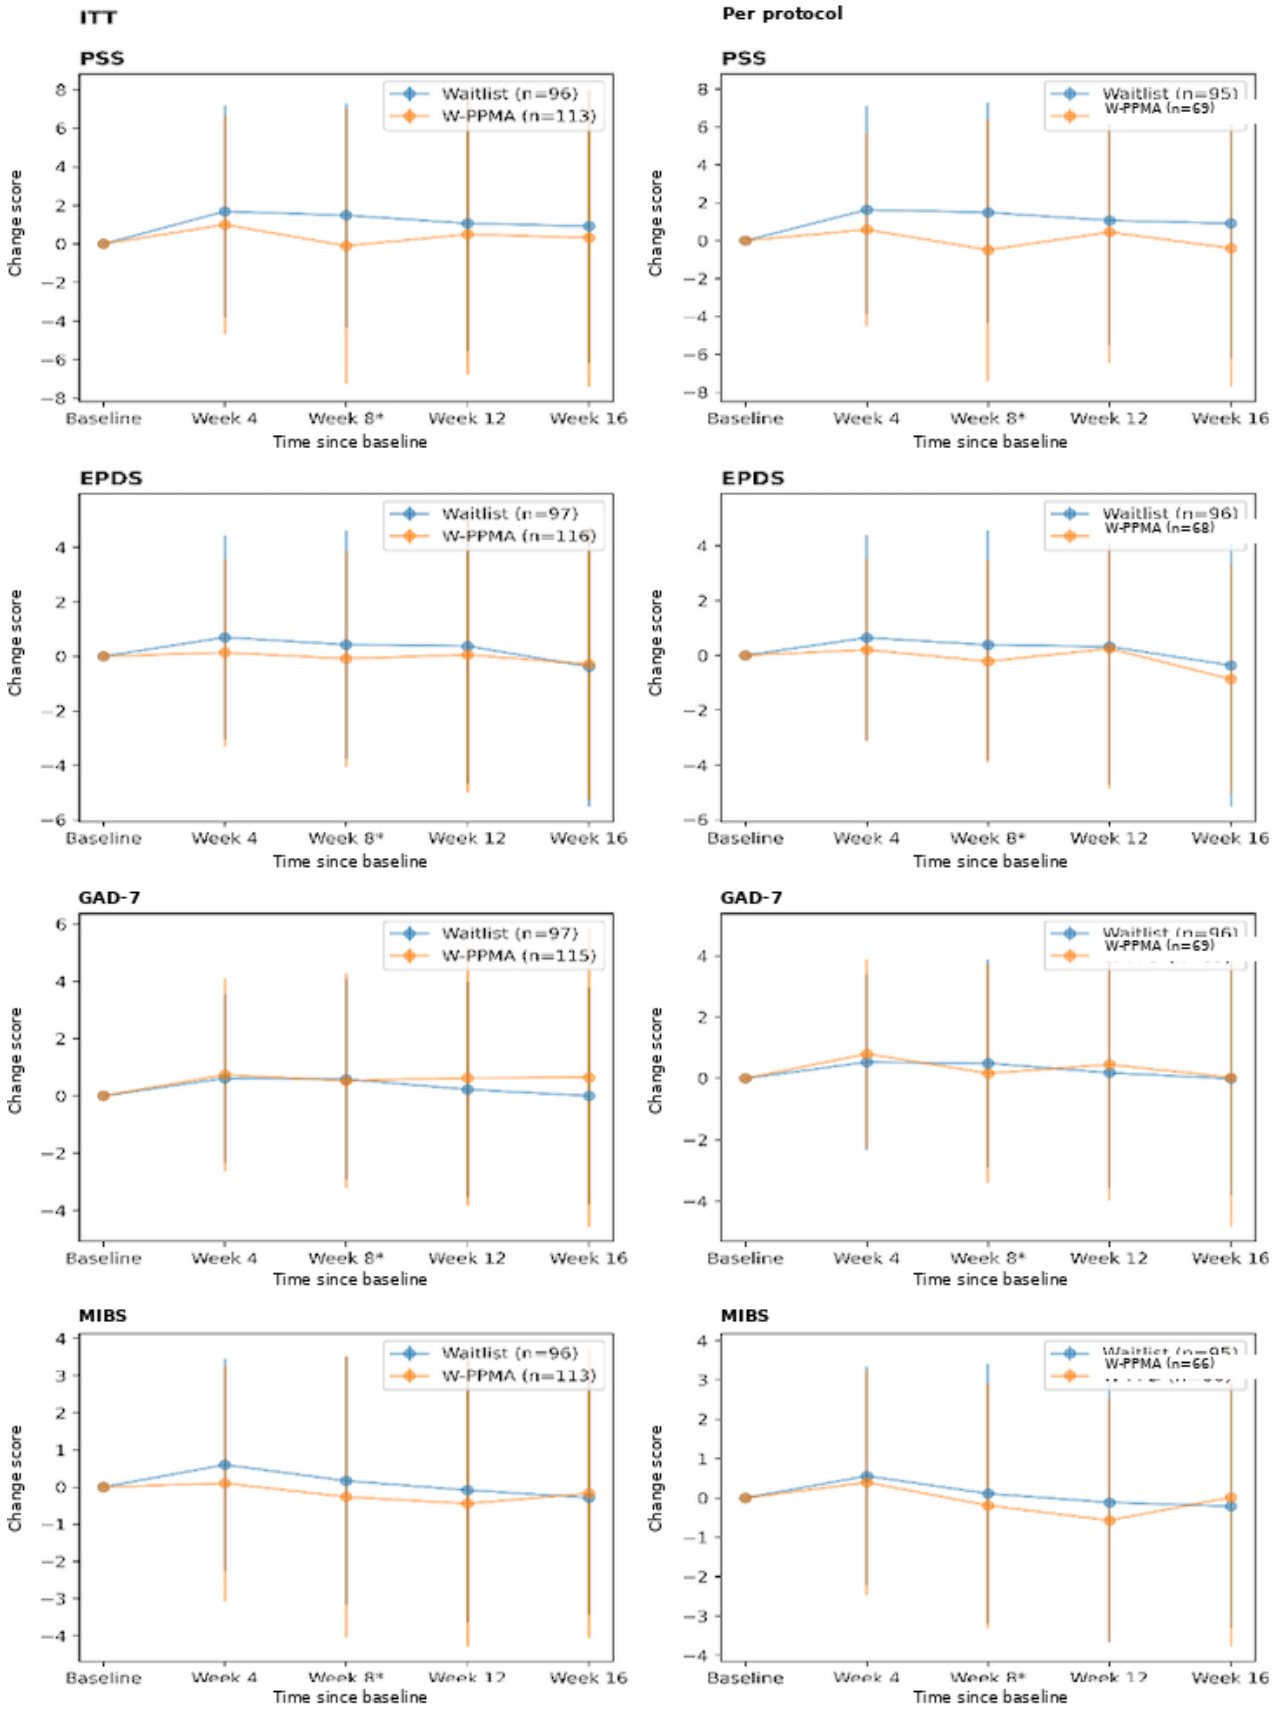
Table 3 shows app engagement metrics. Across the 8-week intervention, the median number of days that participants used W-PPMA was 9.0 (IQR 5.0-23.8) and 4.0 (IQR 2.0-7.0) active weeks. Participants sent a median of 217 (IQR 89-688) in-app messages and completed 6.0 (IQR 2.3-18.8) stories and 1.5 (IQR 1.0-3.0) tools.

Table . Woebot app engagement metrics**.** These are the primary outcome measures of app engagement among the W-PPMA[a] group for the initial 8-week treatment period. As the W-PPMA user experience is tailored entirely to the user's input, there is no a priori set number of stories and/or tools a user must complete; rather, each conversation with Woebot is adapted to the user in the moment with as-needed offering of stories and/or tools.

Engagement metric	Values, median (IQR)
Active days	9.0 (5.0-23.8)
Active weeks	4.0 (2.0-7.0)
Messages sent by user	217 (89-688)
Stories completed	6.0 (2.3-18.8)
Tools completed	1.5 (1.0-3.0)
Tools rated	1.0 (0.0-2.0)

[a]W-PPMA: Woebot for Postpartum Mood and Anxiety.

Of the intention-to-treat W-PPMA group, 122/144 (84.7%) completed the 8-week (EOI) measures for acceptability, feasibility, and satisfaction. The median score for URPI-F was 31.0 (IQR 28.0-34.0), for URPI-A was 30.0 (IQR 28.0-34.0), and for CSQ-8 was 26.0 (IQR 24.0-29.0). Score distributions are presented in Figure S1 in Multimedia Appendix 1. Slightly higher scores were seen in the PP sensitivity analysis that included 76/144 (52.8%) of the W-PPMA group, with median scores of 32.0 (IQR 29.0-36.0) for URPI-F, 31.5 (IQR 28.0-35.2) for URPI-A, and 27.0 (IQR 24.0-29.2) for CSQ-8.



Secondary Outcome: Symptoms of Depression (PHQ-8)

There were 97 participants (n=48 W-PPMA, n=49 waitlist) with a baseline PHQ-8 score of at least 5, the minimal total score of the PHQ-8 indicating the presence of at least mild symptoms of depression. Multiple imputation was used to impute missing 8-week PHQ-8 scores for 14 participants (n=5 W-PPMA, n=9 waitlist). Overall mean change in PHQ-8 from baseline to EOI was −0.3 (SD 4.2), whereby W-PPMA averaged slight improvement (−0.7, SD 3.4) and the waitlist group averaged no change (0.0, SD 4.8). The between-group effect size was small (Cohen *d* −0.16) and not statistically significant after adjustment for multiple testing ($P \geq .99$). The PP sensitivity analysis showed a greater separation of groups (W-PPMA: −1.4, SD 3.5, waitlist: 0.7, SD 3.9, adjusted $P=.13$) with medium effect size (Cohen *d* −0.57). Figure 3 shows the distribution of change scores for the intention-to-treat and PP subgroups.

XSL•FO
RenderX

Figure 3. Change scores for exploratory mood and preliminary efficacy measures. Mean and SD of change scores at each time point relative to the baseline overall and by treatment group. To support interpretation in the context of the established measures, scores are presented in the original units and should not be directly compared between scales, as a 1-point change represents a different percentage change across scale ranges (PSS: 0 - 40, EPDS: 0 - 27, GAD-7: 0 - 21, MIBS: 0 - 24). The asterisk indicates the 8-week end-of-intervention point after which the waitlist group gained access to the intervention. The number in each legend is the minimum number of participants included across all time points. EPDS: Edinburgh Postnatal Depression Scale; GAD-7: Generalized Anxiety Disorder Scale; ITT: intention-to-treat; MIBS: Mother-to-Infant Bonding Scale; PSS: Perceived Stress Scale; W-PPMA: Woebot for Postpartum Mood and Anxiety.

XSL•FO
RenderX

Additional planned sensitivity analyses produced similar patterns, but neither analysis was statistically significant: the comparison of week-8 EOI scores had an adjusted *P* value of .38, and the adjusted regression analysis had an adjusted *P* value of .96. Comparison of the 8-week EOI scores alone showed lower average symptoms in the W-PPMA (mean 6.9, SD 3.4) than waitlist (8.4, SD 5.1) group (Cohen *d* −0.48, adjusted *P*=.38). Multiple regression analyses to adjust for potential

XSL•FO
RenderX

residual confounding by baseline characteristics found access to W-PPMA was associated with a 1-point reduction in PHQ-8 change score as compared to the waitlist control group (95% CI −2.69 to 0.69, adjusted *P*=.96). All regression coefficients are presented in Table S1 in Multimedia Appendix 1. Examining PHQ-8 scores by clinical category showed similar distributions at baseline and descriptively lower severity in the W-PPMA group than in the waitlist group; no P value was reported for this descriptive comparison (Table S2 in Multimedia Appendix 1). Intention-to-treat results indicated that among those with elevated symptoms at baseline, 9/48 (18.8%) W-PPMA and 9/49 (18.4%) waitlist participants improved by at least 4 points. In the PP subgroup, 7 W-PPMA participants and 5 waitlist participants improved by at least 4 points.

Exploratory Outcomes: Postnatal Anxiety (GAD-7), Depression (EPDS), Stress (PSS), MIBS, and Therapeutic Bond (WAI-SR)

Preliminary mood and efficacy measures. Table 4 displays the median (IQR) scores with Cohen *d* between-group effect size for each exploratory outcome at each time point. The PSS and EPDS showed small between-group effect sizes in favor of W-PPMA at 4-, 8-, and 12-week points. By the 16-week EOS point, differences had mostly disappeared, driven by a reduction in waitlist scores, while the W-PPMA scores stayed relatively stable after 8-weeks; the waitlist group had access to the app from 8-weeks to 16-weeks while the W-PPMA group had access for the full 16-weeks. There were very small or no differences between W-PPMA and waitlist groups across all time points for the GAD-7 and MIBS. Participant counts by measure and time point are reported in Table S3 in Multimedia Appendix 1. In the PP sensitivity analyses, differences were not statistically significant but were descriptively larger than in the primary intention-to-treat analysis, with the largest effect observed for the PSS at EOI (Cohen *d*=−0.47; Table S4 in Multimedia Appendix 1). Figure 3 shows the change scores for each measure across this study's period. The mean difference from baseline to EOI was −1.59 (95% CI −2.4 to −0.73) for PSS, −0.51 (95% CI −1.36 to 0.34) for EPDS, −0.05 (95% CI −0.91 to 0.80) for GAD-7, and −0.43 (95% CI −1.28 to 0.42) for MIBS. For all measures except MIBS, the difference was larger in favor of W-PPMA in the PP sensitivity analyses (Table S4 legend in Multimedia Appendix 1)

Therapeutic Bond. The WAI-SR median score was 42.0 (IQR 36.0-51.0) at baseline among the 94/144 (65.3%) W-PPMA participants who completed it, and increased to 48.0 (IQR 41.0-53.0) at EOI among the 113/144 (78.5%) who completed it at the second time measure. PP sensitivity analysis scores were similar (baseline: 43.0, IQR 37.0-51.0, with n=54, week 8: 51.0, IQR 45.0-54.8, with n=70).

[a]W-PPMA: Woebot for Postpartum Mood and Anxiety.

[b]PSS: Perceived Stress Scale.

[c]EPDS: Edinburgh Postnatal Depression Scale.

[d]GAD-7: Generalized Anxiety Disorder Scale.

[e]MIBS: Mother-to-Infant Bonding Scale.

Exploratory Analyses: Stratified Analyses

Perceptions of Stigma

The overall baseline PBPT-Stigma Subscale score median was 12.0 (IQR 9.0-15.0), similar in W-PPMA (12.0, IQR 9.0-14.0) and waitlist (11.0, IQR 10.0-15.0) groups at baseline. Variation across strata was within 2 points. The highest point estimate was among the racial background strata of Hispanic/Latina (14.0, IQR 13.8-15.2) and those who did not have health insurance (14.0, IQR 11.5-17.5). The lowest point estimates were among those employed part time (10.0, IQR 8.0-13.5) and with military health insurance (10.0, IQR 9.0-11.5; Table S5 in Multimedia Appendix 1).

Usability and Acceptability Measures

The median URPI-F score was similar across strata, with the lowest median scores being 2 points below the overall median among those not employed and with ADI ranking 75 and above,

XSL•FO
RenderX

and 5 points lower than the overall median among those without health insurance. Two overall strata had median scores 2 points higher, including military health care insurance and those with high school or General Educational Development (GED) education. The URPI-A had a wider range of scores across strata, with a median score 6 points above the overall median among those single, separated, or divorced and 5 points higher among ADI ranking 75 and above; and a median 6 points below the overall median among those without health insurance. The CSQ-8 had the highest median score among those with a high school or GED education and lowest among those without health insurance. All stratified usability and acceptability measure scores, including by study subgroups, are in Table S6 in Multimedia Appendix 1.

Preliminary Mood and Efficacy Measures

The PSS baseline scores were highest among those who reported being Black, not employed, or not having health insurance. The EOI scores were highest among those who reported being Asian, Hispanic/Latina, or not employed (Table S7 in Multimedia Appendix 1). EPDS baseline scores were highest among those who reported being Black and without health insurance, with week 8 scores additionally highest among those who reported being Black or not employed (Table S8 in Multimedia Appendix 1). GAD-7 and MIBS median scores among the entire cohort were within 2 points across all strata (Tables S9 and S10, respectively, in Multimedia Appendix 1). WAI-SR scores were highest among Black participants, and ADI ranking of at least 75 strata at baseline and among those with military health insurance or ADI ranking of at least 75 at week 8 (Table S11 in Multimedia Appendix 1).

Discussion

Principal Results

In this study, we assessed the feasibility, acceptability, and preliminary efficacy of the W-PPMA intervention to provide emotional support among a diverse and bilingual cohort. The results demonstrated high feasibility and acceptability among participants, as evidenced by strong scores on the URP-IR and CSQ-8. The intervention achieved notable engagement, with participants using W-PPMA for a median of 9 (IQR 5 - 24) days and sending a median of 217 (IQR 89-688) messages across the 8-week intervention period.

The primary PHQ-8 outcome showed a small, nonsignificant effect in the intention-to-treat analysis (Cohen d=−0.16; P≥.99). Among exploratory outcomes at EOI, the between-group difference in PSS change favored W-PPMA and had a 95% CI that excluded 0 (mean difference −1.59, 95% CI −2.4 to −0.73), whereas the EPDS difference was not statistically significant (mean difference −0.51, 95% CI −1.36 to 0.34). Participants in the W-PPMA group had a statistically significant improvement in perceived stress relative to the waitlist control group at EOI; the between-group difference in EPDS scores was not statistically significant. PP analyses indicated moderate effect sizes, particularly for perceived stress, highlighting the potential of W-PPMA in reducing postpartum psychological distress. Therapeutic bonding with Woebot was also positively rated, suggesting the relational agent's ability to foster a supportive user experience.

Despite challenges in achieving the full recruitment target in a timely fashion, this study successfully enrolled a diverse cohort of postpartum individuals, ensuring representation of underrepresented racial, ethnic, and socioeconomic groups. Notably, W-PPMA demonstrated strong engagement across these diverse populations, reinforcing its promise as a scalable and inclusive intervention. The findings further support W-PPMA's potential to foster positive therapeutic engagement among groups historically underrepresented in digital health research. For example, working alliance (WAI-SR) scores were highest among Black participants and those residing in the most socioeconomically disadvantaged neighborhoods (ADI ≥75) at baseline. By week 8, Hispanic/Latina participants, those of multiple racial backgrounds, and those in areas with an ADI ranking of at least 75 demonstrated the highest WAI-SR scores, suggesting that W-PPMA effectively engaged these populations over time.

Additionally, participant satisfaction with W-PPMA was notably high among those with a high school or GED, as indicated by the CSQ-8 scores. This underscores W-PPMA's accessibility and acceptability among individuals who may have limited access to traditional mental health services. The intervention's ability to resonate across educational backgrounds, racial and ethnic identities, and socioeconomic strata highlights its potential as an equitable and scalable digital mental health tool.

The small effect estimates and largely nonsignificant differences should also be interpreted in the context of the study's early enrollment closure and resulting limited statistical power. However, the overall findings suggest that digital interventions such as W-PPMA hold promise for reducing postpartum psychological distress, particularly in populations with historically limited access to mental health care.

Comparison With Prior Work

Fitzpatrick et al [25] demonstrated that Woebot reduced anxiety and depression symptoms among young adults, and Prochaska et al [28,29] extended this work to substance use, reporting favorable usability and clinical outcomes. More recently, Suharwardy and Ramachandran [26,27] piloted Woebot in postpartum women, showing feasibility but in smaller, less diverse samples. Compared with these studies, our trial represents the largest randomized evaluation of Woebot in a postpartum cohort to date, and uniquely emphasized recruiting participants from underrepresented racial, ethnic, and socioeconomic groups. While the effect size for depressive symptoms was modest, it is consistent with early evaluations of DMHIs and underscores the importance of feasibility and acceptability outcomes as precursors to broader clinical impact. Our results extend the literature by demonstrating high engagement, satisfaction, and therapeutic alliance in a diverse postpartum population, highlighting W-PPMA's potential to address equity gaps in perinatal mental health care. It is also notable that guided digital interventions and telemedicine-delivered psychotherapy have generally shown stronger efficacy than unguided self-help programs [51,52]. Our modest effect sizes align with this broader pattern, while the

XSL•FO
RenderX

high feasibility and acceptability of W-PPMA underscore its potential as a scalable, lower-intensity option that complements rather than replaces clinician-delivered care.

Limitations

Although our sample included greater representation of racial and ethnic minority participants than many prior digital psychotherapy and postpartum intervention trials, it nevertheless remained majority White, which may constrain generalizability. This distribution is consistent with national surveillance data showing that most postpartum samples in the United States are majority White [7] and reflects a common challenge across perinatal mental health intervention trials. Selection bias is also possible, as participants were drawn from individuals already enrolled in the PowerMom digital research platform and willing to engage in an app-based trial, which may overrepresent those who are more digitally literate or motivated to participate in research. Our study was initially designed with a larger recruitment target to support efficacy analyses; however, early closure of enrollment resulted in an underpowered sample for detecting small to moderate effect sizes. Accordingly, efficacy findings should be interpreted as exploratory, while the primary study objectives of feasibility, acceptability, and satisfaction remain adequately addressed. Despite efforts to recruit underrepresented racial and ethnic groups, challenges in reaching some populations persisted. Future studies should consider additional strategies to ensure greater representation, such as leveraging community partnerships and multilingual recruitment materials.

Second, while this study demonstrated high engagement, the intervention's duration (8 wk) may have been insufficient to capture the full impact of W-PPMA on all outcomes, particularly for participants with more severe baseline symptoms of depression. Additionally, reliance on self-reported measures introduces the potential for response bias, and app engagement metrics may not fully capture the depth or nuance of participants' interactions with the intervention.

Third, an unexpected challenge was fraudulent attempts to obtain participation incentives (e-gift cards). The relatively high level of participant compensation may have contributed to fraudulent enrollment attempts. The platform's automated system was exploited by 580 fraudulent enrollments, leading to a rapid spike in participation in both the baseline study and the Woebot substudy. These accounts were detected and excluded before randomization, ensuring that the final analytic sample comprised only verified participants who met eligibility criteria. A small number of fraudulent accounts received e-gift card links before detection. We implemented anomaly detection measures, including monitoring the time taken to complete e-consent and baseline surveys and flagging irregular enrollment patterns (eg, duplicate IP addresses). These measures successfully curtailed fraudulent activity. Future studies should incorporate automated fraud detection tools from the outset to prevent disruptions and ensure data integrity.

Fourth, the lack of blinding and the use of a waitlist control group, rather than an active comparator, may have influenced participants' responses. While ethical considerations guided this choice, future research should explore the efficacy of W-PPMA against active comparators to better contextualize its effectiveness.

Finally, attrition and missing data were challenges, particularly among participants with higher baseline depressive symptoms. Although imputation methods and sensitivity analyses were used to address this, results should be interpreted with caution.

Future Directions

Future work should prioritize adequately powered randomized controlled trials with active comparators to rigorously assess clinical efficacy. Longer follow-up periods beyond 16 weeks will be essential to evaluate the durability of intervention effects and their potential role in relapse prevention. In parallel, implementation studies are needed to explore how W-PPMA can be integrated into postpartum care pathways, including obstetric, pediatric, and primary care settings. Real-world deployment of W-PPMA could involve integration within obstetric, pediatric, or primary care settings, where it may serve as a first-line or adjunctive support tool. As the intervention is automated, per-user delivery costs are likely to be substantially lower than clinician-delivered psychotherapy, although formal cost-effectiveness evaluations are needed. Finally, equity considerations remain central. Although our recruitment strategy successfully engaged historically underrepresented populations, additional strategies are needed to address barriers such as technology access, digital literacy, and bilingual delivery. Ensuring equitable reach and sustained engagement will be critical to maximizing the impact of DMHIs such as W-PPMA on postpartum mental health.

Conclusions

This research demonstrates W-PPMA's feasibility, acceptability, and potential as a scalable digital support tool for postpartum mental health in a diverse population. High user engagement and satisfaction underscore the intervention's usability, while exploratory findings suggest benefits for depressive symptoms and perceived stress. Importantly, W-PPMA's accessibility and cultural adaptability highlight its promise in addressing systemic barriers to postpartum mental health care, including stigma, cost, and provider shortages.

Beyond individual outcomes, these results contribute to the growing evidence base for DMHIs, extending prior work by demonstrating engagement and therapeutic alliance in a large, diverse postpartum cohort. Collectively, our findings position W-PPMA as a promising equitable solution to bridge persistent gaps in perinatal mental health support.

Acknowledgments

This study was made possible through the support of the PowerMom research platform and its consortium partners. We extend our gratitude to the community-based organizations that assisted in recruitment efforts, particularly those serving Black and

XSL•FO
RenderX

Hispanic/Latina populations. We also acknowledge the contributions of this study's participants, whose engagement and feedback have provided invaluable insights. From the Scripps Research team, we thank Shiri Warshawsky for her instrumental role in study operations and monitoring; Felipe Delgado, BS, for his contributions to custom development within MyDataHelps and preliminary data exports; and Giorgio Quer, PhD, and the Scripps Research data science team for setting up the initial coding necessary for this project. From the Woebot team, we would like to thank Stephanie Rapoport, MA, and Emily Durden, PhD, for their early contributions to drafting this study's protocol, Megan Flom, PhD, for quality control of the statistical analysis plan, and Stephanie Eaneff, MSP, for developing the code and extracting app usage data. Lastly, we thank the Institutional Review Board of the Scripps Research Translational Institute for their oversight and guidance in conducting this research.

Funding

This work received partial support from National Center for Advancing Translational Sciences (UM1TR004407) and from The Patrick J. McGovern Foundation.

Data Availability

The datasets generated and analyzed during the PowerMom study are not publicly available due to privacy and confidentiality restrictions. This study collected sensitive health and demographic data from participants, which are deidentified but remain protected under Institutional Review Board protocols. Researchers who wish to access the data for legitimate academic purposes can submit a formal request to the corresponding author. Requests will be evaluated on a case-by-case basis to ensure compliance with ethical guidelines and data use agreements. The code used for data analysis is available upon request from the corresponding author.

Authors' Contributions

TA and AR were principal investigators for this study and led this paper's writing, review, and revisions. Two statisticians (JW and JK), employees of Scripps Research with no relationship to Woebot, were responsible for the analyses. LA and LB managed project operations, reviewed this paper, and participated in drafting sections. ER and KB-M contributed to study design and provided high-level review and edits of this paper. AW contributed to the initial statistical analysis plan and paper review. GM contributed to statistical analysis and reviewed and edited the manuscript.

Conflicts of Interest

AR, AW, and MA, are employed by Woebot Health. LB is a former employee of Woebot Health.

Abstract

Background: Studies have indicated that maternal anxiety and depression during pregnancy can contribute to neurodevelopmental disorders and gut flora dysbiosis in children. However, it is unclear whether these factors increase the risk of autism spectrum disorder (ASD) with gastrointestinal (GI) symptoms in children.

Objective: This study aimed to analyze the relationship between maternal anxiety and depression during pregnancy and ASD with GI symptoms.

Methods: A total of 470 children with ASD and 486 children with typical development were enrolled in the study. The caregivers of all enrolled children completed questionnaires, including information on maternal mental health and GI symptoms.

Results: The percentage of maternal prenatal anxiety or depression was significantly higher in the ASD group than in the typical development group (P<.001). Children whose mothers experienced anxiety or depression during pregnancy had substantially higher risk of developing ASD than those whose mothers did not experience these conditions (unadjusted odds ratio [OR] 4.274, 95% CI 2.799-6.526; adjusted OR 3.897, 95% CI 2.481-6.119). For children with ASD, those whose mothers had prenatal anxiety or depression had a significantly higher risk of GI symptoms than those whose mothers did not have these conditions (unadjusted OR 1.883, 95% CI 1.209-2.934; adjusted OR 1.943, 95% CI 1.236-3.054).

Conclusions: Mothers who experience anxiety or depression during pregnancy may have a higher likelihood of their children developing ASD with GI symptoms.

KEYWORDS

autism spectrum disorder; gastrointestinal symptoms; comorbidity; risk factor; prenatal

Introduction

Autism spectrum disorder (ASD) is a neurodevelopmental disorder that has an early onset and significantly affects children's health. The common core symptoms of ASD are impaired social skills and communication and restricted or repetitive behaviors [1]. The etiology and pathogenesis of ASD are still not well understood. It is currently accepted that both genetic and environmental factors play key roles in the development of ASD [1]. Environmental conditions during early life, such as exposures during maternal pregnancy, may impact the neurodevelopment of children and increase the risk of ASD.

The manifestations of ASD are highly heterogeneous. In addition to the core symptoms, there are often comorbidities such as sleep disorders, attention-deficit/hyperactivity disorder, and gastrointestinal (GI) symptoms [2]. The etiology of ASD is also complex and cannot be explained by a single factor. Thus, certain causes may contribute to both core symptoms and comorbidities of ASD. GI symptoms are a common comorbidity of ASD, and quite a number of studies have shown that the prevalence of GI symptoms in children with ASD is much higher than in children with typical development [3]. As such, some factors may affect both early neurodevelopment and GI function, potentially leading to the development of ASD and GI symptoms.

The prenatal period is crucial for the neurodevelopment of children, and various environmental factors can greatly influence this development [4,5]. One important environmental factor is the mother's mental health status during pregnancy. Due to hormonal changes and other factors, some pregnant women who have no history of mental illness may develop psychological disorders, and thus, there is a relatively high prevalence of anxiety and depression during pregnancy [6,7]. Studies have demonstrated that maternal prenatal anxiety and

XSL•FO
RenderX

depression can affect the neurodevelopment of children and may be associated with neurodevelopmental disorders such as attention-deficit/hyperactivity disorder and cognitive disorders [8-10]. In addition, some studies have reported associations between maternal prenatal anxiety and depression and ASD in children. For instance, a large cohort study found that prenatal depression was associated with increased ASD-related traits in children [11]. Similarly, a meta-analysis reported an increased risk of ASD in children whose mothers experienced depressive disorders [12]. Another recent systematic review and meta-analysis demonstrated that maternal prenatal mood and anxiety disorders were associated with a significantly increased risk of ASD in children [13]. Pregnancy is also a critical period for the development of the enteric nervous system (ENS), and maternal anxiety and depression during this time have been found to alter the intestinal microbiota of children [14]. We speculate that maternal prenatal anxiety and depression may be linked to ASD and comorbid GI symptoms in children by simultaneously affecting the development of both the central nervous system and the ENS or by influencing children's gut microbiota and thereby affecting the development of both the brain and the gut via the gut-brain axis. Nevertheless, the relationship between prenatal anxiety and depression and GI symptoms in children is unclear, and the relationship between maternal anxiety and depression during pregnancy and ASD with GI symptoms has not been reported. Maternal anxiety and depression during pregnancy are mostly mild to moderate [15], but these symptoms may not be fully recognized and treated, partly because pharmacological interventions during pregnancy require particular caution and nonpharmacological interventions are not always readily available [16]. The purpose of this study was to analyze the relationship between mild and moderate maternal prenatal anxiety or depression and ASD in children, as well as the potential link between these conditions and ASD with GI symptoms.

Methods

Participants

A total of 470 children with ASD aged 2 to 7 years who visited the child psychobehavioral clinic of our hospital from July 2022 to June 2024 were recruited. The child psychobehavioral clinic is a specialized outpatient clinic within an affiliated hospital of a medical college primarily responsible for the diagnosis and treatment of developmental and behavioral disorders. Recruitment was conducted systematically: all children who visited the clinic with suspected or previously diagnosed ASD were screened for eligibility by the attending clinician. Then, a research coordinator contacted eligible families and explained the study purpose, procedures, and confidentiality protections. Families who agreed to participate were then scheduled for a comprehensive evaluation. The diagnosis of ASD was confirmed by 2 developmental-behavioral pediatricians based on the diagnostic criteria defined in the *Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition* [17], after a series of structured interviews and in combination with the results of the Childhood Autism Rating Scale (CARS) assessment. The CARS is a widely used standardized assessment scale for ASD symptoms, and individuals with a total CARS score of 30 or higher are considered to have ASD characteristics [18]. The exclusion criteria were history of developmental disabilities other than ASD or neurological disorders (children with ASD and co-occurring developmental disabilities were not excluded), severe physical or sensory impairment, no medical records of maternal mental health during pregnancy, history of maternal prepregnancy mental illness or paternal mental illness, physician-advised antidepressants or use of other medications (eg, antipsychotics, mood stabilizers, or anxiolytics) or substances (eg, alcohol, tobacco, or illicit drugs) during maternal pregnancy, and unwillingness to participate. Of the 522 initially screened children with ASD, 52 (10%) were excluded: 29 (5.6%) due to meeting the exclusion criteria and 23 (4.4%) due to parental refusal, resulting in a final sample size of 470 (90%). There were no missing data for the primary variables in the ASD group.

During the same period, 486 children with typical development were recruited from the child health clinic of the same hospital. They were frequency matched to the ASD group by sex and age. This clinic provides regular monitoring and guidance on the growth and development of children. Recruitment was conducted systematically: researchers approached families of children aged 2 to 7 years who attended the clinic for routine health checkups. After obtaining verbal consent, the researchers screened the children to ensure they met the inclusion criteria. Families who met the criteria were then invited to participate. The exclusion criteria were history of developmental disabilities or neurological disorders, severe physical or sensory impairment, no medical records of maternal mental health during pregnancy, history of maternal prepregnancy mental illness or paternal mental illness, physician-advised antidepressants or use of other medications (eg, antipsychotics, mood stabilizers, or anxiolytics) or substances (eg, alcohol, tobacco, or illicit drugs) during maternal pregnancy, and unwillingness to participate. Of the 532 children with typical development initially screened, 46 (8.6%) were excluded: 17 (3.2%) due to meeting the exclusion criteria and 29 (5.5%) due to parental refusal, resulting in a final sample size of 486 (91.4%). All enrolled participants with typical development completed the assessments, and there were no missing data for core variables in this group.

Ethical Considerations

The study protocol was approved by the ethics committee of the Affiliated Hospital of North Sichuan Medical College (2022ER268-1). Informed consent was obtained from the parents of all participants.

Questionnaires

Caregivers of all enrolled children, both those with ASD and those with typical development, completed questionnaires under the guidance of trained investigators, including questionnaires on general demographic information, maternal mental health during pregnancy, and GI symptoms. Prenatal anxiety or depression was determined based on 2 sources: scores on the Edinburgh Postnatal Depression Scale (cutoff of 10 or higher for depression) [19] and scores on the Self-Rating Anxiety Scale (cutoff of 50 or higher for anxiety) [20,21] completed during pregnancy, as well as medical records indicating clinical diagnoses of anxiety or depression by pregnancy care physicians.

XSL•FO
RenderX

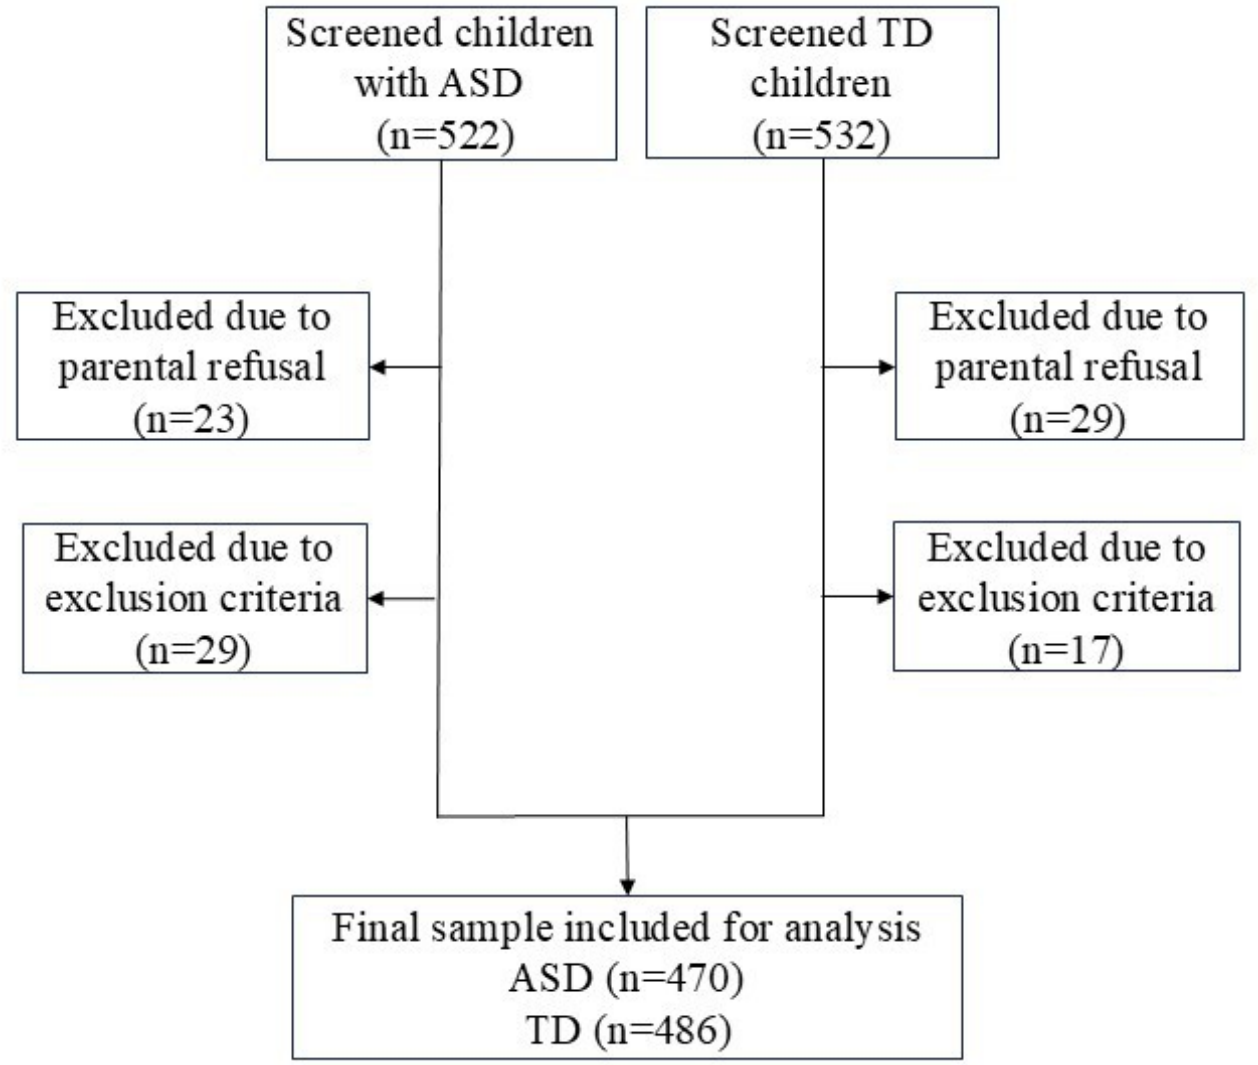
Only mothers who scored above the cutoff on the relevant scale and had a documented medical diagnosis were classified as having prenatal anxiety or depression. The GI symptom questions related to constipation, diarrhea, abdominal pain, flatulence, and nausea and vomiting were all based on the Questionnaire of Pediatric Gastrointestinal Symptoms–Rome IV (QPGS-IV), a validated tool for diagnosing functional GI disorders in infants and children [22]. The QPGS-IV defines a "GI symptom" as meeting specific frequency and duration thresholds (eg, diarrhea requires ≥4 loose stools per day for at least 1 month). As stool odor is not clearly defined in the QPGS-IV, it was defined as abnormal odor of the stool, such as rotten egg smell in this study [23]. A child was classified as screening positive for GI symptoms if at least 1 of the 6 GI symptoms was positive.

Covariates

The covariates we considered were age, sex, maternal educational level, paternal educational level, age of the mother at conception, mode of delivery, preterm birth, place of residence, and annual household income. Among these, maternal educational level, paternal educational level, mode of delivery, place of residence, and annual household income were significantly different between the ASD and typical development groups. Age, sex, and covariates that were significantly different between the ASD and typical development groups were all included in the logistic regression model.

Statistical Analyses

The data analysis was conducted using the SPSS statistical software (version 25; IBM Corp). Before analysis, the distribution of each dataset was tested for normality using the Kolmogorov-Smirnov goodness-of-fit test. The nonnormally distributed continuous variables were described using medians and IQRs, and differences between groups were assessed using the Mann-Whitney *U* test. Categorical variables were described as frequencies and percentages, and differences between groups were assessed using the chi-square test. Binary logistic regression was used to evaluate the relationship between prenatal anxiety or depression and the risk of ASD in children, as well as the link between prenatal anxiety or depression and the risk of GI symptoms in children with ASD.



Results

Characteristics of the Participants in the Typical Development and ASD Groups

The present study included 470 children with ASD (388 male and 82 female) and 486 children with typical development (388 male and 98 female; Figure 1). The median age of the ASD group was 4.0 (IQR 3.2-4.9) years, and that of the typical development group was 4.3 (IQR 3.1-5.3) years. There were no significant differences in sex ratio or age distribution between the 2 groups. As shown in Table 1, there were significant differences between the 2 groups in terms of both the maternal and paternal educational levels ($P<.001$), with increased proportions of both mothers and fathers with lower educational levels and decreased proportions of those with higher educational levels in the ASD group compared to the typical development group. There were no significant differences in the age of mothers at conception ($P=.70$) or the proportion of preterm births ($P=.40$) between the 2 groups. However, the proportion of vaginal delivery was significantly lower, and the proportion that lived in urban areas was also significantly lower in the ASD group than in the typical development group ($P<.01$). The annual household income was significantly different between the 2 groups ($P<.001$). In the ASD group, the proportion of those with an income below CN¥ 50,000 (CN¥ 1=US $0.15 as of October 15, 2026) was higher, while that of those with an income above CN¥ 100,000 was significantly lower.

[a]*z* statistic.

[b]chi-square statistic.

[c]GI: gastrointestinal.

In the ASD group, 22.6% (106/470) of the individuals had maternal prenatal anxiety or depression, while only 6.4% (31/486) in the typical development group did. The percentage of maternal prenatal anxiety or depression was significantly higher in the ASD group than in the typical development group (*P*<.001).

XSL•FO
RenderX

In addition, 50.2% (236/470) of the children in the ASD group had GI symptoms compared with 26.5% (129/486) in the typical development group. The GI symptoms were significantly higher in the ASD group than in the typical development group (*P*<.001).

Associations Between Maternal Prenatal Anxiety or Depression and the Risk of ASD in Children

To examine the potential link between maternal prenatal anxiety or depression and ASD in children, we conducted logistic regression analysis. The results, shown in Table 2, indicate that in univariate logistic regression, prenatal anxiety or depression (odds ratio [OR] 4.274, 95% CI 2.799-6.526), lower maternal educational level (secondary school: OR 2.987, 95% CI 2.255-3.957; primary school or lower: OR 16.813, 95% CI 2.157-131.049), lower paternal educational level (secondary school: OR 2.355, 95% CI 1.779-3.118; primary school or lower: OR 16.719, 95% CI 2.161-129.360), nonvaginal delivery (OR 1.483, 95% CI 1.149-1.913), and nonurban residence (OR 3.560, 95% CI 2.400-5.281) were all associated with an increased risk of ASD, while higher household income (CN¥ 50,000-100,000: OR 0.676, 95% CI 0.485-0.941; >CN¥ 100,000: OR 0.179, 95% CI 0.129-0.248) was linked to a reduced risk of ASD. To assess independent effects, we included all significant variables along with age and sex into a multivariable logistic regression model. The results showed that maternal prenatal anxiety or depression remained a significant risk factor for ASD (adjusted OR 3.897, 95% CI 2.481-6.119). Among the other variables, maternal educational level (secondary school vs college or higher: adjusted OR 1.865, 95% CI 1.232-2.823), delivery mode (adjusted OR 1.387, 95% CI 1.042-1.845), residence (adjusted OR 2.076, 95% CI 1.326-3.252), and household income (>CN¥ 100,000 vs <CN¥ 50,000: adjusted OR 0.252, 95% CI 0.176-0.362) also remained significant but with smaller effect sizes than prenatal anxiety or depression. Paternal educational level was no longer significant (*P*>.05).

Table . Univariate and multivariate logistic regression analysis of factors potentially associated with autism spectrum disorder.

Comparison of GI Symptoms and Their Association With Maternal Prenatal Anxiety or Depression in Children With ASD

We compared the GI symptoms in children with ASD whose mothers had and did not have prenatal anxiety and depression. As shown in Table 3, a total of 62.3% (66/106) of children with ASD whose mothers had prenatal anxiety or depression exhibited at least one GI symptom, while 46.7% (170/364) of children with ASD whose mothers did not have prenatal anxiety and depression exhibited GI symptoms. Our analysis revealed that children with ASD whose mothers had prenatal anxiety or depression had a significantly higher proportion of GI symptoms than those whose mothers did not have prenatal anxiety and depression (P<.01). Specifically, the rates of constipation and abdominal pain were significantly higher in children with ASD whose mothers had anxiety or depression during pregnancy (P<.01). However, there was no significant difference in the prevalence of diarrhea, nausea and vomiting, flatulence, and stool odor between the 2 groups (P>.05).

Table . Comparison of gastrointestinal (GI) symptoms between children with autism spectrum disorder (ASD) whose mothers had and did not have prenatal anxiety and depression.

Symptoms	ASD without prenatal anxiety or depression (n=364), n (%)	ASD with prenatal anxiety or depression (n=106), n (%)	Chi-square (*df*)	*P* value
Constipation	105 (28.8)	47 (44.3)	9.0 (1)	.003
Diarrhea	25 (6.9)	10 (9.4)	0.8 (1)	.38
Abdominal pain	43 (11.8)	25 (23.6)	9.2 (1)	.002
Nausea or vomit	24 (6.6)	9 (8.5)	0.5 (1)	.50
Flatulence	18 (4.9)	10 (9.4)	3.0 (1)	.09
Stool odor	36 (9.9)	14 (13.2)	1.0 (1)	.33
Total GI symptoms	170 (46.7)	66 (62.3)	8.0 (1)	.005

We further assessed the relationship between maternal prenatal anxiety or depression and the risk of GI symptoms in children with ASD. Our findings, as shown in Table 4, indicate that children with ASD whose mothers experienced anxiety or depression during pregnancy had a significantly higher risk of total GI symptoms than children whose mothers did not have these conditions (OR 1.883, 95% CI 1.209-2.934). This trend remained consistent even after adjusting for age, sex, maternal educational level, paternal educational level, mode of delivery, place of residence, and annual household income (adjusted OR 1.943, 95% CI 1.236-3.054). Specifically, the risk of constipation and abdominal pain was significantly higher in children with ASD whose mothers had prenatal anxiety or depression than in those whose mothers did not have these conditions (OR 1.965, 95% CI 1.259-3.067 and OR 2.304, 95% CI 1.329-3.993, respectively). These results were still evident after adjusting for covariates (adjusted OR 2.083, 95% CI 1.315-3.299 and adjusted OR 2.302, 95% CI 1.305-4.062, respectively). However, there was no significant increase in the risk of diarrhea, nausea and vomiting, flatulence, or stool odor in children with ASD whose mothers had prenatal anxiety or depression compared to those whose mothers did not have these conditions (P>.05).

Table . Association between maternal prenatal anxiety or depression and the risk of gastrointestinal (GI) symptoms in children with autism spectrum disorder (ASD).

GI comorbidities in ASD	Unadjusted		Adjusted[a]	
	OR[b] (95% CI)	*P* value	OR (95% CI)	*P* value
Constipation	1.965 (1.259-3.067)	.003	2.083 (1.315-3.299)	.002
Diarrhea	1.412 (0.656-3.043)	.38	1.530 (0.692-3.385)	.29
Abdominal pain	2.304 (1.329-3.993)	.003	2.302 (1.305-4.062)	.004
Nausea and vomiting	1.314 (0.591-2.921)	.50	1.335 (0.581-3.067)	.50
Flatulence	2.002 (0.895-4.480)	.09	2.154 (0.922-5.031)	.08
Stool odor	1.386 (0.717-2.680)	.33	1.272 (0.646-2.505)	.49
Total GI symptoms	1.883 (1.209-2.934)	.005	1.943 (1.236-3.054)	.004

Discussion

Principal Findings

The clinical manifestation of ASD is highly heterogeneous, often with comorbidities such as GI symptoms in addition to the core symptoms [24]. Certain causes may lead to developmental abnormalities in both the brain and GI tract, resulting in ASD with GI symptoms. In this study, we investigated the impact of maternal mental health, specifically anxiety or depression during pregnancy, on the likelihood of ASD and GI symptoms in children.

In our study, we found that the prevalence of maternal prenatal anxiety or depression was 6.4% (31/486) in children with typical development and 22.6% (106/470) in children with ASD. This is a relatively high prevalence and is consistent with findings from other studies [9,25]. Our study also revealed a significant difference in the prevalence of maternal prenatal anxiety or depression between children with ASD and children with typical development, suggesting a potential link between prenatal mental health and the development of ASD in children. We used logistic regression models to further examine this association. In the univariate analysis, factors including prenatal anxiety or depression, lower maternal and paternal educational level, nonvaginal delivery, nonurban residence, and lower household income were all significantly associated with increased risk of ASD. To assess the independent effect of prenatal anxiety or depression, we included all these variables along with age and sex in the multivariable logistic regression model. The results showed that maternal prenatal anxiety or depression remained a significant independent risk factor for ASD (adjusted OR 3.897, 95% CI 2.481-6.119). Although some other variables also retained significance, their effect sizes were smaller than that of prenatal anxiety or depression. These findings suggest that maternal prenatal anxiety or depression may independently increase the risk of ASD in children. This is consistent with previous cohort studies linking maternal anxiety or depression before birth to ASD or ASD-related traits [11,26,27] and with systematic reviews and meta-analyses reporting increased ASD risk among children of mothers with affective, depressive, or anxiety disorders [12,13]. Although the precise mechanisms remain to be clarified, both animal and human studies have demonstrated that maternal prenatal anxiety and depression may be associated with neurodevelopmental disorders [28]. As such, addressing and managing maternal prenatal anxiety and depression may be crucial for reducing the prevalence of neurodevelopmental disorders, including certain forms of ASD, in children.

GI symptoms are a common comorbidity in children with ASD [3]. In the present study, we found that 50.2% (236/470) of children with ASD had GI symptoms, which was significantly higher than the proportion of children with typical development with GI symptoms. Additionally, we compared the prevalence of GI symptoms in children with ASD whose mothers had and did not have prenatal anxiety and depression. The results showed that for children with ASD whose mothers had prenatal anxiety or depression, the prevalence of total GI symptoms was 62.3% (66/106), which was significantly higher than that of children with ASD whose mothers did not have prenatal anxiety and depression (170/364, 46.7%). Among the GI symptoms, the prevalence of constipation and abdominal pain was significantly higher in children with ASD whose mothers had prenatal anxiety or depression than in children with ASD whose mothers did not have prenatal anxiety and depression. This suggests a potential link between maternal anxiety and depression during pregnancy and GI symptoms in children with ASD. Furthermore, we used logistic regression models to analyze the relationship between maternal prenatal anxiety or depression and GI symptoms in children with ASD. The results suggested that maternal prenatal anxiety and depression might be risk factors for GI symptoms in children with ASD, with an increased risk of constipation, abdominal pain, and total GI symptoms. This trend remained consistent even after adjusting for potential confounding factors. It has been reported that there is a correlation between maternal depressive symptoms and infant gastroesophageal reflux disease and constipation [29]. However, to our knowledge, no other research has explored the link between maternal anxiety and depression during pregnancy and GI symptoms in children with ASD.

The mechanisms underlying the association between maternal prenatal anxiety and depression and ASD with GI symptoms in children are unknown. Depression and anxiety are highly comorbid with GI abnormalities as well as microbiome dysbiosis [30,31]. In the case of maternal depression during pregnancy, they can also have a significant impact on both the mother's and the child's gut microbiome [32]. A study conducted by Galley et al [14] also supports the idea that maternal prenatal anxiety and depression can affect the gut microbiome of children. Additionally, prenatal stress has been found to affect placental cytokines and neurotrophins [33]. Moreover, an animal study has suggested that maternal microbiome can modulate fetal neurodevelopment [34]. In addition, abnormalities in the development of the brain and ENS can contribute to the development of ASD and GI symptoms [35]. Thus, we speculate that maternal prenatal anxiety and depression may affect the development of children's brains and GI tracts through abnormalities in maternal microbiota as well as abnormalities in placental function, or it may directly affect children's gut microbiota and further influence brain development through the gut-brain axis, which may increase the risk of ASD and GI symptoms in children. However, the specific mechanisms need to be further explored in animal experiments.

Limitations

This study has several limitations. First, it was a cross-sectional study, which does not allow for causal inferences to be made about the relationship between prenatal anxiety and depression and ASD with GI symptoms. In addition, some of the questionnaire data, including general demographic information and certain maternal mental health information, were collected retrospectively at enrollment when the children were aged 2 to 7 years and, thus, may be subject to retrospective recall bias. Second, there is no standardized and validated method for assessing GI symptoms in children with ASD. In this study, GI symptoms were judged based on the caregivers' answers to questions based on the QPGS-IV, and children with ASD usually have communication problems, so there may be bias in

XSL•FO
RenderX

evaluating GI symptoms. Third, although we adjusted for major confounding factors, our analysis may still have residual unmeasured confounding such as maternal fever, obesity, and diabetes, which were not included in the analysis and could influence the observed associations. Finally, as the ASD group was recruited from a specialized tertiary behavioral clinic while the typical development group was drawn from a routine well-child health clinic, there may be potential selection and referral biases due to differences in referral pathways and clinic attendance.

Conclusions

Our study found that a higher proportion of children with ASD had mothers with prenatal anxiety and depression compared to children with typical development. Children with ASD whose mothers experienced anxiety or depression during pregnancy had significantly higher rates of GI symptoms than children with ASD whose mothers did not experience anxiety and depression during pregnancy. Our logistic regression models suggest that maternal prenatal anxiety and depression may increase the risk of ASD and GI symptoms in children. These findings highlight the importance of mental health during pregnancy and that even mild and moderate anxiety and depression may increase the risk of ASD and GI symptoms in children, so they need to be actively prevented and treated.

Abstract

Background: Postpartum maternal mental health (MMH) symptoms, including depression, anxiety, and childbirth-related post-traumatic stress disorder, are known to influence infant sleep trajectories. While previous research has examined their individual and combined associations, the predictive utility of these MMH symptoms for the early identification of infant sleep problems through machine learning (ML) remains understudied.

Objective: This study aimed to examine whether postpartum MMH measures can predict infant sleep outcomes during the first year of life. The analysis focused on 2 clinically relevant sleep indicators: (1) nocturnal sleep duration and (2) night awakening frequency.

Methods: A total of 409 mother-infant dyads were included in the study. Predictor variables comprised postpartum MMH symptoms assessed between 3 and 12 months postpartum, along with sociodemographic characteristics of mothers and infants. MMH symptoms were measured using 3 validated instruments: the Edinburgh Postnatal Depression Scale, the Hospital Anxiety and Depression Scale, and the City Birth Trauma Scale. Infant sleep outcomes were assessed using the Brief Infant Sleep Questionnaire. Six supervised ML algorithms were evaluated: logistic regression, random forest, support vector classifier, extreme gradient boosting, Light Gradient Boosting Machine, and multilayer perceptron. Post hoc feature importance analyses were conducted to identify the most influential predictors associated with each infant sleep outcome.

Results: All models demonstrated high predictive performance. The best model achieved a precision-recall area under the curve of 0.92, F_1-score of 0.84, and accuracy of 0.88 for predicting short nocturnal sleep duration. For frequent night awakenings, the top precision-recall area under the curve was 0.91, with an F_1-score of 0.78 and accuracy of 0.85. Key predictors included maternal age and total scores from the Edinburgh Postnatal Depression Scale, Hospital Anxiety and Depression–Anxiety subscale, and City Birth Trauma Scale, with individual symptom items offering additional discriminative value.

Conclusions: ML models can accurately predict which infants are at risk for suboptimal sleep based on MMH measures, enabling personalized, responsive, and developmentally informed postpartum care that promotes long-term maternal and infant well-being.

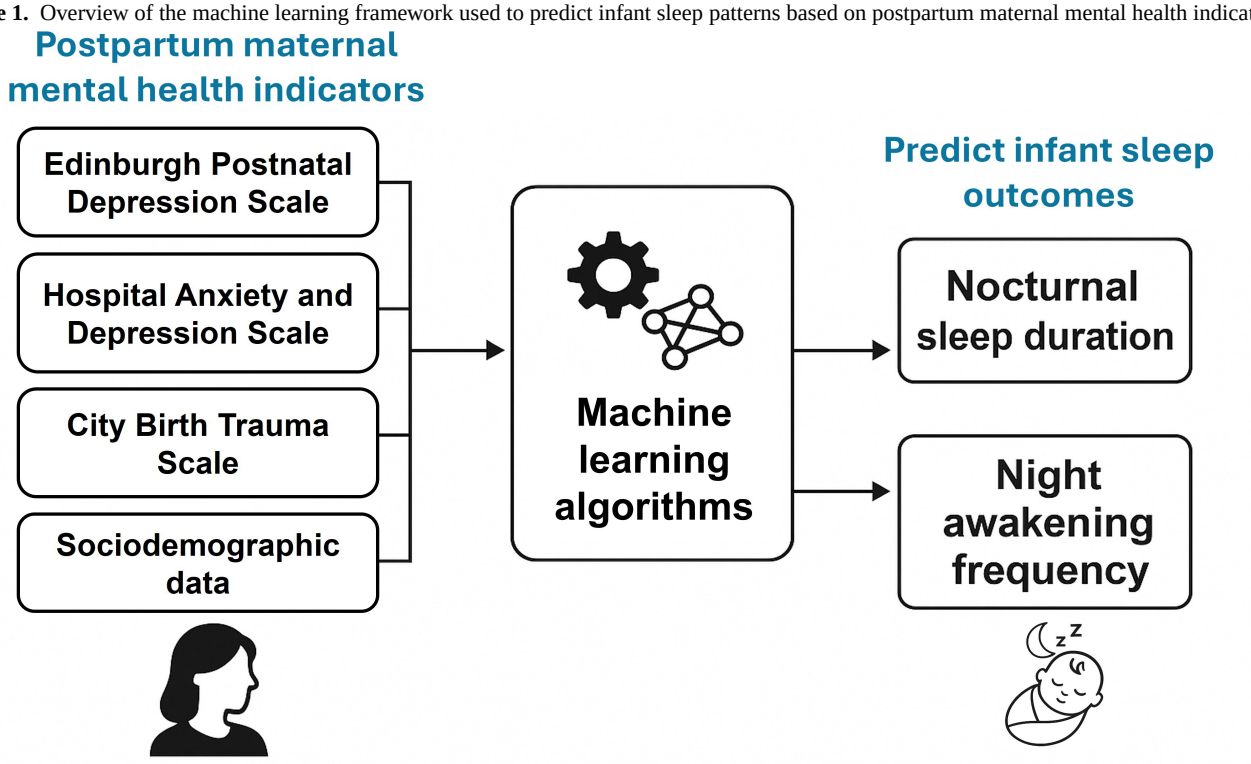
Introduction

Infant sleep plays a foundational role in early neurodevelopment, with significant implications for cognitive functioning, emotional regulation, physical growth, and long-term health outcomes [1-3]. During the first year postpartum, infant sleep patterns are highly dynamic and marked by individual variability in both nocturnal sleep duration and the frequency of night awakenings. Insufficient or fragmented sleep during this critical period has been associated with impaired memory consolidation, behavioral dysregulation, and suboptimal emotional development [4,5].

A growing body of research [6-12] has demonstrated that maternal mental health (MMH) symptoms during the postpartum period, including depression [13,14], anxiety [8,15], and childbirth-related post-traumatic stress disorder (CB-PTSD) [16,17], are associated with alterations in infant sleep architecture. However, the underlying mechanisms through which these maternal conditions influence infant sleep remain

XSL•FO
RenderX



poorly understood [18]. Furthermore, most prior studies have examined these symptoms in isolation or as covariates, without evaluating their collective predictive value using integrative modeling approaches.

In parallel, machine learning (ML) approaches offer a powerful alternative to traditional regression techniques. Beyond simply reproducing associations already established using regression or structural equation models, ML offers added value by flexibly capturing nonlinear relationships and higher-order interactions among MMH symptoms and covariates. In this context, ML models can benchmark a range of algorithms on predictive performance, support individual-level risk stratification, and highlight symptom patterns that are most informative for early identification of infants at risk of sleep disturbance. In turn, this can refine existing theoretical models and guide more targeted, data-driven clinical decision support.

Recent studies have demonstrated the utility of ML in various infant sleep and postpartum mental health applications [19]. For example, Wang et al [20] developed an automated sleep-stage classifier using heart rate and respiratory rate data to predict white matter development in preterm infants. Similarly, Werth et al [21] designed a deep learning–based system for sleep-stage classification in preterm infants using electrocardiogram (ECG) signals. Additionally, the Sleep Well Baby project introduced a real-time sleep-wake state prediction algorithm based on physiological signals, facilitating improved monitoring in neonatal intensive care units [22]. In another study, Chang et al [23] utilized a multimodal wearable device to collect audio, ECG, and motion data, employing transformer-based neural networks to classify infant sleep/wake states with high accuracy. Furthermore, Huang et al [24] applied ML models to classify and identify infant sleep positions. However, existing ML-based studies have mostly focused on characterizing infant sleep problems using demographic, behavioral, or sensor-derived features, without explicitly leveraging MMH symptoms as primary predictors. To date, no study has examined whether postpartum MMH symptoms can be used, in conjunction with ML methods, to predict infant sleep patterns during the first year of life.

The present study addresses this gap by leveraging ML methods to predict infant sleep trajectories across the first year postpartum based on MMH symptoms and sociodemographic characteristics of mothers and infants. Specifically, we aimed to evaluate the performance of six supervised ML models in predicting two clinically relevant sleep outcomes: nocturnal sleep duration and the frequency of night awakenings (Figure 1). In addition, feature importance analyses were conducted to identify key MMH predictors associated with each outcome.

Figure 1. Overview of the machine learning framework used to predict infant sleep patterns based on postpartum maternal mental health indicators.

We hypothesized that postpartum MMH symptom measures, in combination with basic maternal-infant characteristics, would enable supervised ML models to accurately predict infant sleep outcomes. To operationalize this hypothesis, we addressed the following research questions: (1) Can MMH indicators and sociodemographic characteristics accurately predict infant sleep outcomes (ie, nocturnal sleep duration and night awakening frequency) during the first year postpartum using ML models? and (2) Which MMH features are most predictive of infant sleep outcomes across the first year postpartum? By characterizing the predictive utility of MMH symptoms and elucidating the most influential features, this study seeks to inform early screening and intervention strategies to optimize both MMH and infant developmental well-being.

Methods

Study Population and Data Sources

This study utilized a publicly available dataset [11] comprising 410 mother-infant dyads, collected via an online cross-sectional survey conducted between June and September 2020 at a university hospital in Switzerland. Eligible participants were birth mothers aged 18 years or older with infants between 3 and 12 months of age at the time of data collection and with no reported major neonatal complications.

The dataset included measures of MMH symptoms, infant sleep outcomes, and sociodemographic characteristics of both mothers and infants. A detailed description of the input features used in the analysis is provided in Multimedia Appendix 1. One mother-infant dyad was excluded due to missing information on nocturnal sleep duration, resulting in a final sample of 409 dyads.

Data Elements

MMH Measures

MMH symptoms were assessed using 3 validated self-report instruments: the Edinburgh Postnatal Depression Scale (EPDS), the Hospital Anxiety and Depression Scale-Anxiety subscale (HADS-A), and the City Birth Trauma Scale (CBTS). These measures were selected to comprehensively capture postpartum symptoms of depression, anxiety, and CB-PTSD, respectively.

The EPDS is a 10-item screening tool designed to detect symptoms of postnatal depression in women [25]. It focuses on emotional and cognitive symptoms experienced during the preceding week, excluding somatic complaints that may overlap with normal postpartum changes. Each item is scored on a 4-point Likert scale, and total scores ranging from 0 to 40, with higher scores indicating greater symptom severity.

The HADS-A is the anxiety subscale of the Hospital Anxiety and Depression Scale [26]. It consists of 7 items that assess the frequency and severity of anxiety symptoms experienced during the preceding week. Responses are rated on a 4-point scale, yielding a total score ranging from 0 to 21, where higher scores reflect more severe anxiety symptomatology.

The CBTS is a 29-item instrument [27] specifically developed to assess CB-PTSD symptoms based on the Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition (*DSM-5*). The scale is divided into 2 subscales: the birth-related symptoms subscale, which assesses intrusion and avoidance symptoms as well as a subset of negative mood items, and the general symptoms subscale, which captures remaining negative cognition and hyperarousal symptoms. The total score for the *DSM-5*–based items ranges from 0 to 60, with higher scores indicating greater severity of CB-PTSD symptoms. Together, these 3 instruments provided a multidimensional assessment of postpartum MMH, enabling the identification of symptom patterns relevant to infant sleep outcomes.

Infant Sleep Measures

Infant sleep was assessed using the Brief Infant Sleep Questionnaire (BISQ), a widely used and validated parent-report instrument designed to evaluate sleep behavior in infants and toddlers [28]. Mothers were asked to report on their infant's sleep patterns over the preceding week, including total nocturnal sleep duration (between 7:00 PM and 7:00 AM), frequency of night awakenings, and method of falling asleep. For the purposes of this study, 2 primary sleep outcomes were derived and categorized as binary variables: nocturnal sleep duration and night awakenings, both of which serve as indicators of infant sleep quality.

Nocturnal sleep duration was classified as either normal (coded as 0) or insufficient (coded as 1). Infants were categorized as having normal nocturnal sleep if their reported sleep duration was ≥9 hours, for all infant age groups. Infants who slept for less than 9 hours per night were classified as having insufficient nocturnal sleep duration. This threshold aligns with prior research and pediatric sleep guidelines that recommend a minimum of 9 hours of nighttime sleep for infants aged 3 to 12 months [29] .

Night awakenings were categorized based on age-specific thresholds. For infants aged 3 to 6 months, normal was defined as ≤3 awakenings per night. For infants aged 6 to 9 and 9 to 12 months, normal was defined as ≤2 awakenings per night. Infants exceeding these thresholds were classified as having frequent night awakenings, consistent with existing sleep research indicating that night waking typically decreases with age as self-regulation improves [30].

Nocturnal sleep duration and night-awakening frequency were modeled as separate primary outcomes because they capture distinct dimensions of infant sleep—quantity (duration) versus continuity (awakenings)—that may have partially different determinants (eg, circadian scheduling/feeding patterns versus arousal regulation) and lead to different clinical actions. Their measurement properties also differ (duration: continuous; awakenings: count/ordinal), warranting distinct modeling approaches and metrics. Analyzing them separately preserves interpretability of feature effects and supports symptom-targeted guidance. Although the 2 domains can co-occur, our predictive focus is outcome-specific.

Data Preprocessing

Preprocessing steps included computing total scores for the maternal mental health instruments (EPDS, HADS-A, and CBTS) according to their manuals and recoding response options for consistency across instruments. For each instrument, both the individual item responses and the derived total scores were retained as candidate predictors, allowing the models to leverage overall symptom burden as well as more fine-grained symptom patterns (eg, specific anxiety, depression, or trauma-related items). Missing values were imputed (numerical features: mean; categorical features: mode). Numerical features were then standardized (z score), and categorical features were one-hot encoded to ensure consistent transformations during model training and evaluation. This procedure yielded a clean, model-ready feature matrix for all classifiers. Because the study's primary aim was to evaluate predictive performance rather than coefficient-level inference, we did not perform formal multicollinearity diagnostics (eg, VIF). Including both total scores and item-level responses intentionally introduces

XSL•FO
RenderX

some correlation among predictors; however, many of the algorithms employed (eg, tree-based learners and regularized linear models) are designed to handle correlated and partially redundant features by down-weighting or shrinking less informative variables. Potential overfitting from the expanded feature space was further mitigated through cross-validated hyperparameter tuning and evaluation on a held-out test set.

ML Models

Six ML algorithms were employed to predict infant sleep outcomes based on MMH measures and demographic features. These models were selected to represent a diverse range of linear and nonlinear classifiers, including both ensemble and neural network-based approaches.

- Logistic regression: A linear classification algorithm that estimates the probability of a binary outcome based on a weighted combination of input features.
- Random forest: An ensemble learning method that constructs multiple decision trees during training and outputs the class that is the mode of the predictions of the individual trees.
- Support vector classifier: A kernel-based method that identifies the optimal hyperplane separating classes in a high-dimensional feature space.
- extreme gradient boosting (XGBoost): A gradient-boosted decision tree algorithm known for its scalability and performance. It builds an ensemble of weak learners sequentially, optimizing residual errors from prior iterations.
- Light gradient boosting machine (LightGBM): A gradient boosting framework that uses histogram-based learning and leaf-wise tree growth.
- Multilayer perceptron (MLP): A feedforward artificial neural network composed of fully connected layers. It captures complex, nonlinear interactions among features and is trained using backpropagation.

Each questionnaire item and each derived total score was treated as a separate candidate predictor. Modern supervised ML algorithms (eg, tree-based ensembles and regularized models) are generally robust to moderately correlated predictors and can down-weight or ignore redundant features during training, so including both item-level and total-score features does not compromise model learning or model behavior; instead, it allows the algorithm to "decide" whether predictive signal is better captured at the composite-score or item level.

Models Training and Evaluation Strategy

Both outcome variables exhibited class imbalance. For nocturnal sleep duration, 359/409 infants (87.8%) were classified as normal (class 0) and 50/409 (12.2%) as insufficient (class 1). For night awakenings, 346/409 infants (84.6%) were classified as normal (class 0) and 63/409 (15.4%) as elevated (class 1). To address this, we applied 2 strategies. First, we evaluated each model using 4 sampling methods: no sampling, random upsampling, random downsampling, and synthetic minority oversampling technique (SMOTE). This allowed us to assess the impact of different data distributions on model performance. Second, we used evaluation metrics suited for imbalanced data. In addition to accuracy, we computed the precision-recall area under the curve (PR-AUC), which focuses on the minority class and is not influenced by the number of true negatives. We also reported the F_1-score, the harmonic mean of precision and recall, which balances false positives and false negatives. Together, these strategies ensured reliable evaluation of model performance in the context of class imbalance.

All analyses were conducted at the level of the mother-infant dyad. The dataset (N=409 dyads) was randomly split into training (327/409, 80%) and test (82/409, 20%) sets, using stratified sampling to preserve the proportion of infants with nocturnal sleep disturbance and frequent night awakenings in both partitions. All model development (including hyperparameter tuning and internal validation) was performed exclusively on the training set. All analyses were implemented in Python and performed on a high-performance computing node equipped with an NVIDIA A100 GPU (80 GB memory).

To quantify the variability and robustness of model performance, we additionally performed stratified 5-fold cross-validation within the training set for each model-sampling combination. For every fold, we computed PR-AUC, accuracy, and F_1-score and summarized their distribution across folds. Final performance for each model was then evaluated on the held-out test set.

Models Explainability

To characterize which MMH and covariate features contributed most to predictions, we first computed model-based feature importance for the best-performing model for each outcome (as determined by PR-AUC on the held-out test set), using the model's native importance measure. To further enhance interpretability, we then performed a post hoc explainability analysis using Shapley additive explanations (SHAP). For each outcome, we computed SHAP values for all input features. SHAP values quantify the marginal contribution of each feature to the predicted probability of the positive (sleep disturbance) class for individual mother-infant dyads. We summarized global importance by the mean absolute SHAP value across participants and visualized the distribution of feature effects using SHAP summary (beeswarm) plots, as complementary views to the main feature-importance analyses.

Ethical Considerations

This study did not involve the collection or generation of original human subject data. Instead, it utilized publicly available, deidentified data from a licensed source. As such, institutional review board approval and informed consent were not required.

Results

Participant Characteristics

A total of 409 mother-infant dyads were included. Participant characteristics and summary measures are shown in Table 1. The mean maternal age was 30.20 (SD 4.36) years. Nearly half held a university degree (192/409, 46.9%); 388 out of 409 (94.9%) were in a couple relationship. Overall, 51.6% (211/409) of the infants were female and 48.4% (198/409) were male. The mean gestational age at birth was 39.11 (SD 1.90) weeks. At

XSL•FO
RenderX

assessment, infants were distributed as follows: 147/409 (35.9%) were aged 3 to <6 months, 133/409 (32.5%) aged 6 to <9 months, and 129/409 (31.5%) aged 9 to <12 months. MMH means were 9.06 (SD 6.76) on the EPDS, 7.85 (SD 4.26) on the HADS-A, and 13.15 (SD 10.81) on the CBTS.

Table . Sample characteristics and key measures (N=409).

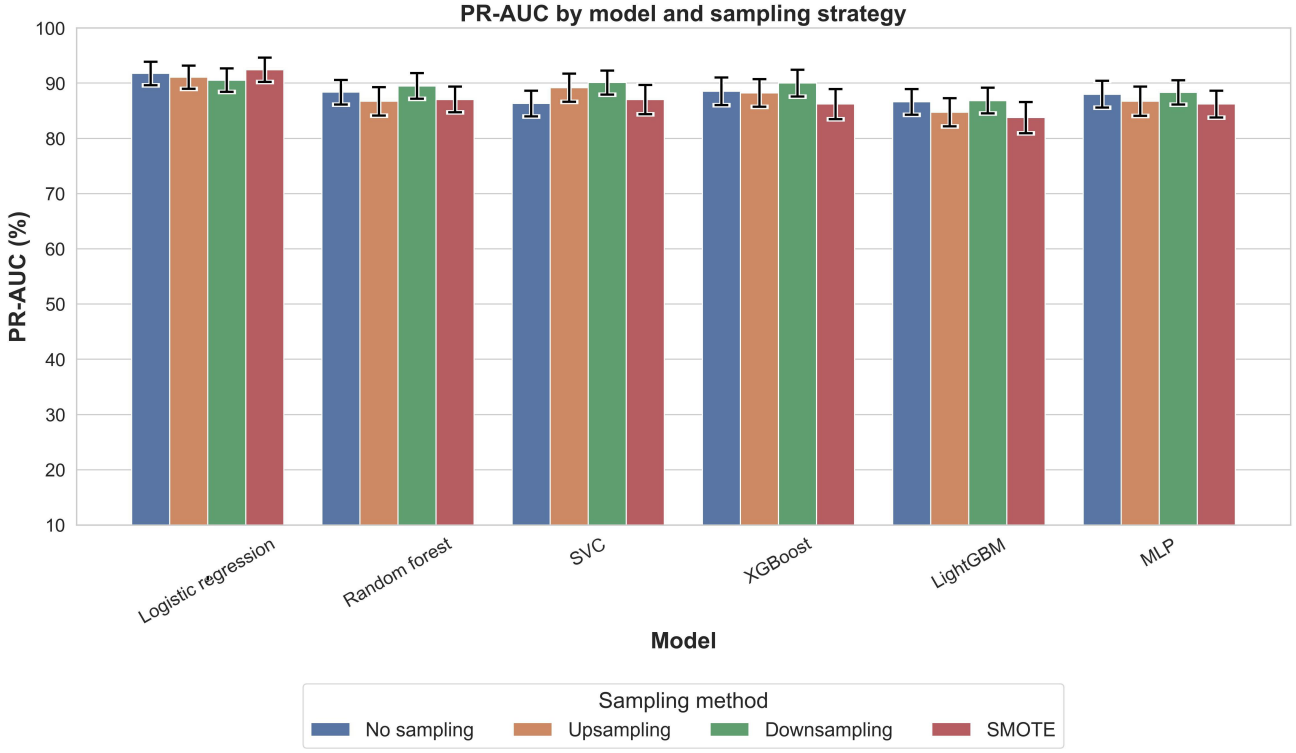
Prediction of Nocturnal Sleep Duration

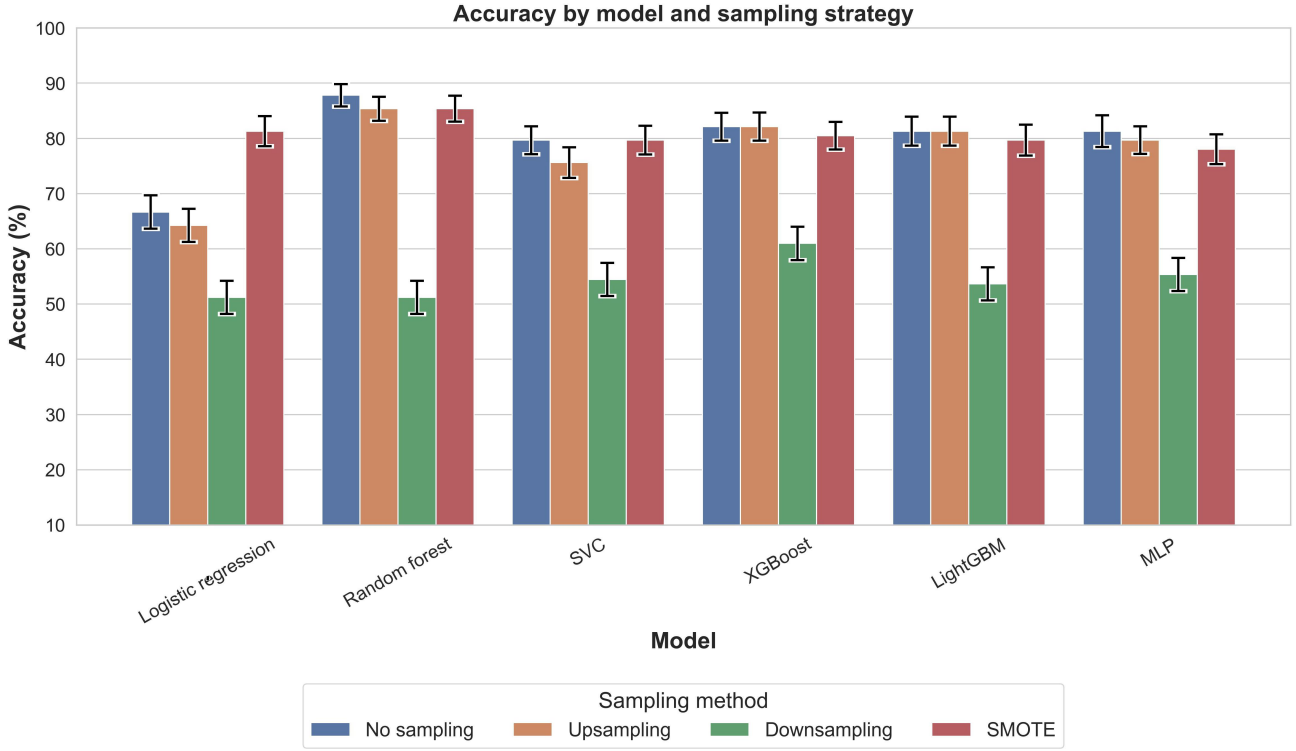
Models Performance

Figure 2 presents PR-AUC values for each model across 4 sampling strategies. All configurations achieved PR-AUC values above 0.88, with XGBoost with SMOTE highest (0.931), followed by logistic regression with SMOTE (0.924). Accuracy (Figure 3) showed greater variability, with XGBoost without sampling highest (0.886), followed by random forest without sampling or with upsampling (0.878). F_1-scores (Figure 4) mirrored these trends: XGBoost without sampling achieved the highest F_1 (0.840), followed by random forest (0.821) and support vector classifier/MLP (0.820) with either no sampling or SMOTE.

XSL•FO
RenderX

Figure 2. Comparison of the precision-recall area under the curve (PR-AUC) across models and sampling methods for outcome nocturnal sleep duration. PR-AUC quantifies how well a model can distinguish positive cases (infants with insufficient nocturnal sleep duration) from negative ones across various thresholds, especially under class imbalance conditions. LightGBM: light gradient boosting machine; MLP: multilayer perceptron; SMOTE: synthetic minority oversampling technique; SVC: support vector classifier; XGBoost: extreme gradient boosting.





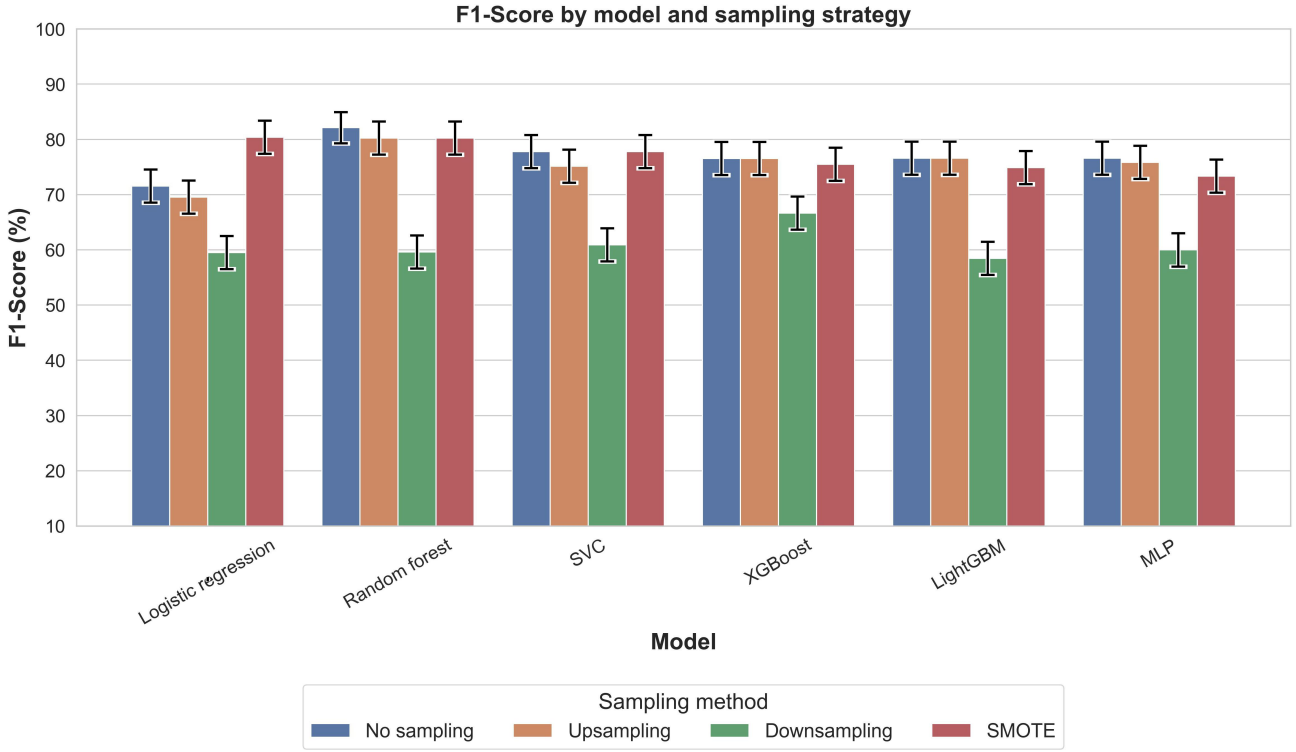


Figure 3. Comparison of accuracy across models and sampling methods for outcome nocturnal sleep duration. Accuracy represents the overall proportion of correct predictions, combining both positive and negative cases, and provides a broad measure of model correctness. LightGBM: light gradient boosting machine; MLP: multilayer perceptron; SMOTE: synthetic minority oversampling technique; SVC: support vector classifier; XGBoost: extreme gradient boosting.

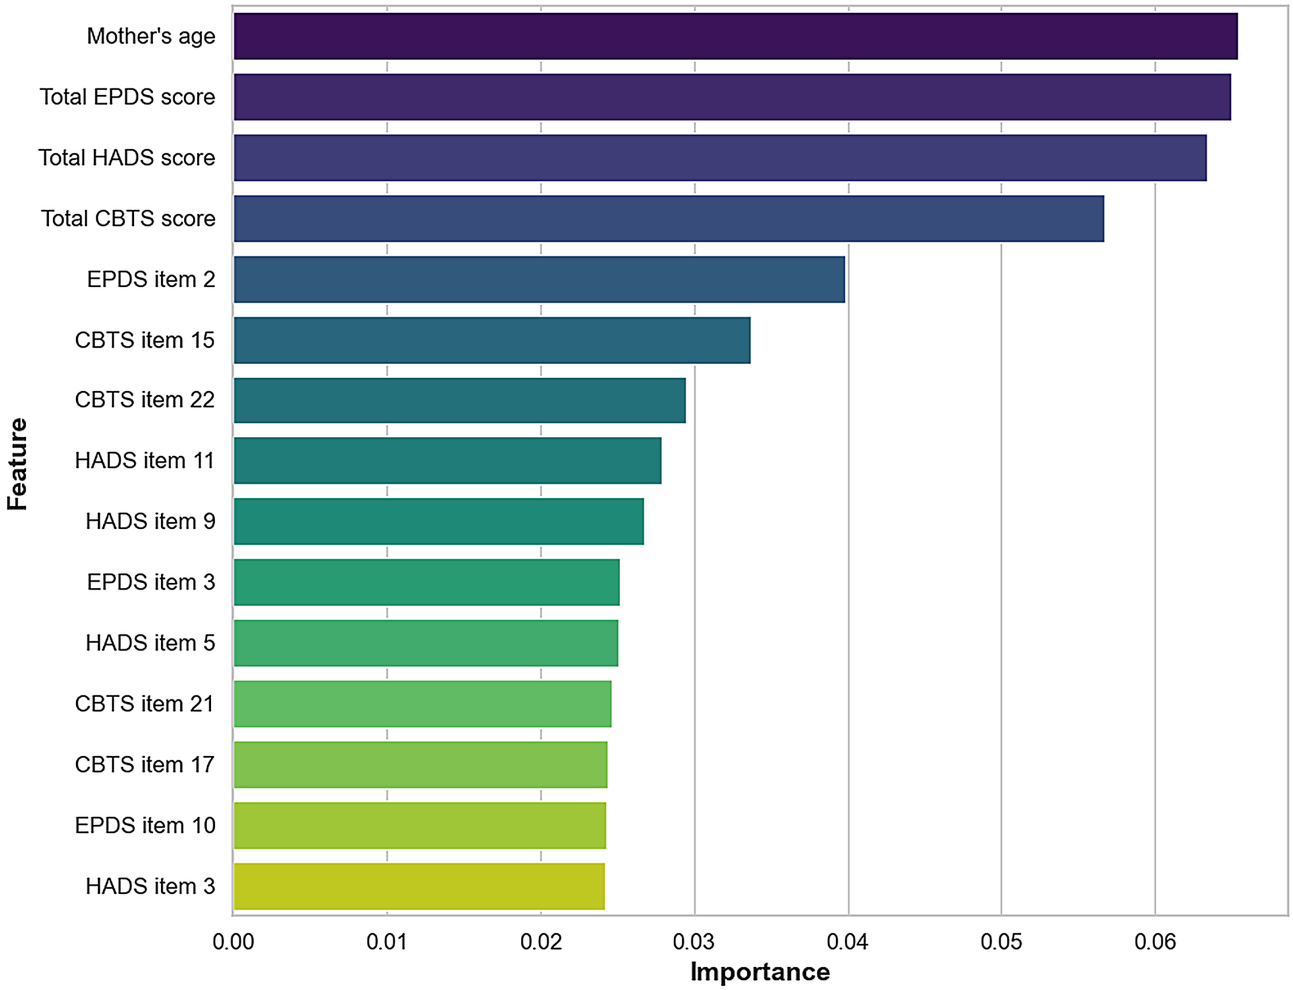
XSL•FO
RenderX

Figure 4. Comparison of F_1-score across models and sampling methods for outcome nocturnal sleep duration. The F_1-score balances precision and recall, making it a valuable metric for assessing model performance in the context of imbalanced datasets. LightGBM: light gradient boosting machine; MLP: multilayer perceptron; SMOTE: synthetic minority oversampling technique; SVC: support vector classifier; XGBoost: extreme gradient boosting.



Feature Importance Analysis

Figure 5 shows the most influential predictors of short nocturnal sleep duration: maternal age and total scores on the EPDS, HADS-A, and CBTS. Individual items also contributed meaningfully, particularly EPDS Item 2 (I have looked forward with enjoyment to things) and CBTS Item 15 (Feeling detached from others). To further probe how individual feature values contributed to predictions for the best-performing model, we examined SHAP summary plots for the nocturnal sleep outcome (Multimedia Appendix 1). These global SHAP patterns were broadly consistent with the main feature-importance rankings and illustrate how higher maternal symptom scores tend to shift predictions toward increased risk of nocturnal sleep disturbance.

XSL•FO
RenderX

Figure 5. Feature importance analysis for outcome nocturnal sleep duration. EPDS: Edinburgh Postnatal Depression Scale; HADS: Hospital Anxiety and Depression Scale; CBTS: City Birth Trauma Scale.

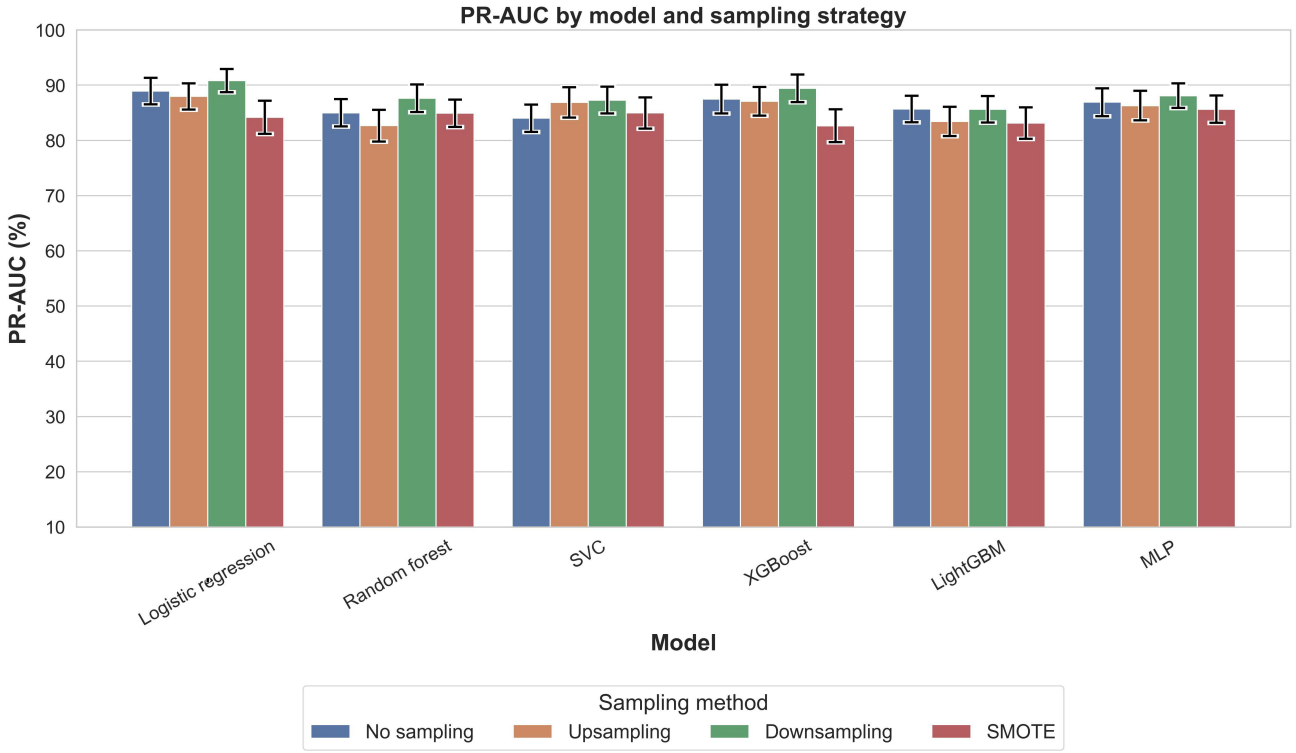
Prediction of Frequent Night Awakenings

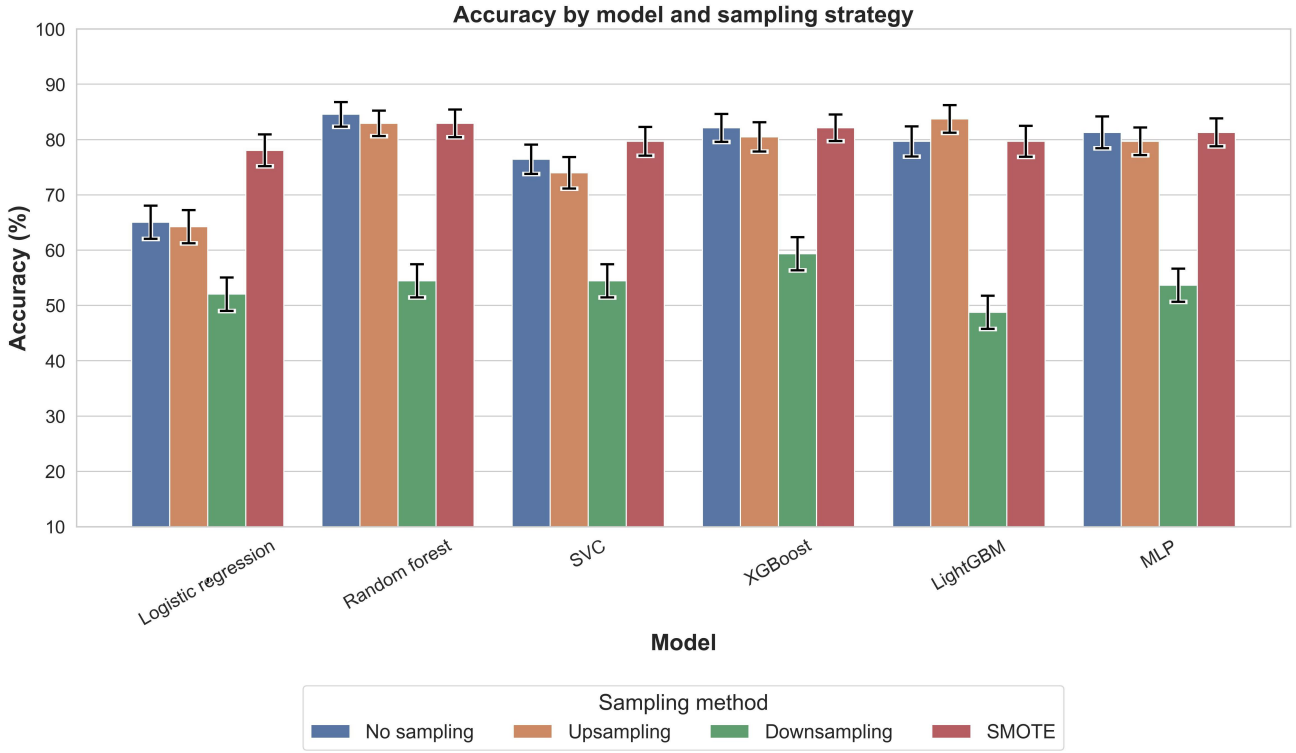
Models Performance

Figure 6 reports PR-AUC for predicting night awakenings frequency across models and sampling strategies. All models performed well, typically exceeding 0.83, with logistic regression highest (0.91) and MLP close behind (0.89). Figure 7 shows accuracy, with random forest without sampling highest (0.85) and MLP and XGBoost without sampling at 0.81; downsampling reduced accuracy for all models. F_1-scores (Figure 8) mirrored accuracy, with MLP and XGBoost without sampling at 0.76 and random forest with SMOTE at 0.78. Models trained on downsampled data had the lowest F_1-scores, underscoring the performance cost of sample reduction despite improved class balance.

XSL•FO
RenderX

Figure 6. Comparison of the precision-recall area under the curve (PR-AUC) across models and sampling methods for outcome night awakenings frequency. LightGBM: light gradient boosting machine; MLP: multilayer perceptron; SMOTE: synthetic minority oversampling technique; SVC: support vector classifier; XGBoost: extreme gradient boosting.





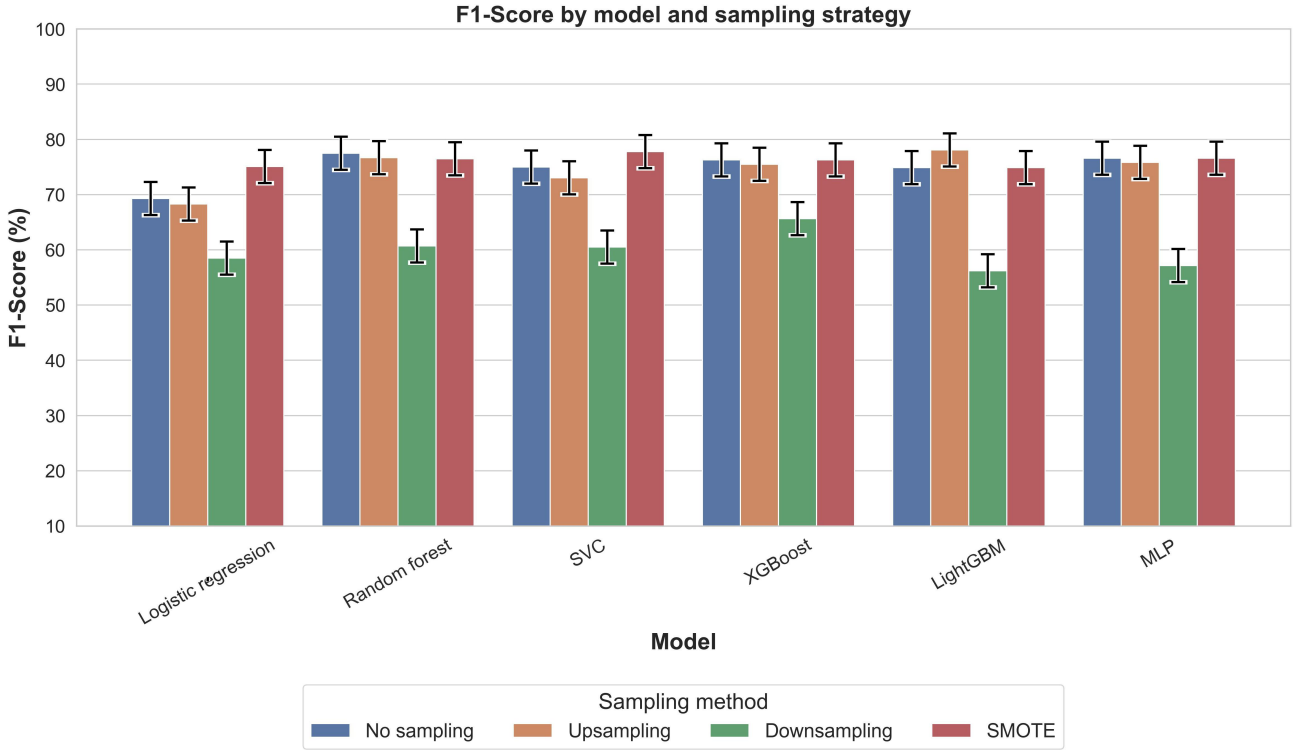


Figure 7. Comparison of accuracy across models and sampling methods for outcome night awakenings frequency. LightGBM: light gradient boosting machine; MLP: multilayer perceptron; SMOTE: synthetic minority oversampling technique; SVC: support vector classifier; XGBoost: extreme gradient boosting.

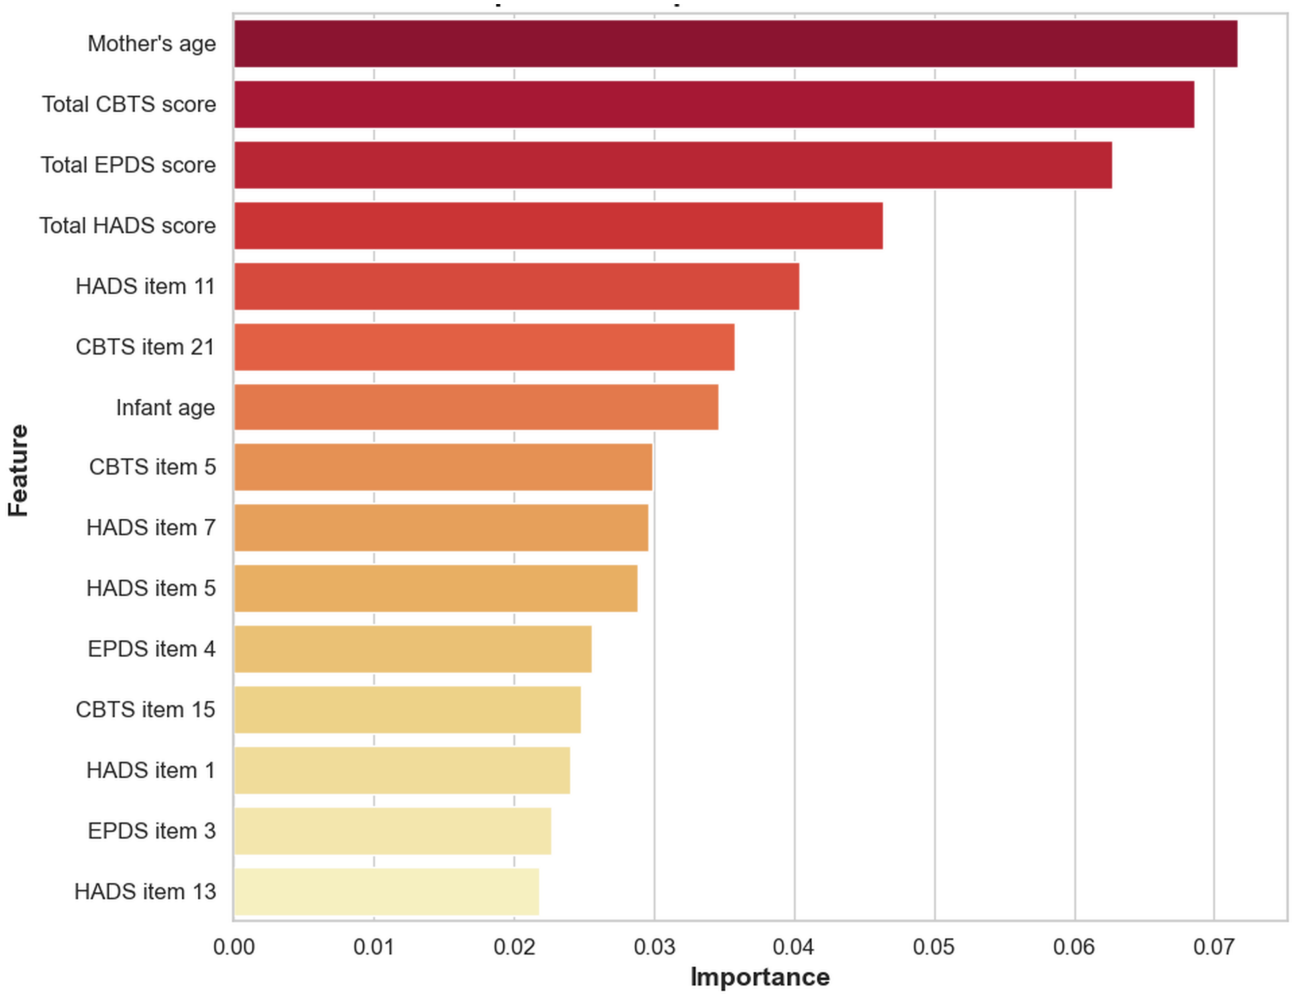
Figure 8. Comparison of F_1-score across models and sampling methods for outcome night awakenings frequency. LightGBM: light gradient boosting machine; MLP: multilayer perceptron; SMOTE: synthetic minority oversampling technique; SVC: support vector classifier; XGBoost: extreme gradient boosting.



Feature Importance Analysis

Feature importance analysis identified the most influential predictors of elevated night awakening frequency (Figure 9). As with nocturnal sleep duration, maternal age and total EPDS, HADS-A, and CBTS scores were top predictors. Individual items also contributed, notably HADS-A Item 11 (I feel restless and cannot seem to stay still) and CBTS Item 21 (Having difficulty concentrating). Infant age also emerged as a relevant predictor. An analogous SHAP summary plot for night awakenings (Multimedia Appendices 1-3) confirms the prominence of MMH features and illustrates how variations in these scores and sociodemographic factors shift individual predictions toward higher or lower night-awakening risk.

Discussion

Key Findings

This study evaluated the utility of postpartum MMH measures in predicting infant sleep patterns using an ML approach. Notably, supervised ML models trained on standardized psychological screening instruments (EPDS, HADS-A, and CBTS), combined with basic demographic and maternal variables, demonstrated high predictive accuracy for both outcomes: insufficient nocturnal sleep duration and frequent night awakenings. These findings indicate the feasibility of using MMH symptoms to identify infants at risk for suboptimal sleep patterns. It also confirms the feasibility of integrating ML tools into postpartum care pathways to facilitate early risk identification.

Predictors of Infant Sleep Patterns

Maternal age emerged as a top predictor for both outcomes, potentially reflecting links with parenting experience, physiological resilience, and contextual factors such as social support and caregiving efficacy. Prior work associating younger age with higher postpartum depression and poorer infant sleep [7,31] is consistent with its predictive strength in our models.

Total scores from the EPDS, HADS-A, and CBTS were among the most influential features in both models. Higher total EPDS scores indicate more severe postpartum depressive symptoms, which can impact maternal responsiveness and infant sleep regulation. Elevated anxiety levels (HADS-A) in mothers may lead to increased nighttime interactions, potentially disrupting infant sleep. Additionally, higher CBTS scores reflect greater CB-PTSD symptoms, which can affect maternal-infant bonding and sleep routines. These aggregate scores likely reflect the cumulative burden of postpartum psychological distress, which has been linked in prior research to disruptions in maternal caregiving behavior, nighttime responsiveness, and the emotional climate surrounding infant sleep routines [13,32,33].

Beyond aggregate symptom scores, several individual questionnaire items provided fine-grained insights. For example, EPDS Item 2 (“I have looked forward with enjoyment to things”)—a measure of anhedonia—was highly predictive of short nocturnal sleep duration. Lower scores on this item suggest anhedonia, a core symptom of depression, which may influence maternal engagement in establishing infant sleep routines. Similarly, CBTS Item 15 (“I felt distant or cut off from other people”) was ranked highly predictive of short nocturnal sleep duration, suggesting that maternal emotional withdrawal and social detachment, characteristic of childbirth-related trauma, may negatively impact the ability to establish secure and consistent nighttime routines.

XSL•FO
RenderX

In the models predicting frequent night awakenings, several additional features emerged as specific to this outcome. These included HADS-A Item 11 (“I feel restless and can’t seem to sit still”) and CBTS Item 21 (“I had difficulty concentrating”), both of which reflect maternal hyperarousal and cognitive dysregulation. These symptoms may manifest in heightened maternal vigilance or difficulty in promoting infant self-soothing, thereby contributing to fragmented infant sleep. Infant age also appeared as a differentiating predictor for this outcome, likely reflecting developmental maturation of sleep consolidation and age-dependent thresholds used in classifying night awakening frequency.

Research and Clinical Implications

From a research perspective, this study illustrates the value of combining symptom-level data with advanced modeling approaches to move beyond correlational frameworks and toward predictive analytics in maternal–infant health. The identification of both composite scores and individual symptom items as key predictors offers a granular understanding of how distinct psychological dimensions—such as anhedonia, emotional detachment, and hyperarousal—may differentially impact infant sleep regulation. These findings advocate for future investigations that examine not only the additive burden of MMH symptoms, but also the specific affective and cognitive pathways through which maternal distress shapes caregiving practices and infant behavioral development. Because MMH and infant sleep outcomes were assessed at the same time point, our models characterize concurrent statistical associations rather than temporal or causal effects. In this context, we use the term “prediction” to denote out-of-sample statistical prediction within the cross-sectional dataset, not longitudinal forecasting. The original analysis of this dataset by Sandoz et al [12] examined the cross-sectional associations between MMH symptom profiles and infant sleep outcomes using traditional statistical methods. In contrast, the present study focuses exclusively on evaluating the predictive performance of supervised ML models that use these MMH measures to classify infant sleep outcomes. Longitudinal studies are particularly needed to clarify the temporal sequence between MMH symptom fluctuations and changes in infant sleep architecture. Moreover, item-level granularity opens avenues for psychometric refinement of postpartum screening instruments, enabling the development of targeted subscales that better predict specific infant outcomes.

Integrating wearable technologies (eg, smartwatches, sleep trackers, biosensors) could passively capture continuous physiological and behavioral data from mothers and infants, reducing reliance on retrospective self-report. When combined with symptom-level psychological data, these rich data streams may improve ML predictive accuracy, enable earlier detection of risk patterns, and support more responsive, personalized interventions.

From a clinical perspective, our findings are best viewed as proof of concept for generating individualized risk scores rather than as a ready-to-deploy screening tool. In practice, such risk scores could be integrated into routine postpartum or well-baby contacts to flag mother-infant dyads who may benefit from closer follow-up (eg, additional monitoring visits or phone check-ins), brief psychoeducation on infant sleep and maternal self-care, targeted support around bedtime routines and soothing strategies, or referral to perinatal mental health services for more structured interventions (such as brief CBT-based programs, parenting support groups, or trauma-focused care where indicated). The exact decision thresholds would need to be codesigned with clinicians and policymakers, balancing sensitivity (minimizing missed high-risk dyads) against specificity and available resources. Our analyses therefore focus on overall discrimination metrics (eg, PR-AUC, F_1) rather than on a single “optimal” cut-off; future work should calibrate and validate context-specific thresholds and decision rules in real-world postpartum care pathways. In addition, findings from this study may inform the design of preventive intervention trials. For instance, trials could test whether tailoring interventions to specific symptom clusters (eg, anhedonia-focused therapies for mothers at risk of short infant sleep duration) yields superior outcomes. Finally, these results highlight the importance of interdisciplinary collaboration—integrating mental health, pediatrics, and data science—to advance personalized, responsive, and developmentally informed postpartum care that promotes long-term maternal and infant well-being.

Limitations and Future Directions

Several limitations should be carefully considered when interpreting the findings of this study.

First, the data relied entirely on maternal self-report questionnaires, which introduces potential response and recall biases. Mothers experiencing psychological distress may perceive or report their infant’s sleep differently, potentially inflating associations between MMH symptoms and infant sleep disturbances due to shared method variance. Furthermore, infant sleep during the first year is influenced by a complex interplay of biological, environmental, and caregiving factors. The exclusive focus on MMH, without integrating other relevant variables such as infant temperament, feeding methods, family routines, or the home sleep environment, limits the comprehensiveness of the predictive models. Future studies should incorporate multimodal, multi-informant data sources, including reports from partners or caregivers and objective sleep measures such as actigraphy or polysomnography, alongside contextual and behavioral variables to more accurately capture the multifactorial nature of infant sleep regulation.

Second, the analysis was limited to 409 mother-infant dyads, all recruited from a single university hospital in Switzerland. This relatively modest sample size and geographically restricted setting may limit the generalizability of the findings to broader, more diverse populations. Sociocultural factors, health care systems, parental practices, and support structures can vary significantly across regions and may influence both MMH and infant sleep patterns. Future studies should validate these predictive models using larger, more heterogeneous samples across multiple countries and health care settings to ensure greater external validity and applicability of the results.

Third, the cross-sectional design limits causal inference. Although we examine associations between MMH symptoms and infant sleep, we cannot determine directionality or

XSL•FO
RenderX

temporality. MMH may influence infant sleep, but the reverse is also plausible, with persistent sleep disturbances worsening maternal distress. Longitudinal studies are needed to disentangle these bidirectional effects and to capture trajectories of MMH and infant sleep over time.

Conclusions

This study demonstrates the feasibility and utility of applying supervised ML models to postpartum MMH symptom measures, together with basic maternal–infant characteristics, to predict infant sleep outcomes—specifically nocturnal sleep duration and night awakening frequency—during the first year of life. The combination of high-performing models and consistent variable importance patterns suggests that both maternal psychological well-being (eg, depressive, anxiety, and CB-PTSD symptoms) and non–mental-health factors such as maternal and infant age are associated with infant sleep patterns in this sample. By integrating scalable mental health screening tools with predictive analytics, this approach holds promise for early identification of at-risk dyads and for informing targeted, preventive interventions that support both maternal and infant health outcomes.

Data Availability

The data used in this study are publicly available and can be accessed through the Zenodo repository [11]. The code used is available at GitHub [34].

Abstract

Background: Parents are increasingly using infant feeding apps (IFAs) for information and decision-making related to breastfeeding and other aspects of their baby's care. Few studies have explored how users conceptualize data privacy risks in relation to IFAs and how concerns are balanced with app use.

Objective: This qualitative study forms part of the Infant Feeding App project exploring how IFAs influence parent-child communication in Australian families. A focus of this investigation was to explore mothers' understanding of the terms and conditions associated with the use of IFAs and their data privacy concerns.

Methods: We included first-time parents of children aged 0 to 4 years who were breastfeeding at the time of the first interview and previously or currently used 1 or more IFAs. Twenty-four participants completed the first-round interview; of those, 22 returned for a second-round interview approximately 6 months later, and 7 participated in the focus group discussion. Reflexive thematic analysis was used to analyze the data.

Results: This paper draws primarily on findings from the key category of "Data and/or Privacy Practices." This category was further refined into 2 main themes: lack of awareness or acceptance of the terms and conditions associated with the mobile app and the risk mitigation behaviors mothers took to protect their privacy.

Conclusions: Although mothers were aware of the privacy risks associated with IFAs, they nonetheless continued to engage with them, reflecting the broader growth in digital technology use. This paper has highlighted that privacy, a fundamental human right, is at risk when mothers share personal and child-related data through digital apps. Importantly, mothers' willingness to use these applications despite perceived concerns highlights the tension between perceived utility and potential risks. A call for a move toward privacy by design, transparency in privacy policies, and an approach of nonalienation in the use of data is called for.

Introduction

The number of infant feeding apps (IFAs) available to parents is growing, offering information to guide breastfeeding decisions and other aspects of care [1]. These apps typically enable the recording of feeding schedules and intake, sleeping patterns, growth metrics, and developmental milestones. The apps aim to offer timely support for women by enabling remote monitoring and information sharing throughout their pregnancy and the postpartum period [2-4]. IFAs have the potential to support timely access to information and have been reported as easy to use and create access to accurate information [5].

A recent randomized controlled trial in Turkey [5] showed that the use of IFAs influenced mothers' breastfeeding experiences in a positive manner, with users reporting fewer breastfeeding-related difficulties and higher rates of exclusive breastfeeding. IFAs have been used as supportive tools for promoting early initiation and continuation of breastfeeding [6] and exchange of knowledge among parents [7,8]. Other studies suggest that the use of IFAs is perceived by some parents as an

XSL•FO
RenderX

indicator of "good" parenting practices, or what has been termed "tracking-as-care" [9,10].

In Australia, parents have used IFAs to track their child's activities and to assist them with decision-making [1,11]. IFAs have been described as enhancing parental knowledge acquisition [6] and improving parental confidence [1], yet consensus across the literature on the perceived value of IFAs remains difficult to achieve.

Concerns have been noted in relation to the quality and accuracy of the content and the functionality of IFAs [12,13]. These issues are compounded by the scarcity of empirical evidence on data confidentiality and privacy when using mobile and web apps [14]. The use of IFAs often entails continuous input of personal data, including feeding times, infant weight, sleep cycles, and health behaviors that may raise concerns about the opacity of data privacy policies and the extent to which parents understand or consent to data sharing practices [4]. To deliver their functions, IFAs collect a wide range of data that may include parent-related data and personally identifiable information, such as names, birth dates, email addresses, and location. Mortensen and Lomborg [15] have characterized this issue as the continuous generation of digital traces or "data selfies" through engagement with mobile self-tracking apps (p. 6013).

A further issue is the potential for third parties without the explicit knowledge of the user to access and use data. Lupton and Michael [16] found that people recognized the value that could be derived from their own personal data, as well as from the collective insights generated when their data were integrated into aggregated datasets, benefiting both themselves and others. However, they found that people expressed concerns or suspicion about how their data might be used by others and what ultimately happens to their data. Areas for further investigation in relation to these areas include the balance between sharing personal data, the value to the individual as a result, and data privacy.

Normalizing the datafication of everyday activities, such as sleeping data or feeding times (parent and child data), has been raised as a form of dataveillance [8,11]. The acceptance of apps such as IFAs can be argued to normalize the heightened surveillance of both women's and children's bodies [9]. The creation of a data trace across the lifespan is relatively new, with children becoming digital citizens sometimes before they are even born through pregnancy apps and social media postings [17]. Areas for further exploration include: when does personal dataveillance become too intrusive, and how do we balance the growing digitization of children in relation to the sharing, selling, and commodification of data?

While the use of IFAs may assist in developing innovative interventions to support infant feeding practices, the need to develop a more nuanced understanding of how parents perceive and manage issues of data privacy is needed. Therefore, this paper aimed to explore mothers' understanding of the terms and conditions associated with the use of IFAs and their data privacy concerns.

Methods

Design

This study is part of an ongoing research project, "The parent-child communication implications of IFAs," that aims to better understand the impacts of IFAs on parent-child communication among Australian families. The project broadly problematizes the inclusion of a screen as a novel component within early processes of infant feeding, but also acknowledges the potential benefits IFAs offer, especially to first-time parents. A key aim was to explore the motivations and concerns that support parents' use of IFAs and the reasons why some parents might choose not to use them or might discontinue their use. Of particular relevance to this paper were motivations and concerns around privacy practices and terms and conditions.

The data used in this study were collected using a descriptive qualitative design comprising 2 rounds of interviews followed by focus group sessions. The data reported here are derived from 1 of the 2 focus groups conducted as part of a larger study. For inclusivity and flexibility in recruitment, participants were able to join either session according to their convenience. Data collection was concluded once thematic saturation was reached and when additional sessions were unlikely to yield new insights or generate further data.

Having multiple points of data collection created a degree of semilongitudinal data to capture parents' evolving views, while focus groups have the potential to expand data as participants' views may be supported or challenged by engaging in collective dialogue with others [18]. A semistructured interview guide was developed with questions designed to explore parents' data privacy perspectives in the use of IFAs and in their broader digital parenting (Textbox 1).

Textbox 1. Main questions from the interview guide.

The following were the semistructured interview questions:

1. What factors influence new parents' choice to use or not use infant feeding apps?
2. How do parents use infant feeding apps and what do they see as the benefits and drawbacks?
3. What understandings do parents have regarding the terms and conditions of their app use, and the resulting reuse of data and harnessing of data flows?
4. When, how, and why do parents start or end the use of infant feeding apps as part of their infant feeding practices?

XSL•FO
RenderX

Participants and Recruitment

A total of 24 English-speaking participants were interviewed in 2024. Although recruitment targeted parents of infants aged 0 to 4 years, the actual age distribution was 1 to 10 months at the time of the first round of interviews. The IFA project collected qualitative data from participants through 2 rounds of semistructured interviews, followed by a series of focus groups. Of the initial 24 participants who took part in a first-round interview, 22 returned for a second-round interview approximately 6 months later, with 7 returning for a focus group. All participants were breastfeeding mothers of children at the time of the first round of interviews. A total of 46 interviews and 2 focus groups were conducted online between mid-2023 and mid-2024. Recruitment took place online via social media, predominantly through Facebook mothers' groups, using the snowball method. Participants received an AUD $50 (US $33) gift card at each data collection point.

Data Collection

The semistructured interviews were conducted online. The interviews were recorded with a digital audio-recording device and transcribed by the same researcher who performed the interviews. The interviews lasted a mean of 45 (SD 15) minutes.

Analysis

Interviews and focus groups were transcribed and deidentified before coding in NVivo software (version 1.7.1; Lumivero). Before coding, the research team read through the interviews several times to become familiar with the transcripts and achieve deep immersion in the data. Subsequently, initial codes were systematically developed inductively and organized into subthemes and overarching thematic categories. Multiple researchers assisted in reviewing and examining the coded material within each theme and assisted in defining and refining the themes through the writing up of this study. Of the 5 final codes, the most relevant to this paper is number 4, "Data and/or Privacy Practices," which was divided into further subcategories and themes.

To ensure rigor, interpretations of the coded data emerged from ongoing iterative discussions between all authors of the paper using reflexive thematic analysis [19]; as such, the authors acknowledge that their differing disciplinary and lifeworld perspectives influence their readings of the data, and that more comprehensive readings are potentially made accessible through interdisciplinary dialogue. This study employed reflexive thematic analysis to systematically elucidate patterns of meaning within parents' narratives. The analytic process was strengthened by deliberate reflexivity, enabling critical examination of researchers' preconceptions and fostering methodological transparency. Furthermore, the integration of surveillance theory as an interpretive framework informed the development of latent codes, thereby enhancing the conceptual depth and analytic rigor of thematic constructs.

In the context of this research, IFAs constituted any smartphone app that assisted parents to support or track their children's feeding routine; overarchingly, this meant breastfeeding mothers; however, as the data are semilongitudinal, some participants were in the process of shifting to solid food. The most common IFAs used by parents were "Huckleberry" and "Solid Starts." Of the 24 participants, 6 either did not regularly use IFAs at the time of the research or had never regularly used IFAs.

Ethical Considerations

Data collection was undertaken by researchers from the Edith Cowan University node of the Australian Research Council Center of Excellence for the Digital Child under the oversight of Chief Investigator Professor Lelia Green. The project received approval from Edith Cowan University's Human Research Ethics Committee (approval number 2022 - 03677-GREEN) and was funded by the Australian Research Council Center of Excellence for the Digital Child (project number CE200100022).

All eligible participants were provided written information about the study, and their consent was obtained before data collection.

Results

Participant Characteristics

A total of 24 English-speaking participants were interviewed in 2024. Participant characteristics are reported in Table 1. Infants ranged in age from 1 month to 10 months at the time of the first interview, with balanced representation across genders and the highest proportion observed at 7 months. The duration of IFA use varied between 6 and 24 weeks at the time of the last interview and/or focus group. The majority of participants were based in Western Australia (n=13), with additional representation from New South Wales (n=4), Queensland (n=4), Victoria (n=2), and the Australian Capital Territory (n=1). Across the sample, patterns of parental engagement with IFAs were diverse. While some participants reported minimal or selective use, others actively engaged with multiple apps. Huckleberry, Solid Starts, and Wonder Weeks were the most frequently used.

[b]IFAs: infant feeding apps.

[c]Not applicable.

Overview

Across the entire project, 4 initial codes were generated through NVivo software (version 1.7.1). The final initial themes included the following:

1. Choice to adopt IFAs (1.A) or to avoid them (1.B).
2. Use of IFAs for record-keeping (2.A) or as a source of support (2.B).
3. Use of alternatives and other non-IFAs (3.A) or non-app modes of support (3.B).
4. Data privacy, including awareness or acceptance of terms and conditions (4.A), experiences or knowledge of risk-changing events, such as hacking or political issues (4.B), and ambivalence toward privacy (4.C).
5. Breastfeeding beyond the IFA context, which included positive (5.A) and negative aspects (5.B).

This paper specifically focuses on Theme 4: Data Privacy, which was refined through reflexive thematic analysis across 3 iterative cycles. During this process, the 3 initial codes were refined and reorganized into two main themes:

1. Awareness and/or acceptance of terms and conditions (subthemes included "data privacy laxity and normalization" and "benefits outweigh risk").
2. Risk mitigation behaviors.

Theme 1: Awareness and/or Acceptance of Terms and Conditions

Major Study Themes

A major theme that emerged from the mothers' interviews and the focus group was mothers' awareness of the privacy risks associated with IFAs, coupled with a pragmatic acceptance of the terms and conditions governing their use. Two subthemes reflected this. The first included "Data privacy laxity and normalization," where mothers normalized and resignified the routine acceptance of surveillance and minimal engagement with terms and conditions. The second included "Benefits outweigh risks," where the practical utility of these apps outweighed potential risks despite underlying discomfort.

Subtheme 1: Data Privacy Laxity and Normalization

Many participants expressed awareness of data collection and privacy risks associated with IFAs. However, they often described a sense of resignation or acceptance toward these practices, particularly in relation to lengthy and complex terms and conditions. Rather than carefully reviewing such documents, most participants reported clicking "accept" as part of everyday app use, recognizing the trade-off between convenience and privacy. Lydia, for example, shared:

> *I just click accept, you know what I mean? I'm not going to put photos on there [...] my understanding was limited.* [Lydia, 7-month-old daughter, uses one IFA, ceased another at 3 wk]

Other participants also commented:

> *I don't normally think about data collection and privacy and stuff in apps; it's just so common, it's supposed to be so much more helpful in our lives […] I don't have time to sit there and read a 20-page long terms and conditions on your data collection processes.* [Bernadette, 5-month-old daughter uses two IFAs]

> *.....I can't say I've read the terms and conditions of every app that you use because who does? I go in with the assumption that nothing's private cause a lot of them.* [Helena, 6-month-old female, uses one IFA, ceased another at 6 wk]

One participant stated:

> *I assume that it's all aggregated data for sale.* [Helena, 6-month-old daughter, uses one IFA, ceased another at 6 wk]

For some mothers, the nature of the data input reduced their concerns in relation to privacy:

> *I don't feel as though I'm providing data that's too personalised, that's a threat I suppose to have on there. It's just times.* [Bernadette, 5-month-old daughter uses two IFAs]

Lucia shared a similar view, expressing little concern over data related to feeding or diaper changes:

> *I don't really think about the data in relation to the baby stuff. [...] How many times I'm getting my boob out or changing nappies, I don't really care if anyone knows.* [Lucia, 5-month-old son, uses two IFAs]

XSL•FO
RenderX

Many mothers described feeling resigned to the ubiquity of data collection across digital platforms, recognizing that similar practices occur on widely used services like Facebook and Google.

> *[...] we're so used to it (refers to data used for marketing) [...] once you search for one thing they feed you 10 other things related to it and I still use Facebook, I still use Google and everything so I probably would still use it but I would feel a little bit strange or uncomfortable with it, I guess.* [Cassandra, 6-month-old daughter, uses one IFA]

Hyacinth echoed these views, emphasizing that data collection through IFAs does not worry her because data are being collected from phones in general. She explained:

> *[...] I don't really care that much either. I think with data collection our data's being collected anywhere. Any time we pick up our phone, our data's being collected from somewhere, and I guess that kind of data that I'm entering into the app [...] I don't really see how they can use that in any – they can use it however they want; it's not really affecting anyone.* [Hyacinth, 5-month-old daughter, uses two IFAs, ceased another]

Interestingly, the wider policy environment shaped how some participants thought about privacy issues and helped normalize data sharing. This was highlighted in Babette's comment, which contrasted data privacy laws between the EU and Australia.

> *I really hate the EU data privacy laws...you have to repeat your information all the time because of data protection...that's one of the reasons why I decided to move back to Australia.* [Babette, 5-month-old female, uses one IFA, ceased another]

As several participants explained, this behavior reflected not ignorance but a pragmatic response to the demands of parenting and perceived inevitability of data sharing in digital environments. Mothers normalized data sharing, and strict rules were sometimes seen as frustrating rather than protective, reinforcing that surveillance of data was perceived as a normal part of everyday digital life.

Subtheme 2: Benefits Outweigh Risks

Participants spoke about their willingness to forgo privacy concerns in exchange for higher levels of perceived convenience. Some participants differentiated between digital apps, tolerating IFAs while expressing greater concerns about other platforms like Facebook and Instagram.

The majority of mothers described focusing more on the app's utility than on the potential data privacy violations. The utility of IFAs in health care contexts and everyday parenting often outweighed privacy concerns. Patty highlighted their value, stating:

> *When I would go to the child health nurse checkup, I would have all the data and there ready to go. I knew what my trends were, what the averages were.* [Patty, 8-month-old female, uses one IFA, ceased another]

The same participant reframed targeted advertising as supportive:

> *Being suggested a product, I think that's helpful for mum.* [Patty, 8-month-old female, uses one IFA, ceased another]

Cassandra expressed that despite knowing that her data were being collected, she would continue to use an app as well:

> *I've been reading a lot about the privacy of data in those apps which I also used when I was trying and pregnant...Obviously it's not such a concern that it's stopping me using it 'cause I'm still using it and putting in heaps and heaps and heaps of data.* [Cassandra, 6-month-old female, uses one IFA (INT1)]

Bernadette's comments provide further insight. In the early stages of using an IFA, she wasn't focused on privacy concerns as her primary goal was to reduce the mental load of caregiving:

> *In the beginning it probably wasn't something that I was thinking of; I was looking for something to take a mental load off.* [Bernadette, 5-month-old daughter uses two IFAs]

However, after experiencing a data breach that compromised her online accounts, she now views data privacy differently, though it wasn't a priority when she first started using the app.

Another mother added how common it is to overlook privacy considerations, reflecting on the convenience that IFAs provide and on prioritizing their baby's needs:

> *Yeah. I don't know if it would have stopped me from using it or not, but I don't think it would have stopped me from using it.* [Paris, 6-month-old son one IFA ceased at 5 months]

Elspeth and Felicia have never used an IFA but shared a similar experience, explaining that during the intense period of feeding, privacy was not a major concern and was not a consideration regarding whether to use an IFA or not. Although they did not use an IFA, they relied on other online resources. She said:

> *I haven't really thought about it collecting information so that probably hasn't been a primary concern for me.* [Elspeth, 1-month-old son, never used IFAs]

> *I wasn't thinking about privacy and data collection [...] I was thinking about what my baby needed from me at that time.* [Elspeth, 1-month-old male, never used IFAs (FG)]

> *I don't think I even thought about any concern about data privacy as something; again, I just think about what my baby needs.* [Felicia, 7-month-old female twins, has never used IFAs (FG)]

In retrospect, Elspeth was not sure her awareness of privacy concerns would have changed her behavior, noting that she uses other subscription services without much concern for data collection.

> *...It's such a complex world that's changing so much that I don't fully understand it enough. So, I don't*

XSL•FO
RenderX

> *know how worried I am about it at this point, I suppose.* [Elspeth, 1-month-old male, never used IFAs (FG)]

Others, like Semra, who used 2 IFAs, rationalize that if their data are used for improving services or targeted marketing, they would still use the app if the benefits outweigh the risks.

> *I think they use it to sell me something [...] that's fine if they found something that was helpful for me.* [Semra, 8-month-old daughter, uses two IFAs]

Overall, while some awareness of privacy risks related to IFAs exists, most mothers do not engage deeply with the terms and conditions. Concerns about data privacy, while present, are often outweighed by the perceived utility of the IFAs, leading mothers to continue using them despite reservations. As Bernadette illustrates, the focus remains on immediate caregiving needs, and the complexity of digital privacy in today's world makes it difficult for parents to fully assess or act on these concerns and rarely deter IFA use.

Another mother added that data sharing that led to greater good through research may justify data collection or their personal information being tracked:

> *...] if they took all that data and used it for research purposes then I'd be fine with it because it's not like it's identified data, it's all deidentified, really, they don't have anything.* [Semra, 8-month-old daughter, uses two IFAs]

This suggests that while some participants also demonstrated varying levels of concern over privacy issues among different digital apps, IFAs were perceived as being less invasive compared with other apps.

Collectively, both themes illustrate a tension between risk awareness and acceptance, underscoring how perceived utility often outweighs concerns about surveillance and data trails. While it is true that many users of smart and digital apps commonly skip reading terms and conditions, our findings extend understanding where mothers' quotations revealed how parents specifically interpret and negotiate such practices in the context of infant-feeding apps, as shown in the next section. For example, participants discussed privacy concerns and risk management in relation to their children's health, which reframes a general behavior into a context-specific act. Thus, while the behavior itself may be widespread, its meaning and implications in the domain of infant care are unique to this group.

Theme 2: Risk Mitigation Behaviors

Under this theme, mothers reflected on the measures they employed to mitigate their concerns around data privacy. This included various measures, such as selective disclosure when participants withheld or altered personal details, or avoiding child images or using shortened names.

Some mothers adopted privacy-conscious behaviors such as using pseudonyms or incomplete personal information (eg, incorrect birth dates) to reduce their exposure.

> *[...], I tend to not put anything majorly personal on these apps so I don't have my real name – I have my name but my shortened name so just Patty and [Joey] like I don't put very big identification things on there for that reason probably.* [Patty, 8-month-old daughter, uses one IFA, ceased another at 4 mo]

Similarly, Lucia emphasized her ability to control disclosure, stating:

> *We're pretty careful with any forms we fill out for the hospital... say don't add to my health record and things 'cause it just feels a bit creepy'.* [Lucia, 5-month-old male, uses two IFAs]

Several other mothers, such as Helena, Lauretta, and Semra, shared actions that reflected privacy-conscious behavior and increasing awareness of data vulnerabilities and concern over potential surveillance of their data:

> *[....], they won't let you use it unless you put in the name and the date of birth and that kind of thing, I just make it up, I use something different cause I'm like that doesn't matter. If they're going to give age-based recommendations then I'll change it by two days or something like they just don't need that info.* [Helena, 6-month-old daughter, uses one IFA, ceased another at 6 wk]

> *[....], I'm also probably mindful when I am putting things online that I don't put anything that's too disclosing about where I live or anything like that so they're not going to be getting any data that I wouldn't care if anyone knew.* [Lauretta, 6-month-old son, uses two IFAs]

Another participant echoed:

> *I probably didn't really care too much for Huckleberry and Solid Starts, things that I don't even put too much of my personal information in so it's not linked to my Facebook or any of my applications and I can choose whether I put in her real name, her fake name, a photo.* [Semra, 8-month-old daughter, uses two IFAs]

Overall, mothers' awareness of privacy risks generally did not strongly influence their behavior, and many admit they haven't given much thought to the potential risks. As Morgana noted, her concerns about data privacy increased after a Facebook hack, leading her to reduce her online activity:

> *I've pulled back on sharing a lot of information [...] I've deleted a couple of apps and signed out of them because of it.* [Morgana, a 7-month-old male, uses one IFA (INT1)]

Our findings suggest a dynamic interplay between awareness of surveillance, leading to selective disclosure and deidentification. It shows that mothers acknowledged vulnerabilities and privacy concerns, yet they actively negotiated their engagement and adopted everyday privacy practices that allowed continued use with unease.

Discussion

Principal Findings

In this study, we explored mothers' understanding of the terms and conditions associated with IFAs and their data privacy concerns. The first emerging theme was awareness and acceptance of terms and conditions. Our findings show that participants demonstrated awareness that engaging with IFAs involved data collection and potential privacy risk. Despite this, many described accepting terms and conditions without reading these in detail, often citing limited time or the perceived inevitability of such practices. For some, this acceptance was framed as a trust in implied digital security, while others expressed resignation, noting that data collection is now an unavoidable aspect of online activity. A few participants articulated the belief that "everyone's data are up for sale," reflecting a broader recognition that privacy compromises are inherent in the use of digital devices and apps.

Building on these insights, it is important to note that control over data remains a fundamental right. The Australian Competition and Consumer Commission's report [20] emphasized reforms to ensure consumers are informed and protected in how their data are used (p. 3). Privacy is negotiated through balanced disclosure with protection [21], but information shared through IFAs may persist, be widely distributed, and be repurposed in unintended ways [22-25]. Our findings show that while some participants acknowledged the potential of their data to be distributed or reused, most participants expressed acceptance of such practices as an unavoidable aspect of digital engagement. In Australia, the Privacy Act sets out 13 Australian Privacy Principles based on a notice and consent model, which places responsibility on individuals to manage their own personal information and to interpret complex privacy policies [26]. For many participants, reviewing such policies was unrealistic due to time constraints or trust in implied protections, a finding consistent with prior research [27]. These findings underscore the limits of privacy self-management and reinforce calls for a mandated "privacy by design" approach, embedding protections into platform development from the outset [28].

Digital privacy is critical for all users of platforms that collect personal data and is widely regarded as essential for protecting consumers from unwanted access and misuse [29].

Privacy carries a positive value, while invasion of privacy is seen as a violation of a protected interest. In this way, participants in this study reflected the broader social narrative that privacy should be protected in digital space [30]. This is consistent with the right to privacy in the digital age that was affirmed by the United Nations General Assembly and the Human Rights Council [31], requiring that any interference meet the principles of legality and proportionality, while noting that emerging technologies, such as artificial intelligence, can affect this right [32].

Despite these protections, many remain resigned to threats from big data, cloud computing, and profiling [33]. Participants in the study accepted that app-collected data could be commodified, expecting it might be used or sold. This raises complex questions about when online data are classified as public or private, whether their reuse constitutes intervention without consent, and how individuals' privacy can be safeguarded [34].

The second emerging theme was risk-mitigation behaviors, where participants described exercising a degree of control over the data they shared by adopting strategies to mitigate perceived risks. These included using pseudonyms rather than real names and obfuscating identifiers such as date of birth. Participants also constructed personal boundaries around what information they considered acceptable to disclose. For example, not sharing visual images was important to one mother, while another noted that the type of information shared, such as the number of feeds or nappy changes, did not feel too personal to share more widely.

Overall, participants perceived the benefits of engaging with IFAs as outweighing the potential risks. Many described a willingness to forgo privacy concerns in exchange for higher levels of perceived convenience. The majority of mothers described focusing more on the mobile app's utility than on the potential data privacy violations. Trust in the security of digital systems and a belief in having some control over the information shared contributed to this sense of acceptance. These findings highlight the complex interplay between utility and privacy trade-offs and are discussed in relation to current debates on data privacy in online environments.

Some participants in this study believed they could protect their privacy by altering key identifiers, such as date of birth. This highlights which types of information about themselves were considered more sensitive than behavioral data like feeding or changing routines. Obscuring personal information is not new and is practiced offline as well [35], with individuals deciding how much to reveal in different contexts.

Online, people sometimes create "Amateur Artists" [36] to protect their privacy. These disguises can range from complete reinvention [37] to small changes, like those seen in this study, where mothers adjusted details but still felt their data reflected real experiences while giving them some protection. Not everyone supports this practice. Zuckerberg argues that having more than one identity shows a lack of integrity and that people should present a single, authentic self online [38,39]. Similarly, Google's Eric Schmidt claimed that "Innocent people have nothing to hide" [40], suggesting privacy concerns are unnecessary.

Our finding is that self-disclosure is complex, with different views on what counts as personal and sensitive information. Literature highlights dimensions such as the depth and value of what is shared [41]; for example, demographic details may be seen as less sensitive than private photos or emotions. However, individuals may share private data unknowingly due to limited risk awareness [42,43], lack of knowledge about ways to protect data [44], or not being aware of how data are distributed postsubmission [45].

Consent remains central to the use of digital data; reliable collection depends on mutual respect and trust between parties [30]. IFAs that require login, membership, or subscription create

XSL•FO
RenderX

a sense of "perceived privacy," yet most participants in this study did not expect their data to be shared beyond the app and may not have realized this was possible [46]. Consistent with earlier reports, concerns relating to the security of their data have led some users to stop or delete IFAs [47,48], but research on the link between privacy and security in mobile apps remains limited [49,50]. Evidence shows that privacy risks reduce trust in app security, while clear policies can strengthen it. In the health context, privacy can only be assured where individuals control their information and prevent unnecessary disclosure [51,52]. Digital safety is increasingly recognized as essential, particularly for children and young people [53]. Building digital safety requires self-efficacy, knowledge, and skills related to managing risks. Awareness of digital safety can assist parents in adopting strategies to safeguard themselves and their families [53].

The findings of this study were limited by the restricted demographic data collected and the sample profile. This study was limited to English-speaking Australians, breastfeeding mothers recruited mainly via Facebook, which may limit diversity and generalizability. This recruitment strategy may have introduced selection bias and limited the diversity of perspectives, particularly among culturally and linguistically diverse parents or those with lower levels of digital literacy. Consequently, the findings should be interpreted within the context of the participant profile and may not fully reflect the experiences of caregivers from different backgrounds.

Another limitation is the absence of information on socioeconomic and educational data, which further constrains contextual interpretation. These factors may have influenced perspectives on digital privacy and engagement with IFAs, and their absence restricts the ability to fully contextualize findings. However, the study was designed to focus on parents' experiences and perceptions of IFA use rather than to compare outcomes across demographic groups. While this approach provided valuable insights into usage patterns and parental perspectives, future studies would benefit from including broader demographic variables to capture how diverse backgrounds may shape digital practices and privacy concerns. Use of mixed methods and longitudinal approaches can enrich data by combining both qualitative and quantitative insights into privacy literacy and behaviors.

Conclusions

Parents of young children carry dual responsibilities as advocates and primary caregivers [54], and many now rely on digital apps, such as IFAs, to track and manage health behaviors. Breastfeeding as a socially and emotionally charged practice has become increasingly mediated through digital tools, reflecting the demand for accessible, time-sensitive information [55,56]. While such technologies present opportunities for increased access to education and health promotion [57], they also introduce risks that require careful negotiation [53]. Our study shows that mothers' engagement with IFAs is shaped by 2 key dynamics: awareness and acceptance of terms and conditions and risk-mitigation behaviors. This paper has highlighted the varying levels of awareness among mothers of how data about themselves and their child can be used and their expectations of how personal information will be kept confidential and secure through their engagement with a breastfeeding mobile app. The findings highlight the need for action toward privacy by design, transparency in privacy policies, and nonalienation in relation to the use of data. The use of IFAs reveals a paradox: mothers acknowledge the inevitability of data collection, yet actively resist through boundary-setting and risk-mitigation. Embedding privacy by design and fostering genuine trust in IFAs is essential to protect both parental and child well-being

Our findings highlight the importance of transparent privacy policies and respect for contextual integrity and user-centered safeguards that enhance digital safety, protect against hidden risks, and ensure accountability in data use.

Acknowledgments

We sincerely thank all participants for their time and willingness to share their valuable perspectives in this study. All authors contributed equally to the manuscript and approved the final version. The authors confirm that no content, data analysis, or substantive interpretation was generated by AI; however, they acknowledge the use of generative AI (Microsoft Copilot; version 1.0) for language refinement and clarity editing.

Abstract

The Daniel Stern concept of the motherhood constellation describes a distinctive psychic organization that emerges in the transition to motherhood, structured by 3 relational discourses and 4 thematic concerns: safeguarding infant life and growth, establishing primary relatedness, securing a matrix of support, and reorganizing maternal identity. Formulated in the mid-1990s, this framework preceded the pervasive integration of smartphones, social media, and artificial intelligence (AI) into everyday life. Contemporary mothers now care for infants in environments saturated by online information, connectivity, and AI-mediated support, raising questions about how these factors participate in and reshape the Stern architecture. This theoretical paper argues that smartphones and AI function not as neutral tools but as systemic actors within the motherhood constellation. Drawing on the Stern model, attachment theory, mentalization research, ecological perspectives, sociotechnical theory, and empirical work on technoference, maternal smartphone use, digital parenting, online maternal communities, and AI-based mental health interventions, we conceptualize digital technologies as entities whose affordances co-structure maternal psychic life. Available findings indicate that they simultaneously expand access to information and support, introduce interactional disruptions, and create new, partially algorithmic matrices of support, with effects moderated by patterns of use, maternal reflective functioning, child characteristics, platform design, and socio-structural conditions. We propose a technologically mediated motherhood constellation, in which smartphones and AI enter all 3 discourses (mother–own-mother, mother–self-as-mother, and mother-infant) and all 4 themes. Rather than asking whether technology is "good" or "bad" for motherhood, we outline a spectrum from technology-enhanced to technology-disrupted constellations and derive implications for clinical practice, research, technology design, and social policy.

Introduction

In *The Motherhood Constellation*, Stern [1] describes a specific configuration of psychic life that comes to the foreground during pregnancy and early motherhood, organizing the mother's experience around the infant and reshaping her relations to the past, present, and imagined futures. This constellation is structured by concerns about the infant's life and growth, the establishment of a primary emotional relationship, the securing of a sufficiently reliable matrix of support, and the integration of "mother" into the woman's broader identity. These thematic concerns are enacted within 3 interlocking discourses: the mother's dialogue with her own mother and the internalized maternal figure; her ongoing dialogue with herself-as-mother; and the dynamic, moment-to-moment interactional discourse with the infant [1].

Stern's [2] account is inseparable from his earlier work on infant experience and affect attunement, which conceptualizes infant-caregiver intersubjectivity as being built from microregulations of gaze, vocalization, touch, and rhythm. The motherhood constellation is therefore not an intrapsychic structure operating in isolation, but a relational organization coconstructed with the infant, the family, and the broader sociocultural environment. The matrix of support is not merely instrumental; it enters the mother's internal world as anticipated and remembered responses that scaffold her sense of being carried while she carries the child [1].

When Stern developed this model in the mid-1990s, everyday communication and support networks were still largely analog. Information about pregnancy and infant care was obtained from health professionals, printed manuals, and intergenerational transmission. Social support was anchored in copresent kin and

XSL•FO
RenderX

local communities. Since then, smartphone penetration has reached very high levels in high-income countries, and the early months of motherhood have become densely interwoven with digital media. Qualitative work by Lupton [3] shows that women routinely use websites, apps, blogs, forums, and social media as central resources during pregnancy and early motherhood, describing them as essential for managing anxiety, isolation, and informational uncertainty. Mothers report consulting online sources multiple times per day for questions about sleep, feeding, crying, and health, often before contacting professionals or relatives [4].

Parallel to this informational shift, a rapidly growing body of literature on "technoference" has documented that parental digital technology use can intrude into parent-child interactions in ways that reduce sensitivity and responsiveness, and is associated with child behavior problems [5]. The longitudinal work by McDaniel and Radesky [5] indicates bidirectional associations between parent technology use, parenting stress, and child behavior. Experimental adaptation of the still-face paradigm to smartphone use suggests that even brief episodes of maternal device engagement can elicit infant responses resembling those seen in classic still-face conditions, including increased negative affect and efforts to reengage the caregiver [6].

However, the same period has seen digital media emerge as vital support infrastructures. Online parenting communities provide emotional validation, practical advice, and a sense of belonging, especially for parents who feel isolated [4,7]. Empirically, participation in supportive online communities has been associated with reduced depressive symptoms and increased parenting self-efficacy in some studies [7]. Conversational agents such as Woebot, although not designed specifically for mothers, have shown promising effects in reducing depressive and anxious symptoms in young adults and perinatal populations, suggesting that artificial intelligence (AI)-mediated interaction can play a meaningful role in mental health support [8].

These apparently contradictory findings highlight the inadequacy of simple "screen time" or "digital good versus digital bad" frameworks. If the motherhood constellation is a context-sensitive organization of psychic life, then the introduction of smartphones, social platforms, and AI systems into maternal environments constitutes a structural perturbation. Technologies now enter all 3 discourses of the constellation as quasi-others that speak, respond, withhold, and curate. This study addresses three questions: how smartphones and AI function as actors within Stern's framework; through what mechanisms they influence maternal-infant coregulation, reflective functioning, and support matrices; and under which conditions they support or compromise the adaptive functions of the motherhood constellation.

We argue that digital technologies neither simply enhance nor straightforwardly disrupt motherhood. Instead, they participate in a technologically mediated motherhood constellation whose emergent properties depend on patterns of use, design features, maternal and infant characteristics, and socio-structural factors. This holistic framing aims to provide more than a mere theoretical update; it serves a crucial pragmatic purpose for both research and clinical practice. By identifying smartphones and AI as active "systemic actors" rather than neutral tools, we offer clinicians a more nuanced vocabulary to assess digital "technoference" not as a simple behavioral habit, but as a structural shift in maternal psychic organization. This perspective allows for the development of targeted interventions that address how digital interactions may either bolster maternal self-efficacy or, conversely, fragment the primary relatedness essential for infant development. Ultimately, the "technologically mediated motherhood constellation" provides a roadmap for navigating the complexities of modern parenting in an era where the "support matrix" is increasingly digital.

Theoretical Framework

Core Concepts of the Motherhood Constellation

The Stern motherhood constellation refers to a temporally bounded but developmentally consequential psychic organization that becomes dominant during pregnancy and the first years of the child's life [1]. Its thematic focus on life and growth—ensuring that the infant survives and thrives—is accompanied by an equally intense concern with establishing a primary relationship that feels emotionally alive and mutually responsive. Simultaneously, the mother must secure a supporting matrix that can carry her in the new role and reorganize her identity so that "mother" becomes integrated rather than dissociated or alien. These concerns permeate perception, fantasy, and action.

The 3 discourses through which these themes are elaborated are central. In the discourse of the mother with her own mother, transgenerational narratives, identifications, and conflicts are revisited and renegotiated. In the discourse of the mother with herself-as-mother, she evaluates, justifies, and sometimes critiques her caregiving self, using cultural and familial ideals as standards. In the discourse of the mother with the infant, she engages in concrete, embodied interaction whose microregulation feeds back into the other 2 discourses [1]. This triadic architecture makes the constellation inherently relational and context-embedded. The Stern framework was derived from a synthesis of longitudinal infant observations and extensive clinical interviews with parents in psychotherapy, rather than controlled laboratory experimentation. This approach allowed him to capture the subjective, phenomenological "internal world" of the parent during this transition. However, since its publication, the theory has been subject to various revisions. Critics have pointed out its traditional focus on the nuclear family, which may not fully represent the diversity of modern parenting structures (eg, single, same-sex, or adoptive parents). Furthermore, while Stern emphasized the "support matrix" as a physical and relational network, contemporary scholars argue that his model can at times overidealize maternal attunement, potentially neglecting the socioeconomic and structural stressors that modern parents face [9].

XSL•FO
RenderX

Dyadic Regulation, Attachment, and Reflective Functioning

Work on dyadic regulation and attachment clarifies why disruptions in maternal attention may have outsized developmental consequences. The mutual regulation model developed by Tronick and Beeghly [10] conceptualizes infant–caregiver interaction as a process in which both partners attempt to coordinate states, inevitably failing at times but ideally repairing mismatches. Successful repair, rather than perfect synchrony, supports the infant's sense of efficacy and trust. Ainsworth's concept of maternal sensitivity—the capacity to perceive, interpret, and respond appropriately to infant signals—emerged as a robust predictor of attachment security in her classic Baltimore studies [11]. The attachment theory by Bowlby [12] cast these patterns in a developmental perspective, emphasizing how early experiences of caregiver availability are internalized as working models of self and other.

Mentalization theory adds a further layer by highlighting the importance of the caregiver's capacity to see the child as a psychological agent. Fonagy and Target [13] introduced parental reflective functioning as a construct that captures how parents understand and talk about their child's mind and their own. Later work has shown that higher reflective functioning is associated with more sensitive caregiving and more secure attachment, even under stress [14]. Reflective functioning also shapes how parents use and interpret external advice and support.

Digital technologies intersect with these mechanisms in several ways. Smartphones compete with infant cues for attentional resources, often via deliberately salient notification systems [5,15]. They provide alternative routes for affect regulation, including distraction and remote social contact, which may either support or displace dyadic coregulation. They offer additional "voices"—online communities, influencers, and AI systems—that comment on maternal practices and infant states, thereby entering into the discourse of the mother with herself-as-mother and with her own mother. Understanding maternal-technology relations, therefore, requires situating them within this regulatory and reflective architecture. For instance, AI-driven chatbots, such as Woebot, are increasingly used by women during the perinatal period to monitor mood symptoms and obtain immediate cognitive-behavioral support [8]. These tools effectively act as digital "auxiliary" supports within the maternal psychic space, providing a 24/7 interactive presence that complements the traditional matrix of support, yet also introduces new dynamics of technological mediation in the mother-infant bond.

Technology as a Systemic Actor: Ecological and Sociotechnical Perspectives

To conceptualize smartphones and AI as actors in the motherhood constellation, we draw on ecological systems theory and actor–network theory. Bronfenbrenner's [16] ecological model describes development as being shaped by nested systems, ranging from the immediate microsystem of face-to-face interactions to the macrosystem of culture and institutions [17]. Digital platforms complicate this stratification. A smartphone is present in the microsystem—literally on the sofa where the mother and infant interact—yet it is also an exosystemic conduit for work demands, news, and distant relationships, as well as a macrosystemic embodiment of economic and cultural logics.

Actor–network theory, particularly Latour's [15] work, emphasizes that nonhuman entities such as technologies participate in networks of action through their material properties and designed affordances. Smartphones prompt checking through push notifications, haptic feedback, and interface designs optimized for engagement. Social media platforms algorithmically curate content, promoting certain narratives of "good motherhood" while occluding others. AI systems generate text that appears conversationally responsive and emotionally attuned, even when it is based on statistical patterning rather than genuine understanding. These features shape human behavior without determining it.

In this paper, smartphones and AI are treated as systemic actors whose affordances, constraints, and algorithmic architectures coconstitute the motherhood constellation. They do so by capturing and fragmenting attention, structuring access to information, shaping perceived norms through algorithmic curation, and providing new forms of quasi-relational responsiveness. The question is not whether mothers "use" technology but how these actors participate in and modify the 3 discourses and 4 themes of the Stern framework.

Technoference as a Mechanism of Disruption

The construct of "technoference," developed by McDaniel and Radesky [5], captures everyday intrusions of digital devices into family interactions. In their longitudinal study of parents of young children, higher levels of perceived technoference—defined as technology-based interruptions during parent–child activities—were associated with more externalizing and internalizing problems in children, with parenting stress mediating part of this association [5]. This work extends earlier cross-sectional findings linking problematic parent technology use to less responsive parenting and more child behavior problems.

Experimental studies adapt the still-face paradigm to smartphones. Myruski et al [6] asked mothers to interact naturally with their infants, then to engage with their phones for a short period, and then to reengage. Infants exhibited increased negative affect, decreased gaze toward their mothers, and elevated attempts to reestablish interaction during the phone phase, followed by incomplete recovery in the reunion phase [6]. Systematic reviews, including those by Kildare and Middlemiss [18] and by Braune-Krickau et al [19], synthesize accumulating evidence that parental mobile device use is associated with reduced responsiveness, increased child bids for attention, and more conflict around device management [8].

From a motherhood constellation perspective, technoference can be conceptualized as a recurrent perturbation of the discourse between a mother and her infant. The smartphone becomes a third presence in the dyadic field, sometimes silent, sometimes loudly calling the mother away. Its interruptions are not neutral; they are structured by work demands, social expectations of constant availability, and persuasive design

XSL•FO
RenderX

features. These microruptures in mutual regulation do not necessarily produce pathology, but they may accumulate in ways that shape an infant's expectations of caregiver availability and a mother's self-representations as "distracted" or "failing."

Technology as an Actor in the Parenthood Constellation: Empirical Evidence

This section revisits the 4 thematic concerns by Stern—life growth, primary relating, matrix of support, and identity reorganization—in light of empirical work on digital media, smartphones, and AI in maternal contexts.

Life Growth and Digital Information Seeking

Within the life-growth theme, perhaps the most visible transformation concerns how mothers access and evaluate knowledge about infant health and development. Lupton's [3] focus-group study with Australian mothers documented that digital media were experienced as central, sometimes indispensable, sources of information during pregnancy and early motherhood. Participants described using websites, apps, blogs, forums, and social media to understand bodily changes, interpret infant behavior, and manage anxiety, often multiple times per day [4]. They valued immediacy, anonymity, and the ability to triangulate among different sources.

An earlier work by Madge and O'Connor [7] on "parenting gone wired" similarly depicted the internet as a vital site of empowerment for new mothers, providing alternative information channels and virtual companionship during isolated periods. Mothers reported that online forums and email lists were often more responsive and less judgmental than offline supports, especially when discussing taboo topics such as regret, sexual difficulties, or ambivalence.

At the same time, research has identified an information-abundance paradox. High-frequency online searching about health has been associated with heightened health anxiety and "cyberchondria," as described by Starcevic and Berle [20]. In maternal samples, intensive online information seeking has been linked to increased worry, decision paralysis, and diminished confidence when digital sources offer contradictory or alarmist content [21]. Algorithmic curation can amplify such effects by preferentially surfacing engaging, emotionally charged posts, including extreme narratives about risk and harm [22].

Conversational AI complicates the life-growth landscape further. The randomized controlled trial of the Woebot chatbot by Fitzpatrick et al [8] demonstrated that young adults with depressive symptoms who interacted with the AI for 2 weeks showed significantly greater reductions in depression scores than controls, illustrating the feasibility of fully automated conversational cognitive-behavioral therapy. Although not perinatal-specific, such work has inspired perinatal chatbots that offer psychoeducation, symptom monitoring, and problem-solving strategies to pregnant and postpartum women. Early evaluations suggest high acceptability, with mothers valuing 24/7 availability, nonjudgmental tone, and rapid feedback when they fear something is wrong but feel reluctant to "bother" professionals [23].

From a motherhood constellation perspective, these digital and AI systems enter the life-growth discourse as additional "experts" and "consultants." They coexist with pediatricians, midwives, grandmothers, friends, and manuals, but their temporal characteristics—constant availability, instant response—and discursive style—concise, often prescriptive, sometimes algorithmically optimized for engagement—make them uniquely salient. Some mothers report feeling reassured when digital advice confirms their intuition; others feel increasingly dependent on constant checking, with uncertainty escalating rather than diminishing.

The transgenerational discourse is also affected. Ethnographic and interview studies suggest that mothers use online information both to challenge and to supplement family advice. Some describe the internet as a way to "fact-check" their own mothers and forge more autonomous caregiving identities, while others report that turning first to digital sources has weakened intergenerational conversations, especially when relationships are conflictual or geographically distant [7,24]. Transgenerational knowledge thus becomes one voice among many in a crowded informational field.

Primary Relating and Interactional Quality

The primary related theme focuses on the establishment of an emotionally attuned, mutually regulated relationship between a mother and her infant. Within this domain, technoference research directly implicates smartphones as actors in the dyadic field. McDaniel and Radesky's [5] concept of technoference highlights that seemingly minor, everyday technology interruptions during shared family activities are associated with more problematic child behavior. Their longitudinal work showed bidirectional links: parental technology use predicted later child externalizing behavior, and child behavior predicted later increases in technoference, partly via parenting stress [5].

The adaptation of the still-face paradigm to mobile devices by Myruski et al [6] provided an experimental analog. When mothers were instructed to attend to their phones for a brief period during interaction, infants responded with increased negative affect, protests, and attempts to regain attention, and they showed incomplete recovery after the mothers put the phones away [6]. The authors interpret these findings as evidence that device-induced caregiver unavailability may be experienced by infants as a kind of "digital still face."

Systematic reviews by Kildare and Middlemiss [18], as well as by Braune-Krickau et al [19], converge on the conclusion that parental device use is associated with reduced sensitivity, less verbal and nonverbal engagement, and more conflict around attention and devices [8,19]. A broader review of parental smartphone use and parent-child interactions describes how enhanced connectivity can distract parents from supervising and engaging with children, leading children to engage in risky or disruptive behaviors to recapture attention [8,25].

At the same time, mothers often experience smartphones as essential tools for their own emotional survival. Qualitative studies highlight that many women use phones during feeding,

XSL•FO
RenderX

rocking, or contact naps to alleviate boredom, maintain their adult identity, seek support, or distract themselves from intrusive worries [4]. Some report that brief digital "time-outs" make it easier to regulate their own affect and return to the infant with more patience. This suggests that digital tools may support maternal regulation in ways that indirectly benefit the dyad, especially when offline support is sparse.

A more concerning pattern arises when screens are routinely used to regulate infant distress. Radesky et al [26] have described how parents increasingly rely on mobile devices to calm upset children, particularly in public settings or during family stress. Longitudinal work suggests that high reliance on screens for emotion regulation may be associated with slower development of self-regulatory skills and more behavioral difficulties, though causality is difficult to establish [26]. In the terms described by Stern, digital devices may come to occupy positions in the coregulatory system that would otherwise be filled by the caregiver's face, voice, and body.

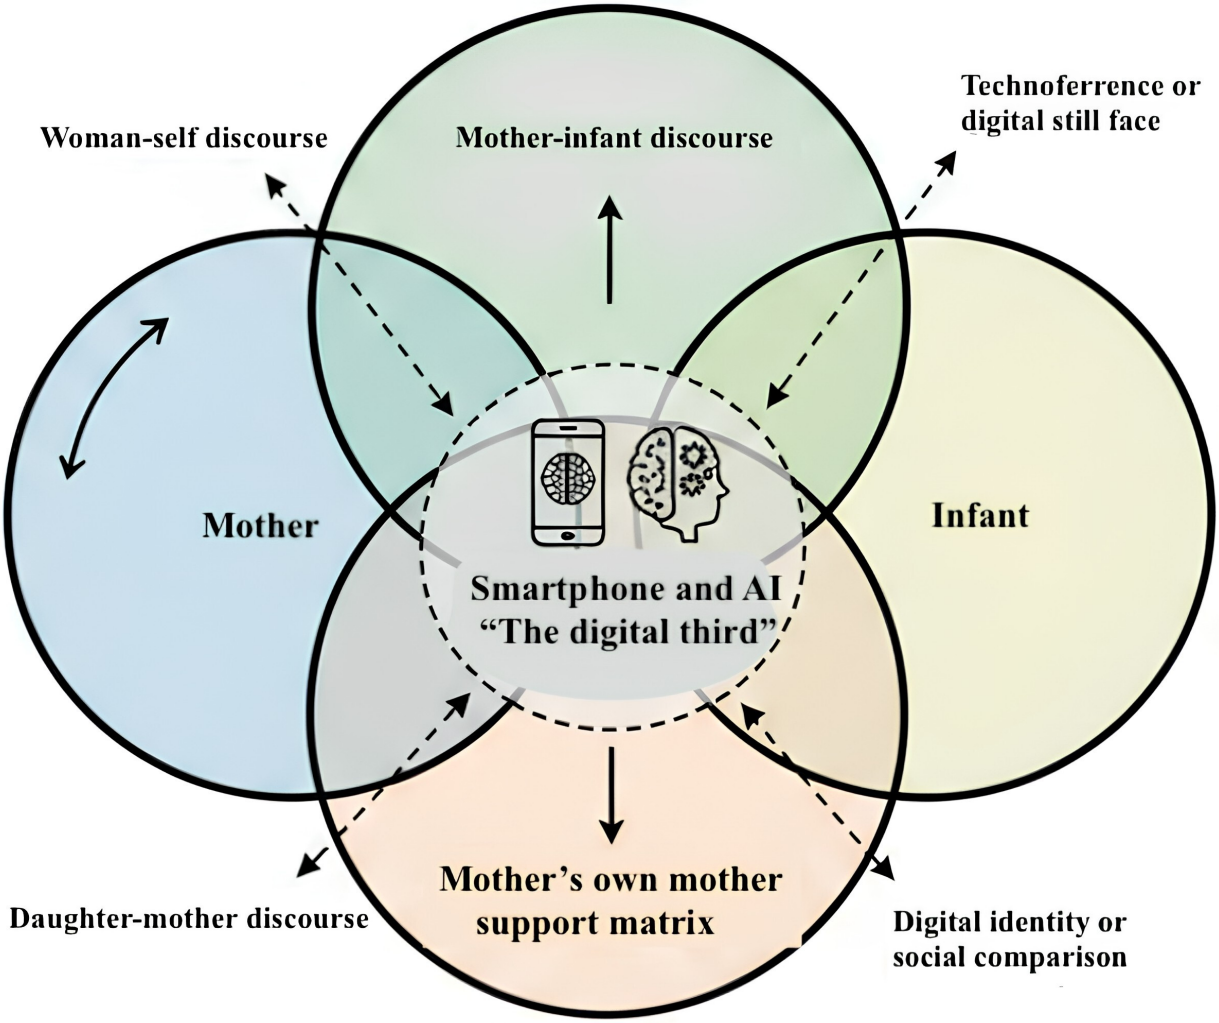
A more optimistic strand of research documents how digital media can enhance primary relationships when used intentionally. Video calling enables ongoing contact between infants and distant relatives; infants quickly learn to respond to familiar faces on screen, and such interactions can sustain relationships that might otherwise deteriorate [27]. Apps explicitly designed to support sensitive parenting—for example, by prompting parents to observe and respond to infants' cues or by suggesting developmentally appropriate play—have shown preliminary promise in increasing parental confidence and observed sensitivity in small trials [23]. In these designs, digital tools are explicitly oriented toward supporting, rather than competing with, mutual regulation.

Matrix of Support in Digital Contexts

The Stern matrix of support encompasses the interpersonal and institutional resources that sustain the mother in her caregiving role [1]. Digital technologies have become deeply woven into this matrix. The study by Madge and O'Connor [7] on online mothering forums demonstrates that the internet functions as an "intimate public" in which mothers share experiences, seek advice, and normalize distress. Participants describe online communities as accessible, flexible, and less judgmental than offline spaces, particularly for sensitive topics.

Lupton's research similarly shows that mothers value online groups and social media for the sense of being "in it together," especially when facing sleep deprivation, loneliness, and contradictory professional advice [3]. These digital communities provide not only informational support but also emotional and identity-related support, with mothers describing experiences of recognition and validation when others articulate similar struggles.

Quantitative research on online peer support for perinatal mental health suggests that participation in moderated, supportive communities can be associated with reduced depressive symptoms and an enhanced sense of competence, though effect sizes are modest and heterogeneity is high [7]. However, passive browsing without interaction appears to be more strongly associated with social comparison and distress [28].



Here, the digital support paradox becomes evident. The same platforms that offer connection also expose mothers to highly curated representations of motherhood. Research on social media and body image has shown that exposure to idealized online images is associated with increased appearance dissatisfaction via social comparison processes [29]. Similar mechanisms likely operate in maternal domains. Studies of "sharenting" and maternal social media use report that mothers often feel pressure to present an image of "good mothering" on platforms like Facebook and Instagram, even when this feels discordant with their lived experience [30,31]. Such pressures can intensify guilt, shame, and self-criticism, especially among mothers who are already vulnerable to depression or anxiety.

The Algorithmic Matrix of Support: A Structural Reconfiguration

In the original framework by Stern, the "matrix of support" is not merely a logistical network but a psychic envelope—akin to Winnicott's "holding environment" [32]—that shields the mother, allowing her to safely undergo the regression necessary to identify with her infant. We contend that the integration of smartphones and AI induces a structural reconfiguration of this matrix, evolving it from an exclusively human-centric system into a hybrid, algorithmic matrix (Figure 1). In this mediated constellation, technology acts as a digital transformational object that reshapes the maternal experience through several complex mechanisms.

XSL•FO
RenderX

Figure 1. The technologically mediated motherhood constellation framework. AI: artificial intelligence.

The first mechanism concerns the externalization of reflective functioning, as the use of virtual assistants and data-tracking apps shifts the process of meaning-making from an internal, intersubjective space to an external, objective one (as illustrated in the central node of Figure 1). While Stern described a mother learning to interpret her infant's cues through intuitive attunement, contemporary mothers often mediate this interpretation through algorithmic outputs. This suggests a risk of dementalization, where numerical data may supersede affective synchrony, transforming the matrix from an emotional container into a technical service provider.

Furthermore, the emergence of the so-called "digital third" causes a disruption of generational linearity, where the support matrix traditionally operated along a mother–own-mother axis, facilitating the transmission of transgenerational wisdom. The contemporary mother frequently experiences tension between the embodied, lived knowledge of her own mother and the optimized knowledge provided by algorithms. This conflict can weaken the daughter-mother discourse, resulting in a support matrix that is highly efficient in information delivery but potentially impoverished in terms of narcissistic support and relational warmth.

Finally, unlike the human matrix, AI is devoid of its own needs and never sleeps, creating an illusion of infinite availability. This hyperavailability induces a distortion in maternal psychic time, potentially bypassing the necessary frustrations and waiting periods that foster resilience. There is a concrete risk that algorithmic support functions as a psychic prosthesis which, while providing immediate anxiety relief, may interfere with the gradual consolidation of an autonomous maternal identity (Figure 1).

AI systems have begun to occupy positions within the support matrix as quasi-relational resources. Mothers using perinatal chatbots report feeling "heard" and "accompanied" during solitary night-time feeds, framing the AI as a safe, always-available listener for worries they might hesitate to share with others [23]. More broadly, work on digital mental health interventions suggests that users can develop attachment-like feelings toward AI "therapists," experiencing them as supportive companions [33]. In contexts of limited human support, AI may become a primary interlocutor, raising questions about substitution versus supplementation of human relationships.

Digital support is unequally distributed. Research on digital inequalities shows that low-income and marginalized families often have less reliable internet access, lower-quality devices, and fewer digital literacy resources, which limits their ability to benefit from online communities and health information [34]. Within mainstream parenting spaces, mothers of color and other

XSL•FO
RenderX

marginalized groups report experiencing racism, classism, and judgment, which leads some to withdraw or create alternative, more inclusive subcommunities [35]. Thus, while digital platforms can expand the matrix of support, they can also reproduce and intensify existing inequities.

Identity Reorganization in the Age of Sharenting and Metrics

The identity reorganization theme concerns the integration of the maternal role into the self. Digital practices such as sharenting and online self-presentation are now central to this process. Blum-Ross and Livingstone's [30] analysis of "sharenting" describes how parents share stories and images of their children as part of crafting a digital self that is deeply relational and family-centered. A study by Kumar and Schoenebeck [31] of new mothers on Facebook similarly showed that posting baby photos functions as a "modern day baby book," a way of enacting and receiving validation for "good mothering."

These practices can support identity consolidation by providing external recognition and by enabling parents to narrate their experiences. They also create opportunities to challenge restrictive norms by sharing "honest" accounts of difficulty and ambivalence. Yet, they also generate tensions. Some parents experience a gap between the polished maternal persona they feel expected to perform online and the messy, ambivalent reality of their daily lives, leading to feelings of inauthenticity and self-doubt [31]. For others, metrics such as likes, comments, and shares become subtle but powerful validators of maternal adequacy.

Algorithmic curation shapes which maternal identities are most visible. Analyses of influencer culture suggest that high-visibility maternal personas often embody intensive parenting ideals, combining constant child-centeredness with aestheticized domesticity and entrepreneurial self-branding [36]. For parents who do not fit these templates—because of class, race, disability, family structure, or parenting style—digital landscapes can amplify a sense of being "out of place." Conversely, some parents find in niche online communities, models of motherhood that align more closely with their values, such as queer parenting networks, disability parenting accounts, or antiracist parenting spaces, thereby expanding the repertoire of possible parental selves.

In the terms described by Stern, the discourse of the mother with herself-as-mother is now partially externalized into digital traces that are archived, searchable, and represented via "memories" and recommendation systems. The maternal self becomes a datafied object, visible to others and to future versions of the self. This raises new questions about how the continuity of identity is negotiated when one's earlier maternal posts resurface years later, sometimes in altered relational contexts.

Toward a Technologically Mediated Motherhood Constellation

The empirical material reviewed above suggests that the Stern motherhood constellation remains a valuable organizing framework but requires systematic updating for digital contexts. Rather than proposing an entirely new model, we suggest that smartphones and AI are best conceptualized as additional actors within the existing architecture, giving rise to a technologically mediated motherhood constellation.

A central question in this reconfiguration concerns the place of the father and the broader paternal function. In the Stern original formulation, the father appears primarily as part of the supporting matrix rather than as a central organizer of the constellation [1]. By contrast, psychoanalytic and developmental work since Winnicott [32,37] has conceptualized the paternal function as a crucial "third" that interrupts the mother–infant dyad, limits omnipotence, and introduces the child into a shared reality structured by difference, law, and time. Winnicott's [32,37] account of the transition from subjective omnipotence to objective reality hinges on the infant's progressive discovery that the mother is not fully under their control, and that there are other relationships and demands that claim her attention, a process that is often mediated by the father or paternal figures. Later authors have elaborated on this notion of thirdness: Ogden's [38] "analytic third" describes a jointly created psychic field that is neither reducible to 1 partner nor the other; Britton's [39] work on the parental couple emphasizes that recognizing the parents' relationship to one another is a developmental achievement that requires relinquishing fantasies of exclusive possession and accepting the limits imposed by an already-existing adult couple. Feldman's [40] research on triadic synchrony similarly suggests that coordinated patterns of interaction among mother, father, and infant are associated with better socioemotional outcomes, with each caregiver contributing distinct but complementary regulatory inputs. Epidemiological work on paternal perinatal depression underscores that fathers' psychological functioning is not peripheral; rates of paternal depression in the perinatal period are substantial, and paternal symptoms are correlated with maternal depression and child outcomes [41,42]. Within a technologically mediated constellation, the position of this human third is increasingly shared with, and sometimes displaced by, digital actors. In many families, the everyday triad becomes mother-infant-smartphone, with the device occupying the position of the salient "other" that draws maternal attention away. Crucially, however, the device does not perform the structuring functions of the paternal third. It rarely introduces meaningful, tolerable frustration; instead, it offers a fantasy of limitlessness—endless information, on-demand soothing, perpetual availability—that may collude with omnipotent wishes in both mother and child. Rather than anchoring the dyad in a wider symbolic order, technology frequently presents itself as an extension of individual will and desire. The risk is that digital actors simulate thirdness by inserting themselves into the relational field without providing the kind of containing, law-bearing, reality-introducing presence that human others can offer. When fathers are physically or psychologically present

XSL•FO
RenderX

and engaged, they can mediate and modulate digital influences, participating in the coconstruction of rules and boundaries around technology use. When they are absent, overwhelmed, or themselves absorbed in digital environments, the mother-infant dyad may be left to negotiate an asymmetrical relationship with powerful technological actors without the support of a robust human third [40-42]. The technologically mediated motherhood constellation must therefore be conceptualized not only as mother–infant–technology, but as embedded in a wider field that includes, or fails to include, paternal and other third functions.

Within this reconfigured constellation, the discourse between a mother and her own mother is increasingly conducted via digital channels. Messaging apps, video calls, and family group chats enable frequent, sometimes intense contact despite geographic distance. Grandmothers can "be present" at feeding, bathing, or milestones via live video, contributing advice and commentary in real time. At the same time, their authority is subtly relativized as mothers can instantly consult alternative digital sources. The grandmother's voice becomes one among many, strengthened by digital connection yet challenged by online communities and AI-generated expertise.

The discourse of the mother with herself-as-mother is deeply permeated by algorithmic input. Reflection on one's adequacy, values, and desires is no longer carried out solely in inner dialogue or in the consulting room, but in interaction with feeds that display other mothers, with notifications that solicit engagement, and with AI systems that provide interpretations and reassurance. The internal critic may be amplified by exposure to idealized images; the internally may be supported by online solidarity and by digital tools that normalize difficulty. For some mothers, conversing with AI systems may function as a form of guided self-reflection; for others, it may externalize and potentially displace their own reflective capacities.

The discourse between mother and infant is altered both directly by technoference and indirectly by the ways digital actors modulate maternal mood, knowledge, and expectations. The smartphone is often physically present in the triad of mother-infant-device; its potential to interrupt is built into its design. Yet, digital tools can also decrease maternal anxiety by providing quick access to trustworthy information or by connecting mothers to supportive communities, thereby freeing attentional and emotional resources for the infant. The same device that disrupts attunement in one context may enable it in another.

These dynamics suggest that the impact of technology on the motherhood constellation is neither uniformly beneficial nor uniformly detrimental. It is better conceptualized as distributed along a spectrum. At one pole lies a technology-enhanced constellation, in which digital actors expand the support matrix, provide reliable information, reduce isolation, and are used in ways that respect and protect the primacy of the mother–infant relationship. In the middle lies a technology-neutral constellation, in which digital tools are present but do not significantly alter core relational processes. At the other pole lies a technology-disrupted constellation, characterized by compulsive use, pervasive technoference, overreliance on digital regulation for both the mother and the infant, and heightened self-criticism driven by social comparison.

Movement along this spectrum is not fixed; mothers may oscillate between more and less adaptive patterns across days, developmental stages, and life events. Crucially, positioning on this spectrum is not solely an individual choice; it is shaped by structural factors such as work demands, availability of offline support, economic pressures, and the business models of platform providers. Recognizing the technologically mediated constellation as a systemic phenomenon rather than an individual failing is essential for ethical responses.

Clinical and Research Implications

Clinical Assessment and Intervention

For clinicians working in perinatal mental health and parent-infant psychotherapy, digital technologies have become integral to the ecology of caregiving. Assessment should, therefore, routinely include exploration of maternal technology use. Rather than quantifying "screen time," the focus should be on patterns, meanings, and contexts: when and why mothers reach for their phones, how they feel before and after digital engagement, what functions different apps serve, and how they experience the impact of technology on their relationship with the infant [43].

Video-based interventions offer a promising route. When mothers and clinicians watch recordings of everyday interactions together, moments of technoference can be observed and reflected upon: a notification that pulls attention away from the infant, a momentary shift in the infant's affect as gaze is withdrawn, or a tension between the perceived urgency of a message and the infant's bid for contact. These microevents can serve as starting points for exploring underlying needs, such as the mother's desire for adult contact, fear of missing work communications, or use of digital distraction to manage anxiety or boredom.

Interventions should avoid moralizing or prescribing blanket digital abstinence. Given that many mothers use digital tools to access support they might otherwise lack, pathologizing technology use risks compounding guilt. Instead, clinicians can collaborate with mothers to develop realistic "micro-boundaries"—for example, device-free feeding routines where possible; silencing nonurgent notifications during certain caregiving windows; or setting aside dedicated times for online support that do not compete with infant cues. Psychoeducation about infants' needs for contingent responsiveness, the mechanisms of technoference, and the paradoxes of online information can support more intentional use [44].

It is equally important to address the broader support matrix. When digital tools compensate for structural deficits—such as the absence of partner support, lack of paid leave, or limited access to professional care—interventions should validate these realities rather than individualize blame. Clinicians can help mothers identify and mobilize additional offline supports where feasible, and advocate at service and policy levels for conditions that reduce forced overreliance on digital actors [45].

XSL•FO
RenderX

Research Priorities

Several research priorities emerge from this conceptualization. First, longitudinal studies are needed to examine how early maternal technology patterns relate to longer-term outcomes in attachment, child regulation, and maternal mental health, with attention to bidirectional processes. Most existing work is cross-sectional or short-term experimental; developmental trajectories remain under-specified.

Second, intervention research should move beyond screen-time reduction to test programs aimed at reshaping mothers' relationships with digital tools. Mentalization-based interventions that include explicit reflection on technology use, design-informed interventions that leverage apps to scaffold attunement rather than distraction, and community-based interventions that build hybrid online-offline support networks are all promising candidates.

Third, AI-specific research is urgently required. We know little about how mothers use general-purpose chatbots for parenting, how they experience AI-mediated support, and what meanings they attribute to these interactions. Mixed-methods studies could explore whether AI support functions as a gateway to human help-seeking or as a substitute for it, and how it influences the discourses of the constellation.

Fourth, moderator research should systematically examine how reflective functioning, attachment history, psychopathology, socioeconomic status, culture, and child temperament shape the impact of digital engagement. Cross-cultural comparative work is essential, as motherhood norms and digital infrastructures differ markedly across societies. Finally, collaboration with human-computer interaction and design researchers is needed to develop and evaluate "benevolent" technologies intentionally designed to support maternal-infant relationships rather than merely to maximize engagement.

Policy and Design Considerations

Recognizing smartphones and AI as actors in the motherhood constellation has implications for technology design and policy. At the platform level, features that limit intrusive notifications during likely caregiving times, prioritize credible health information, discourage infinite scrolling, and offer clear controls over data collection could meaningfully reduce technoference and anxiety without relying solely on individual self-control [28,46]. Parenting apps and perinatal chatbots should be developed in partnership with clinicians, researchers, and diverse groups of mothers, with explicit attention to safety, equity, cultural relevance, and pathways to human support when needed.

At the policy level, it is crucial to resist framing digital interventions as substitutes for structural support. No chatbot can compensate for the absence of paid parental leave, accessible childcare, or comprehensive perinatal mental health services. Overreliance on technological fixes risks shifting responsibility for coping with structurally generated stress onto individual mothers, exacerbating inequalities. Policies that strengthen the offline matrix of support—economic security, family-friendly work conditions, and equitable health care access—are foundational for any healthy technologically mediated constellation.

Ethical guidelines for AI in health care should be applied rigorously to perinatal applications. These include transparency about AI limitations, clear labeling of AI-generated content, robust data protection, and mechanisms for human oversight and escalation. Given the vulnerability of many mothers during the perinatal period, the commercial exploitation of anxieties through targeted advertising or persuasive design warrants particular scrutiny.

Limitations and Conclusions

This theoretical synthesis is subject to several limitations. The technological landscape is changing rapidly; platforms and AI capabilities evolve faster than empirical research can track. Some of the specific configurations described here may soon be supplanted by new forms of digital engagement. The empirical literature is heavily skewed toward Western, educated, urban samples; the technologically mediated constellation may look quite different in contexts with different kinship structures, caregiving norms, and digital infrastructures. Many studies rely on self-reported technology use and parenting behavior, which are prone to bias; more work using passive sensing, observational methods, and multiinformant designs is needed. Causal inference remains challenging; children's behavior influences parental technology use, and maternal mental health both shapes and is shaped by digital engagement.

Moreover, "technology" is not a single entity. Aggregating across platforms, devices, and uses risks obscuring critical differences between, for example, doom-scrolling news during night feeds, participating in a moderated peer-support group, and using a clinically designed app. Future research and theory should differentiate clearly among these modalities and attend to their specific relational affordances.

Despite these limitations, the Stern motherhood constellation remains a powerful lens for understanding early motherhood in digital societies. Conceptualizing smartphones and AI as systemic actors within this constellation clarifies how they participate in the 3 discourses and 4 themes that organize maternal experience. Digital actors expand access to information and support, create new spaces for connection and identity work, and provide tools for emotion regulation. They also fragment attention, introduce new forms of technoference, amplify social comparison, and can displace or distort intergenerational and local sources of knowledge.

The question is not whether mothers should use technology—for most, this is neither realistic nor desirable—but how digital actors can be integrated in ways that support, rather than undermine, life growth, primary relating, the matrix of support, and identity reorganization. This requires interventions at multiple levels: supporting mothers' reflective and intentional use; designing technologies that respect, rather than exploit, the vulnerabilities of the perinatal period; and addressing structural conditions that currently force many mothers to rely on digital scaffolding in the absence of adequate offline support.

XSL•FO
RenderX

The technologically mediated motherhood constellation is already a reality. The task for clinicians, researchers, designers, and policymakers is to understand its dynamics and shape environments in which digital actors become allies, rather than adversaries, of the maternal and infant needs at its core.

Acknowledgments

During the preparation of this paper, the authors used ChatGPT 5.0 to enhance linguistic clarity, readability, rectify grammatical errors, and refine academic expressions in non-native English sections of the manuscript. The artificial intelligence–generated suggestions were meticulously reviewed, modified, and validated by the authors to ensure adherence to scholarly standards. Abstract

Background: Despite the benefits of the Special Supplemental Nutrition Program for Women, Infants, and Children (WIC), many eligible children remain unenrolled.

Objective: This study evaluated responses to an electronic health record (EHR)–embedded federal nutrition program (FNP) participation screening and WIC referral tool implemented within 8 clinics during well-child visits for children younger than 5 years of age.

Methods: Structured EHR data from July 2020 to October 2023 were extracted to summarize screening, referral acceptance, WIC enrollment outcomes, and patient demographics. Multivariable logistic regression was used to examine patient-level predictors of WIC nonenrollment at the first screening, referral acceptance, and enrollment among those accepting a referral, with analyses stratified by clinic type.

Results: Among 5385 children, 51.8% (n=2785) were newborn-aged, 36.6% (n=1969) were Hispanic, and 87.8% (n=4726) were Medicaid-insured. The mean age at the initial screening was 10.7 (SD 14.2) months. Among screened patients (n=3606), 34% (n=1235) were not enrolled in WIC at the first screening. Medicaid coverage, an academic clinic setting, non-Hispanic Black or Hispanic race, and ethnicity were associated with lower odds of WIC nonenrollment. Among those not enrolled with a documented response to referral (n=819), 59% (n=488) accepted the referral. Acceptance was higher among non-Hispanic Black and Hispanic patients, newborn-aged patients, those with Medicaid coverage, and those seen in academic clinics. Among referral acceptors with follow-up (n=438), 61% (n=265) were enrolled at the last screening, with higher odds among newborn-aged patients and those in academic clinics.

Conclusions: An EHR-based automated intervention can facilitate screening and referral to WIC. WIC participation at the first screening, referral acceptance, and enrollment after referral varied by sociodemographic characteristics, suggesting opportunities to improve equitable access through health care system–based approaches.

KEYWORDS

WIC; food insecurity; electronic health records; referrals; pediatrics

Introduction

The Special Supplemental Nutrition Program for Women, Infants, and Children (WIC) is a federal nutrition program (FNP) that provides access to nutritious foods, nutrition education, lactation support, and health care referrals for eligible low-income pregnant and lactating individuals, as well as infants and children under 5 years of age. Participation in WIC is

XSL•FO
RenderX

associated with numerous health benefits, including improvements in dietary quality and reductions in the risk of prematurity, low birth weight, childhood obesity, and food insecurity [1,2], all of which disproportionately affect racial and ethnic minority populations due to longstanding structural racism [3,4]. Despite these health benefits of WIC participation, many eligible infants and children remain unenrolled.

In 2023, the most recent year in which data are available, only 56% of the eligible 11.8 million women, infants, and children participated in WIC, resulting in benefit underutilization and missed opportunities for improvements in health outcomes [5]. Since 2011, when it peaked at 63%, WIC participation has been declining [6]. Well-documented barriers to participation in WIC include lack of knowledge about WIC or eligibility status, lack of time or transportation to attend in-person visits, cultural and language barriers, negative experiences with WIC clinics, challenges in redeeming benefits, and stigma, among other barriers [7-9]. WIC program flexibilities implemented during the COVID-19 pandemic, such as remote benefit issuance, eased some of the administrative burden of participation and resulted in modest increases in participation [10]. To further expand outreach, increase enrollment in WIC, and ultimately improve health outcomes, cross-sector strategies are necessary [11].

Primary care clinics are uniquely positioned to counsel patients about WIC, facilitate WIC referrals, and encourage enrollment during standard discussions about nutrition at well visits. Providing referrals to WIC in primary care settings represents an evidence-based intervention for reducing food insecurity [12-14]. Several national organizations, including the American Academy of Pediatrics and the Food Research & Action Center, recommend that pediatricians refer patients to WIC [15-17]. Several studies have evaluated care coordination between the health care system and WIC to improve outcomes, such as responsive parenting, and have found that, while few have impacted weight outcomes, integrated services were acceptable among participants [18-21]. However, few have implemented and evaluated WIC participation screening and direct referrals to WIC from the health care system [22-24]. This study evaluated responses to an electronic health record (EHR)–embedded FNP participation screening and WIC referral tool, including screening results, referral acceptance, and WIC enrollment, and examined patient-level correlates and differences by clinic type.

Methods

Study Design and Setting

This retrospective cohort study was part of a mixed methods investigation in which our team expanded an innovative EHR-based FNP participation screening and referral tool. The tool assessed both WIC and the Supplemental Nutrition Assistance Program (SNAP) enrollment and provided WIC referrals at 8 primary care clinics, including 1 academic pediatric clinic, 5 private pediatric clinics, and 2 family medicine clinics, between July 2020 and October 2023. The study took place within Atrium Health Wake Forest Baptist, a large health care system serving a racially and ethnically diverse patient population in the western portion of North Carolina, which uses a fully integrated EHR system (Epic). See McCall et al [24] for a detailed description of the patient demographics of each of these health care clinics. The Wake Forest University School of Medicine Institutional Review Board approved this study.

Electronic Screening and Referrals

Beginning in July 2020, an EHR-embedded tool was implemented during well-child visits at the point of care in one academic clinic, which was a quality improvement project that tested various Plan-Do-Study-Act cycles [22]. Given the success of this project, the tool was expanded in 2021 to 7 other nonacademic clinics, which is the focus of the current study. For the 7 nonacademic clinics, the attending physicians and advanced practice providers exclusively provided care, with patient rooming and screening generally performed by medical assistants (MAs) and other support staff. Within these 7 clinics, considering rooming workflows and the preferences of providers, who did not prefer to have screening embedded in the note template or to perform screening themselves, an automated alert prompted MAs to screen caregivers for FNP participation during the rooming process and to assess family interest in a referral to WIC if not already participating. Given that Medicaid eligibility conferred WIC eligibility, the alert was programmed only to appear for visits with children below 5 years of age who had Medicaid or were uninsured or lived in Forsyth County, North Carolina, the location of our WIC partner. In addition, the alert appeared for those who had not been screened in the prior 6 months and thus did not appear at every visit. The FNP screening question asked: “Does your child currently participate in the WIC or SNAP programs? SNAP is also known as Food Stamps.” Self-reported participation response options of FNP were as follows: WIC only, SNAP only, both WIC/SNAP, neither WIC/SNAP, unsure, or did not ask. For participants who answered the initial FNP screening with the response options of “SNAP only,” “neither,” or “unsure,” an additional automated alert prompted the MA to assess caregiver interest in WIC referral with the following question: “WIC is a free program through the health department that provides food and nutrition support for children from birth through 4 years old. Can we give your information to WIC so they can contact you about enrolling?” Response options were: “Yes, family approves referral for WIC contact” or “No, family does not approve referral for WIC contact.” Prior to activation of the new screening tool within the EHR, research staff visited all clinics in person and conducted hands-on training sessions with clinic staff on how to effectively screen and refer using the tool, as well as how to counsel families. A laminated 1-page job aid was also provided with multiple copies at nursing workstations in each clinic. The job aid included contact information for research team members so that clinic staff or clinic managers could reach out with questions or concerns. Additionally, after the tool was live in the EHR, research staff members followed up regularly through email for 6 months with clinical practice managers to actively ask about any questions or difficulties that staff had encountered with screening.

At the single academic pediatric clinic in our sample, most of the clinical care is provided by residents and advanced practice providers, and the clinical workflows do not typically involve

XSL•FO
RenderX

MAs performing screening duties. At this clinic, WIC screening was operationalized differently to increase screening and referral uptake, with providers (physicians, usually residents) being prompted to screen for FNP participation via an EHR-embedded tool within the well-child visit note template, which has been previously described [22,24]. At the academic clinic, FNP screening was prompted at every well-child visit for children under 5 years because the clinic serves almost exclusively FNP-eligible patients. The same training for the nonacademic clinic was also provided for the academic clinic. In addition, at the start of every new resident block (eg, every 4 wk), providers were given an orientation at morning report, which included how to effectively screen and refer to WIC using the EHR.

For consenting families at all 8 clinics, automated referrals were sent directly to WIC staff via an EHR in-basket message to begin enrollment, as previously described [6,23]. For the study period, structured data were extracted from the pediatric patient's EHR for screening and referral results as well as demographics, including age, race, ethnicity, insurance type, preferred language for health care use, sex, and clinic in which screening occurred. Race, ethnicity, and preferred language for health care use were extracted from self-reported fields within the EHR. Due to missing demographic data, 112 records were excluded for the first screening instance and 94 for the last screening instance.

Study Demographics

Extracted demographics, as noted above, included child age and sex because WIC participation rates vary by age [6], and male sex has been associated with longer WIC participation duration [25]. For age, we categorized pediatric patients as being newborn-aged (≤3 months old) or not (>3 months old), given that the age distribution of the sample was highly concentrated in early infancy and pediatric visit frequency is particularly high during the newborn phase. Race and ethnicity were included because the percentage of the eligible population participating in WIC varies by race and ethnicity, with non-Hispanic Black and Hispanic WIC-eligible individuals more likely to participate in WIC than non-Hispanic White individuals [6]. For analytic purposes, the race and ethnicity categories were Hispanic, non-Hispanic Black, and non-Hispanic White. We included other races and ethnicities in a combined category that included Asian, American Indian/Alaska Native, and Native Hawaiian/Pacific Islander, but we did not interpret them in our results, given small clinic populations of each of these races and ethnicities. Insurance type was categorized as Medicaid or non-Medicaid; non–Medicaid insured patients included those who were uninsured or had commercial or other third-party insurance types. The language preference of the caregiver for health care use, categorized as English, Spanish, or "other," was included because it may be associated with barriers to participation [9,26]. Given the small number of pediatric patients with a primary language other than Spanish or English, we did not interpret the results of the "other" category. Clinic sites were grouped according to the method by which screening took place, such that the 7 clinics using MAs to screen via the automated alert were considered as one category, while one pediatric academic clinic using providers to screen via the note template was considered as a separate category.

Outcomes and Data Analysis

The primary outcomes were (1) likelihood of WIC nonenrollment at the first screening, (2) likelihood of accepting a referral, and (3) likelihood of enrolling in WIC among those accepting a referral. We characterized the initial FNP screening and WIC referral status using the response categories listed above. Among participants for whom the FNP screening was prompted at more than one visit during the study period, we also characterized those who transitioned from reporting no WIC participation (eg, initial screening results of SNAP only, neither WIC/SNAP) to subsequently reporting WIC participation at the final screen as becoming enrolled in WIC. Because follow-up intervals between well-child visits vary, and to allow sufficient time for WIC referrals to potentially result in enrollment, outcomes were defined using the last documented screening encounter during the study period rather than a fixed follow-up window.

Descriptive statistics were used to summarize demographic characteristics and screening and referral responses. Because this study aimed to evaluate and optimize a novel clinical screening and referral process, we used multivariable logistic regression to assess associations with screening and referral outcomes. All models adjusted for child age, sex, race and ethnicity, preferred language, insurance type, year of screening, and clinic type. In analyses of subsequent WIC enrollment at the last screening encounter, we additionally adjusted for days between the first and last screening visits as an adjustment covariate to account for variation in follow-up time and opportunity for enrollment after referral. Because the primary outcome defined WIC enrollment as a receipt of WIC alone or in combination with SNAP, SNAP participation could not be modeled as a separate, mutually exclusive covariate. Models additionally adjusted for the year of the screening encounter to account for temporal trends during the study period. Because the academic clinic implemented screening earlier than the nonacademic clinics and some individual years contained sparse cells for certain outcomes, screening year was categorized into 2 periods (2020‐2021 and 2022‐2023) for regression analyses. We first fit models including clinic type as an independent variable and then conducted stratified analyses by fitting the models separately among patients from academic and nonacademic clinics. In stratified models with sparse cells, when a categorical predictor level had zero outcome events (complete separation), that level was omitted from the model, and comparisons were estimated among remaining levels with observed events. Results are reported as odds ratios (ORs) with 95% CIs. Robust SEs were used to account for potential heteroskedasticity. The results were considered statistically significant at a 2-tailed $P<.05$. Data cleaning and analysis were completed using SAS version 9.4 (SAS Institute, Inc) and Stata version 18.5 (StataCorp).

Ethical Considerations

The Wake Forest University School of Medicine Institutional Review Board approved this study (IRB00078127). As this was a retrospective cohort, EHR-based study, participants' informed consent was waived, and compensation was not provided.

XSL•FO
RenderX

Results

There were 5497 unique records in which the FNP screening prompt appeared at ≥1 visit. Of these, 5385 (98%) records had complete data for all demographic measures of interest and were included in analyses. The mean age of the pediatric patient at the initial screening was 10.7 (SD 14.2; range: 0.03 - 59.2) months, and 51.8% (n=2785) were newborn-aged. Just over half of patients were male (n=2780, 51.6%), 36.6% (n=1969) were Hispanic, 76.4% (n=4113) preferred English for health care use, and 87.8% (n=4726) had Medicaid insurance (Table 1). Few (n=129, 2.4%) reported participation in SNAP only, while 44% (n=2369) were already enrolled in WIC or both WIC and SNAP. Because WIC screening was embedded within the provider note template in the academic clinic, we were unable to determine when screening was prompted but not completed in that setting; therefore, screening completion could only be reliably quantified for the nonacademic clinics, where an automated alert allowed explicit documentation of completed or dismissed screening. Within the nonacademic clinics, 1108 (38%) records completed the screening for WIC participation. Among all patients who were screened (n=3606), 66% (n=2371) reported participation in WIC or both WIC and SNAP at the first screening encounter, while 34% (n=1235) reported no participation in FNP or were unsure. Figure 1 details sample sizes at each step.

Figure 1. Flow of the analytic sample across Special Supplemental Nutrition Program for Women, Infants, and Children (WIC) screening, referral, and enrollment outcomes. WIC enrolled at the last screening at the time of data extraction. FNP: federal nutrition program.

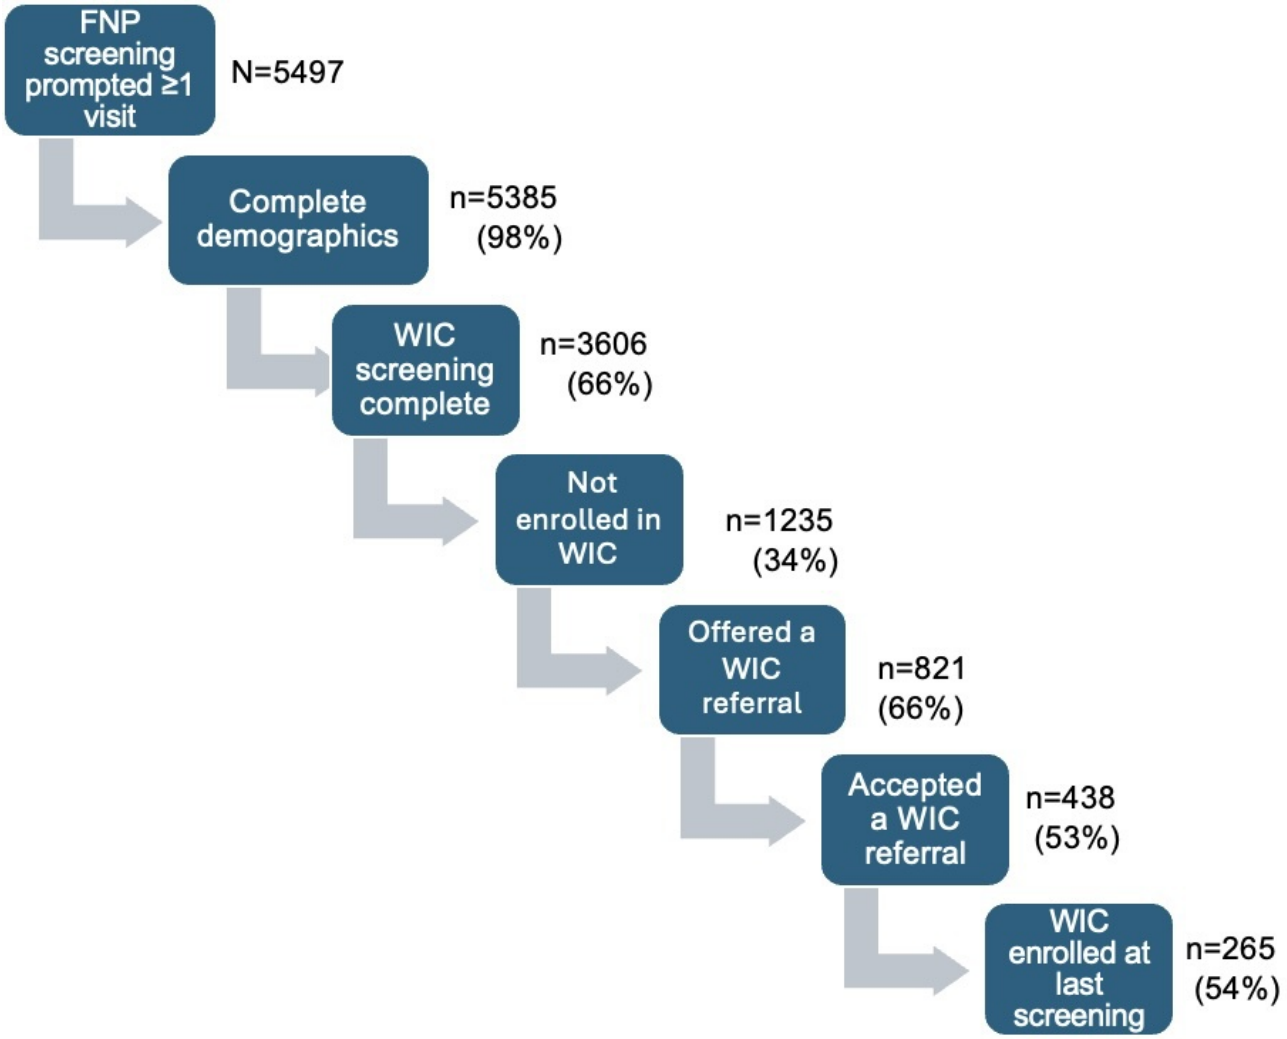

Table 2 presents factors associated with WIC nonenrollment at the first screening encounter; ORs less than 1 indicate lower odds of nonenrollment (ie, greater likelihood of being enrolled in WIC). In the overall model, Medicaid coverage was strongly associated with lower odds of nonenrollment compared with non-Medicaid insurance, and patients attending academic clinics had lower odds of nonenrollment than those seen at nonacademic clinics. Compared with non-Hispanic White patients, non-Hispanic Black and Hispanic patients were also less likely to be unenrolled. Newborn-aged patients had modestly lower odds of nonenrollment relative to older children. In contrast, the odds of WIC nonenrollment increased over time, with higher odds observed in 2022 to 2023 compared with 2020 to 2021. Sex and preferred language were not significantly associated with nonenrollment. Stratified analyses by clinic type demonstrated generally similar patterns, with some attenuation of associations in subgroup models.

[a]Categories for other race and ethnicity and other language were suppressed due to small sample sizes. Models were adjusted for screening year to account for temporal trends during the study period (2020 - 2023).

[b]OR: odds ratio.

[c]These estimates indicate statistical significance at $P<.05$.

[d]Not applicable.

Among participants who were not enrolled in WIC at the first screening encounter (n=1235), 66% (n=815) were offered a referral, and 819 had a documented response regarding referral acceptance. Table 3 presents factors associated with accepting a WIC referral among these patients. In the overall model, non-Hispanic Black and Hispanic patients had higher odds of accepting a referral compared with non-Hispanic White patients. Newborn-aged patients were more likely to accept a referral than older children. Medicaid coverage was associated with substantially higher odds of referral acceptance compared with non-Medicaid insurance. In contrast to patterns observed for nonenrollment, patients seen in academic clinics had higher odds of accepting a referral than those seen in nonacademic clinics. Sex, preferred language, and screening year were not significantly associated with referral acceptance overall. Stratified analyses by clinic type showed generally similar patterns, although CIs widened in subgroup models.

[a]Sample restricted to patients who were screened for WIC participation and had a documented response regarding referral acceptance. Models were adjusted for child age, sex, race and ethnicity, preferred language, insurance type, year of first screening, and clinic type.

[b]OR: odds ratio.

[c]These estimates indicate statistical significance at $P<.05$.

[d]Not applicable.

Among those who accepted a WIC referral and had a documented follow-up response (n=438), 61% (n=265) were enrolled in WIC at the last screening encounter. Table 4 presents factors associated with subsequent WIC enrollment among these participants. In the overall model, newborn-aged patients were more likely to be enrolled in WIC at the last screening compared with older children (OR 6.80, 95% CI 3.89-11.86), and patients seen in academic clinics had higher odds of enrollment than those seen in nonacademic clinics (OR 13.29, 95% CI 4.77-37.02). In clinic-specific analyses, associations were generally consistent in the academic clinics, where newborn age remained associated with enrollment. Estimates for the nonacademic clinics were imprecise because of the smaller sample size and sparse cells; however, Medicaid insurance was associated with lower odds of enrollment compared with non-Medicaid coverage in this subgroup. Race and ethnicity estimates in the nonacademic clinics should be interpreted cautiously, as the non-Hispanic White category was omitted due to zero observed enrollment events, precluding direct comparisons with other groups. Sex, race and ethnicity, preferred language, screening year, and days between the first and last screening visits were not significantly associated with WIC enrollment overall. Due to sparse data in the nonacademic clinics, results should be interpreted with caution.

Table . Multivariable logistic regression of the odds of Special Supplemental Nutrition Program for Women, Infants, and Children (WIC) enrollment at the last screening encounter among patients who were offered a referral with a documented response (N=438)[a].

Patient characteristics	Overall (N=438), OR[b] (95% CI)	Academic clinic (n=384), OR (95% CI)	Nonacademic clinics (n=54)[c], OR (95% CI)
Sex (Ref: female)			
Male	1.04 (0.67-1.64)	0.99 (0.61-1.61)	7.28 (0.55-95.53)
Race and ethnicity (Ref: non-Hispanic White)			
Non–Hispanic Black	1.03 (0.44-2.42)	0.85 (0.31-2.30)	Ref
Hispanic	1.68 (0.71-3.90)	1.28 (0.49-3.37)	1.99 (0.77-5.15)
Newborn (Ref: no)			
Yes	6.80 (3.89-11.86)[d]	7.79 (4.46-13.63)[d]	1.16 (0.20-6.67)
Preferred language (Ref: English)			
Spanish	1.22 (0.67-2.22)	1.31 (0.71-2.46)	0.41 (0.07-2.48)
Insurance (Ref: non-Medicaid)			
Medicaid	1.33 (0.46-3.89)	2.06 (0.71-5.92)	0.06 (0.01-0.72)[d]
Year at the first screening (Ref: 2020 - 2021)			
2022 - 2023	1.17 (0.70-1.97)	1.42 (0.83-2.41)	0.08 (0.00-1.60)
Academic clinic (Ref: no)			
Yes	13.29 (4.77-37.02)[d]	—[e]	—

[a]Multivariable logistic regression adjusted for child age, sex, race and ethnicity, preferred language, insurance type, year of first screening, clinic type, and days between first and last visits; it was not statistically significant and is therefore not shown. Other race and ethnicity and other language categories are suppressed due to small sample sizes.

[b]OR: odds ratio.

[c]In the nonacademic clinic model, the non-Hispanic White category was omitted due to zero observed WIC enrollments. The analytic sample size remained unchanged (n=54).

[d]These estimates indicate statistical significance at $P<.05$.

[e]Not applicable.

Discussion

Principal Findings

Our findings indicate that patient characteristics associated with WIC participation vary across stages of engagement in the WIC referral continuum, including initial enrollment status, referral acceptance, and subsequent enrollment. Consistent with prior literature, we found that non-Hispanic White race, non-Medicaid insurance, and attending a nonacademic clinic were associated with a higher likelihood of not being enrolled in WIC at the first screening encounter. We also observed higher odds of nonenrollment in later years of the study period, which may reflect changes in screening implementation across clinics or broader fluctuations in WIC participation during the COVID-19 pandemic recovery period. Among patients who were not enrolled at the first screening, most accepted a referral when offered, with higher odds of referral acceptance observed among non-Hispanic Black and Hispanic patients, newborn-aged patients, and those with Medicaid insurance. In contrast to patterns observed for nonenrollment, patients seen in academic clinics were more likely to accept a referral and to subsequently enroll in WIC.

These differences may reflect variation in screening workflows and counseling context, as providers in the academic clinic conducted screening directly within the visit note template and may have had more opportunities to discuss WIC benefits with caregivers. Among those who accepted a referral and had a documented follow-up response, newborn-aged patients and those receiving care in academic clinics had substantially higher odds of enrollment. Although subgroup estimates should be interpreted cautiously due to sparse data, in nonacademic clinics, Medicaid insurance was associated with lower odds of subsequent enrollment compared with non-Medicaid coverage. Sex and screening year were not significantly associated with referral acceptance in the overall model. Preferred language showed a modest association with acceptance, although estimates varied across clinic-specific models. Together, these findings highlight important differences in engagement across the WIC participation continuum and underscore the influence of clinical context and patient characteristics on both referral uptake and successful enrollment. Conceptualizing these steps as a continuum highlights potential points where health systems may intervene to improve participation, from identifying unenrolled families to supporting successful referral follow-through.

XSL•FO
RenderX

For practices planning implementation of a WIC screening and referral tool, screening modality and workflow integration are key considerations. In our sample, slightly more than a third of eligible participants in the nonacademic clinics completed WIC screening (1108/5385, 38%), suggesting meaningful implementation barriers. Although we attempted to standardize workflows through on-site education and partnership with clinic managers, some clinic staff may have viewed screening for FNP participation as outside their scope of practice or as potentially stigmatizing as demonstrated in our prior work, which could have contributed to higher rates of incomplete screening [24]. Additionally, nonacademic clinics relied on an automated EHR alert and screening during rooming—typically by MAs—rather than embedding screening within the provider note template, which could have contributed to differences in uptake of the screener. Prior studies have demonstrated alert fatigue and high override rates in clinical decision support systems [27-29], and our prior qualitative research similarly suggests challenges with alert timing and navigating workflows [24]. Future research could explore alternative methods for effective screening and workflow using an implementation science framework.

Screening during the clinical encounter by the health care provider may also provide the opportunity for more effective patient education about the benefits of WIC, given the knowledge gap among eligible WIC participants [30]. Caregivers report a high level of trust in their pediatricians, and their decision to enroll in the FNP can be influenced by a discussion with their pediatrician [31]. One prior study demonstrated that integrating WIC services into pediatric well-child and obstetric visits yielded 748 new WIC enrollments over a 21-month period, and the program was positively received by participants, staff, and providers [23]. More research is needed on integrating WIC referrals into clinical settings. These considerations may be particularly relevant given that referral acceptance and subsequent enrollment were higher in the academic clinic setting in adjusted models, underscoring the potential importance of workflow and counseling context.

Although consistent with national and state data, our findings suggest that determinants of WIC engagement differ across stages—from baseline participation to referral uptake and subsequent enrollment—highlighting opportunities for targeted strategies [6]. In particular, eligible non-Hispanic White families were least likely to report WIC participation at the first screening and less likely to accept a referral when offered, suggesting a need for tailored outreach and counseling to address barriers such as stigma or perceived lack of need. Prior research has elucidated potential reasons for WIC nonparticipation among this population, including stigma, feeling as if the program benefits are not needed, or worrying about taking away benefits from others [8,22,32]. Future studies should examine how participation in SNAP, including SNAP-only enrollment and changes in SNAP benefits over time, may influence acceptance of WIC referrals and subsequent enrollment decisions.

Policy Implications

There are several policy implications for this research. As health care systems increasingly adopt screening and interventions for health-related social needs, policies are needed that incentivize health care systems and clinicians to communicate with federal assistance programs such as WIC. Building EHR tools for WIC screening and referrals may not be feasible for all health care systems; policies are needed that incentivize EHR vendors to build these tools centrally, so they easily integrate with community partners to specifically address pediatric needs [33]. Furthermore, given that the data systems for patients and WIC clients are separate and unable to communicate with one another, data sharing policies could be modified to reduce the administrative burden of communication [34]. To support these policies, future research is needed to determine whether (1) EHR-based screening and automated referral improve enrollment and retention in WIC and (2) WIC referral by health care systems improves health outcomes. Our next steps for this study include optimizing the screening and referral tool workflow to expand across the entire health care enterprise, including additional counties and pediatric, family medicine, obstetrics, and gynecology clinics.

Limitations

There are several limitations to this research. First, these findings describe a specific EHR-based intervention implemented in 8 clinics in one geographic area. Results may not be generalizable to other settings. Second, FNP participation data were self-reported, and given the inability to verify enrollment in WIC for all participants, it is possible that errors existed in the self-reported data. However, preliminary unpublished data included a validation sample, indicating high accuracy between participants' responses and actual WIC participation, as verified by our county's WIC program. Furthermore, SNAP participation was not included as a covariate because the outcome definition of WIC enrollment included participants receiving both WIC and SNAP, creating overlap between the covariate and the outcome variable. Third, given the way the EHR screening tool was implemented in the academic clinic using the progress note template, if the responses were not documented, we could not calculate the percentage of patients who were not screened, which may introduce selection bias. Finally, we can only comment on associations between patient demographic characteristics collected in the EHR and FNP participation screening responses, WIC referral acceptance, and WIC enrollment. These associations are not necessarily causal, but we hope these data will inform future work as we continue to grow these datasets and optimize clinical workflows in our health care system.

Conclusions

A primary care, EHR-based WIC screening and referral tool can facilitate screening and referral to WIC. Direct, automated referrals to WIC from health care settings are an innovative method for potentially improving access to WIC and promoting health equity. Future research should examine the effectiveness of health care–based referrals on WIC enrollment and retention, the most effective method of referral from health care systems, and the intervention's impact on health outcomes. Qualitative research could explore clinical and patient perceptions to ensure equity in exploring differences by race and ethnicity.

Abstract

Background: More than 6 million children in the United States have asthma, and more than 20% are clinically obese. Youth with asthma and obesity are susceptible to poor health outcomes, including greater asthma symptom severity and hospitalizations, reduced physical activity, and poorer quality of life. Mobile health technologies can increase access to chronic disease self-management interventions, and family members can be powerful influencers given their substantial control over a child's behavior and home environment.

Objective: The Mobile Childhood Asthma Management Program (mCHAMP) app is based on the in-person Childhood Asthma Management Program (CHAMP) behavioral family intervention pilot trial of school-aged children with asthma and obesity. In this study, we translated the CHAMP content into digital content and conducted summative testing to measure the usability, learnability, and efficiency of the mCHAMP app.

Methods: We applied a sequential mixed methods approach. The mCHAMP app targeted adult caregivers of children living with asthma and obesity aged 6 to 12 years. A consumer-centered approach was used to guide the identification of user requirements and conduct of summative usability testing. While the mCHAMP app is primarily caregiver facing, it is intended to connect caregivers with registered nurse (RN) interventionists. Therefore, we sought feedback from RNs as key stakeholders.

Results: Caregivers (n=10) were female (n=10, 100%) and mostly African American (n=8, 80%), and half (n=5, 50%) had an annual household income of <US $25,000; most of their children (n=6, 60%) were in the 99th BMI percentile. Post-Study eHealth Usability Questionnaire scores indicated high overall satisfaction, usefulness, and quality of the mCHAMP app. Most caregivers (n=7, 70%) were able to complete all 15 tasks across the 6 modules with 2 or fewer hints. The average total time to complete all tasks was 17 (SD 3.9; range 11.4-24.1) minutes. Most caregivers (n=7, 70%) wanted information in static form but also preferred alternatives (eg, audio or video) to support flexibility with consuming the content. Caregivers expressed the need for more child-facing content as well as tailored decision support related to diet and exercise. RNs (n=5) strongly endorsed their role and

XSL•FO
RenderX

use of the mCHAMP app to promote self-management among caregivers of children with obesity and asthma. They noted the importance of integrating the mCHAMP app into a local electronic health record and existing workflows.

Conclusions: Caregivers expressed a desire for an intervention that was easy to use and could integrate into their busy family lives. We met this expectation based on the usability, learnability, and efficiency results of our study. The mCHAMP app has the potential to increase self-management for parents and pediatric patients with asthma with multimorbidity, which could improve patient and health system outcomes. The use of mCHAMP may also enable novel clinical outcome studies based on patient-reported data from the app.

Introduction

Background

More than 6 million children in the United States have asthma, and more than 20% are clinically obese [1]. Asthma and obesity are leading causes of morbidity, reduced quality of life, and health care costs [2]. Youth with asthma and obesity are especially susceptible to poor health outcomes, including greater asthma symptom severity and hospitalizations, reduced physical activity, and poorer quality of life [3-5]. Children with asthma and obesity can improve their overall health and quality of life when families engage in chronic disease self-management behaviors, including self-monitoring (eg, symptoms and diet), setting and achieving goals (eg, increasing physical activity), modifying the home environment (eg, trigger reduction and healthy food options), and collaborating with a health care provider [6-8].

Caregivers (ie, family members) can be powerful influencers of school-aged children (aged 6-12 years) during this developmental stage given their substantial direct and indirect control over a child's behavior and home environment [9-11]. However, family caregivers often have limited chronic disease self-management knowledge and struggle themselves to adhere to healthy behaviors [12-18]. There is a critical need for interventions that target family caregiver self-management behaviors during school age for children with asthma and obesity to optimize health and model self-management behaviors that can prevent downstream morbidity in adolescence and beyond [19].

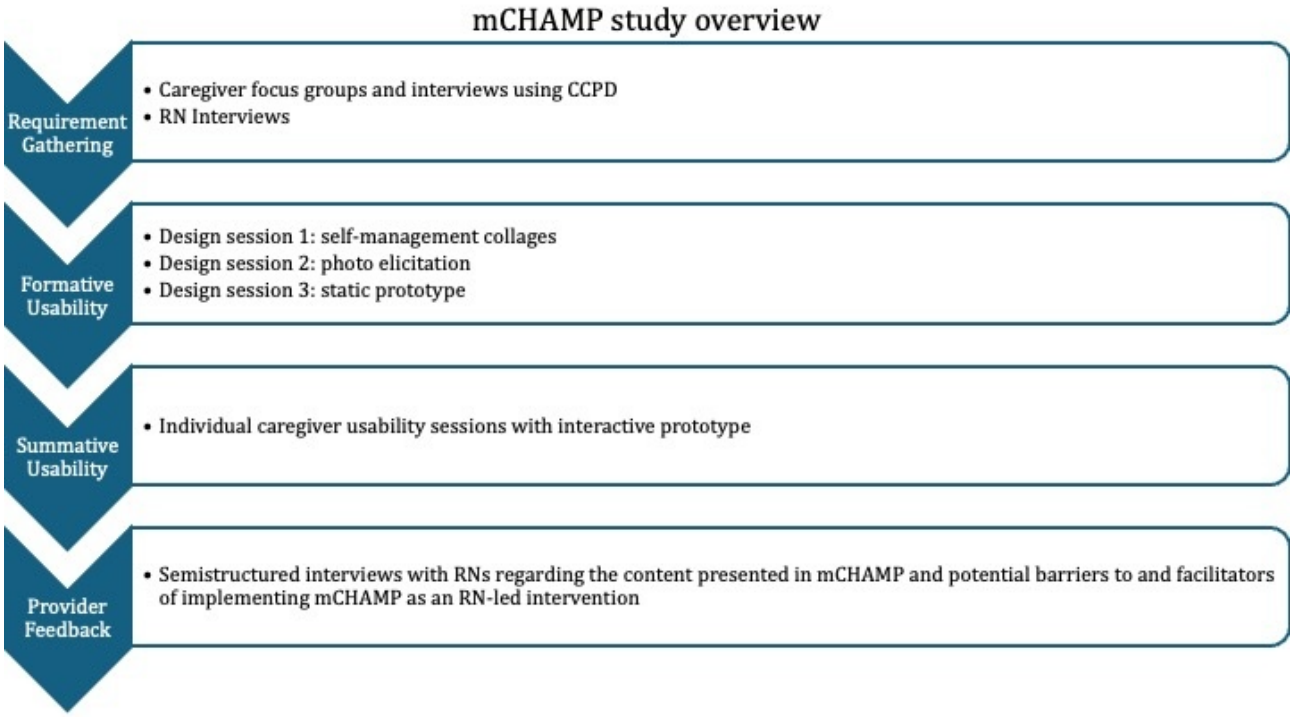
Behavioral family lifestyle interventions (BFIs) can reinforce family caregivers' self-management skills, resulting in health benefits for their children [20]. BFIs are informed by social cognitive theory, which posits that caregivers need knowledge and skills to engage in health-promoting behaviors [21,22]. BFIs target family caregivers as primary agents of change for health promotion. Caregivers learn child behavior management skills (eg, modeling and contingency management) to help them motivate and support their children in making healthy choices. BFIs can result in family caregivers developing self-management skills and self-efficacy to regulate their children's behaviors and creating a healthy environment [23,24].

BFIs are the most effective interventions for children with obesity [25,26]. Caregiver self-management skills promoted in BFIs are also critical for successful asthma management [27-29]. However, caregivers report numerous social determinant of health–related barriers (eg, access to health care services and health IT) to attending in-person sessions that limit self-management skill acquisition, behavior change, and benefits to their children [30-32].

Mobile health (mHealth) technologies can increase access to chronic disease self-management interventions. This is especially important given the ubiquity of smartphone ownership across racial and ethnic groups and socioeconomic strata [33,34]. Consumers perceive the usability and acceptability of mHealth interventions as very high. mHealth functionality can be multimodal (ie, text, audio, and visual) to accommodate various literacy levels. mHealth-supported interventions can enable flexibility in accessing and completing intervention components to improve intervention uptake and reduce the time commitment of consumers [35,36]. mHealth-enabled BFIs can reduce barriers for family caregivers in learning and role-modeling self-management skills to improve their children's asthma and obesity [30-32]. In addition, mHealth self-management interventions show promise in improving youth asthma and weight outcomes [37-40]. Individual tailoring to the caregiver via ongoing support from a health care provider can facilitate intervention engagement [39,41,42]. This is particularly important to caregivers of children with asthma and obesity as this multimorbidity adds significant complexity to disease management for caregivers [20]. Caregivers of children with asthma and obesity conveyed in our pilot work that they would value ongoing contact with a registered nurse (RN) as support for self-management. RNs have the requisite knowledge and skills to educate, motivate, and successfully assist families in using self-management skills to facilitate health behavior change, making them the ideal health professionals to support an mHealth-enabled BFI for caregivers of school-aged children with asthma and obesity [43,44].

Objectives

The Mobile Childhood Asthma Management Program (mCHAMP) is based on lessons learned from our in-person Childhood Asthma Management Program (CHAMP) pilot trial, a BFI with families of school-aged children (6-12 years) with



XSL•FO
RenderX

asthma and obesity [45]. The CHAMP intervention included 16 sessions over 3 months and encompassed topics such as collaborative ways for caregivers and children to establish healthier eating and exercise habits, healthy eating on a budget, goal setting, and progress tracking. In this study, we modified CHAMP into mCHAMP in 2 phases. Following the translation of CHAMP content, summative testing was used to measure usability, learnability, and efficiency. The focus of this paper is the summative usability testing of the mCHAMP app. However, a brief discussion of system development and formative testing is included for context.

Methods

An overview of this sequential mixed methods study is shown in Figure 1. Additional study design details are provided in the published protocol [44].

Figure 1. Overview of the study design. CCPD: consumer-centered participatory design; mCHAMP: Mobile Childhood Asthma Management Program; RN: registered nurse.

Ethical Considerations

The University of Florida Institutional Review Board - mCHAMP (Mobile Childhood Health and Asthma Management Program) approved all study procedures (IRB201801092), and all participants provided informed consent. The participation window ranged from October 2018 to December 2019.

System Development

The mCHAMP app targeted adult caregivers of children living with asthma and obesity between the ages of 6 and 12 years. A consumer-centered participatory design (CCPD) approach was used to identify user requirements, and summative usability testing was completed with caregivers to measure overall usability, learnability, and efficiency [46].

Using CCPD, we iteratively identified salient content and end user needs from the original CHAMP intervention and how to best translate that into the mCHAMP mobile app. Potential end users included family caregivers and nurses. Focus groups were the primary method of engagement with participants during initial system development. However, if participants were not able to attend one of the scheduled focus groups, individual interviews were conducted. The primary goal of these sessions was to identify which components of the CHAMP intervention resonated most with caregivers and the preferred format for those components [45]. Caregivers also described their families' unique barriers to asthma and weight management. The use of CCPD allowed us to better understand the perspective of community members who might benefit from our intervention and allowed us to build the mCHAMP app in line with community needs.

We continued to engage caregivers, starting with formative usability testing and ending with summative testing. Formative testing uses qualitative approaches iteratively to identify and fix usability problems with small samples [47]. We engaged caregivers in 3 formative sessions, which provided feedback on the design of our initial prototype. Following these sessions, we developed an interactive mCHAMP prototype for iOS and Android users in collaboration with MEI Research, a nonprofit organization that specializes in the development of medical education content, including mHealth apps. The resulting prototype was evaluated through summative usability testing, which is the focus of this paper.

Approach

Summative testing is used to evaluate a system's usability and commonly includes metrics such as time on task, errors, user satisfaction, and user interface challenges [47]. Overall usability,

XSL•FO
RenderX

or satisfaction, was assessed quantitatively using the Post-Study eHealth Usability Questionnaire (PSHUQ) and qualitatively through open-ended questions. To assess learnability, or ease of learning, we used time on task and errors. Efficiency was measured through the number of steps and overall time to complete a task.

Setting and Recruitment

We recruited caregiver participants using purposive sampling from an outpatient pediatric pulmonary clinic and a hospital-affiliated integrated data repository that allows researchers to receive a list of patients who meet inclusion criteria and have consented to be contacted about research studies. Caregiver participants were parents or legal guardians of children who were aged 6 to 12 years, had a physician-verified diagnosis of asthma for at least 6 months before study participation, had a BMI at or above the 85th percentile, and lived with the caregiver participant. Participants were required to speak and read English. We excluded participants who had any significant cognitive impairment or developmental delay that would interfere with study task completion. We recruited RN participants from the pediatric pulmonary division. RN participant inclusion criteria were (1) providing care for children with asthma and (2) having worked in that capacity for at least 1 year. Due to institutional review board restrictions regarding storage of information on potentially eligible patients, we did not collect data on the total number of individuals contacted or response rates.

The summative usability target sample was 10 caregivers. Studies that include 10 participants in summative testing should find an average of 95% of system errors and a minimum of 82% of system errors [48]. In addition to caregivers, we targeted a sample size of 5 RNs for feedback on the final prototype.

Procedures

The interactive mCHAMP prototype used in summative testing included six modules: (1) mCHAMP home screen, (2) Learning Center, (3) Monitoring Healthy Choices, (4) My Goals & Plan, (5) Parent Dashboard, and (6) Communication Center (Figure 2A-F). The home screen provides access to each section of the app. Within the Learning Center, users have access to general information about healthy eating, physical activity, and asthma symptoms in children aged 6 to 12 years. The Monitoring Healthy Choices section allows users to monitor their child's screen time, eating, asthma symptoms, physical activity, and weight over time. In the My Goals & Plan section, we give users a place to set weekly goals. We ask whether they completed their goal, and if not, ask what got in the way. We also give users a place to view their plan and what to focus on during the upcoming weeks. This includes a list of action items related to their goals, the modules they are reviewing, and when they next meet with the nurse. In the Parent Dashboard, users can see how well they are managing their goals. This area includes rewards earned and how their child's health has changed over time. The Communication Center provides a way for users to communicate directly with their nurse when they have questions about the program, their child's asthma symptoms, or making healthy choices. We note that this feature should not be used for any emergency health issues or medication advice. Instead, this is a way for users to list questions for their next scheduled meeting with their nurse.

Summative usability testing sessions were conducted with a research team member and a caregiver. Each participant engaged with the mCHAMP app using a research mobile phone with an operating system that matched their current personal device's operating system. We created a summative usability testing script that asked caregivers (n=10) to complete 15 total tasks across the 6 modules of the mCHAMP app. Study staff provided directed feedback only if participants were unable to complete a task that would impact subsequent tasks. Study staff asked participants to think aloud as they used the prototype and provided nondirective guidance when necessary. Screen recording captured participants' on-screen movements. Following some tasks, open-ended questions were asked (eg, "Would you talk out loud about what this means to you?") before prompting the next task. Following performance of all tasks, participants completed the PSHUQ [49].

Nurse Feedback

While the mCHAMP app is primarily caregiver facing, it is intended to connect with RN interventionists. Therefore, in addition to obtaining caregiver feedback, we sought feedback from RNs as key stakeholders. Following summative testing with caregivers, a sample of 5 nurses received a brief overview of the project and a demonstration of the app's functionality. Study staff (RJL and AF) conducted semistructured interviews with nurses. Questions were related to app content, the role of RNs in promoting patient self-management, and future implementation of a nurse-led intervention using this app in a pediatric pulmonology clinic or primary care setting.

Measures

Demographics

Caregivers provided their age, gender, race or ethnicity, marital status, educational level, and household income. They also provided their children's age and gender. RNs provided their gender, race or ethnicity, household income, and length of time working as an RN overall, in addition to time providing care to children with asthma.

Technology Use

Caregivers completed a brief technology use questionnaire adapted from the Health Information National Trends Survey to characterize how often they interacted with technology (eg, computers, cell phones, and tablets) and whether they used technology for health-related tasks or belonged to any social networking sites [50]. Information regarding general use of technology was collected to ensure that differences in usability metrics were not attributable to differences in general experience with technology as opposed to the mCHAMP app itself.

Usability

Overall usability, or satisfaction, was measured using the PSHUQ [49]. The PSHUQ comprises 18 items and uses a Likert scale ranging from 1 ("strongly agree") to 7 ("strongly disagree"). Subscales include (1) system usefulness, which measures the ease of completing tasks; and (2) system quality, which measures satisfaction with the quality of the information and interface. We calculated the mean and SD for each of the individual items. We calculated subscale scores by averaging the items in each subscale. We averaged scores across all items to create an overall satisfaction score. Overall scores can range from 1 to 7, with lower scores indicating a higher degree of satisfaction.

Learnability

Learnability refers to the ability of a novice user to become proficient in a relatively short period [51]. Learnability metrics included number of hints and errors coded in each session. Hints were defined as any statement by the study staff that aided the

XSL•FO
RenderX

caregiver in completing a task. Errors were defined as actions taken by participants that did not follow the expected steps in the script.

Efficiency

Efficiency is the average time it takes for users to complete a defined set of tasks [52]. Efficiency was measured through the total time to complete the tasks associated with a particular module and the number of individual steps taken to accomplish those tasks. Steps included the count of the following aspects: clicking (any click following the script), errors (any click that did not follow the script), error recovery (any click after the initial error to return to the task), entering text (any action involving the user typing into the app), and scrolling (any action taken to scroll through content on the app).

Analysis

Screen recordings were analyzed using NVivo (version 12; Lumivero) to describe and quantify usability measures. Recordings were coded using an a priori codebook that was developed by team members (RJL, KS, and YX) based on the usability testing script and planned usability metrics. After establishing intercoder reliability, 2 team members (KS and YX) coded these recordings using NVivo. Any disagreements on coding were resolved through discussion. Iterative content analysis was used for the open-ended questions and semistructured RN interviews.

Results

Caregiver Participants

Overview

Caregivers (n=10) were female (n=10, 100%) and mostly African American (n=8, 80%) and had an annual household income of less than US $25,000 (n=5, 50%; Table 1). Most of their children (n=6, 60%) were in the 99th BMI percentile. In terms of technology use, all caregivers (n=10, 100%) reported spending at least 2 hours per day engaging with their smartphone for activities other than phone calls, and half (n=5, 50%) reported 5 hours or more of daily use. All participants also reported belonging to a social networking site, and most engaged with digital health information (eg, websites and health-related apps).

Used the internet to look up health or medical information	8 (80)

XSL•FO
RenderX

	Values
Used mobile health apps on their phone or tablet	9 (90)
Used email, the internet, or an app to communicate with a physician or physician's office	7 (70)
Participated in an online support group for people with similar health or medical issues	1 (10)

Summative Usability

Participants' scores on the PSHUQ indicated high overall satisfaction, with a mean rating of 1.13 (SD 0.24) and possible scores ranging between 1 (highest) and 7 (lowest; median 1, range 1-1.67). Caregivers also reported high levels of usefulness (mean 1.08, SD 0.10; median 1.00, range 1.00-1.20) and quality (mean 1.16, SD 0.33; median 1.00, range 1.00-1.90).

Learnability

Most participants (n=7, 70%) were able to complete all 15 tasks across the 6 modules with 2 or fewer hints (Table 2). Overall, participants received 0.53 hints per module on average (SD 0.55; range 0-1.8) and committed an average of 0.38 (SD 0.42; range 0-0.67) errors per module. One data point for hints represented an outlier with a total of 11 hints over the 6 modules and an average of 1.83 hints per module. Data for errors did not include any outliers. All participants were able to complete module 1 (mCHAMP home screen) without hints or errors. Most (n=9, 90%) were able to complete the 5 tasks in the Learning Center with 1 or no hints. Participants were also able to complete the Monitoring Healthy Choices tasks with 1 or no errors (n=8, 80%) and 1 or no hints (n=9, 90%). Module 4, My Goals & Plan, was easily navigated by participants, with nearly all (n=9, 90%) not receiving any hints and only 10% (n=1) of the participants committing 1 error. The 2 tasks in module 5, Parent Dashboard, were more challenging, with half of the users receiving 2 or more hints (mean 1.2, SD 1.4; range 0-3). Users were able to use the Communication Center easily, with 70% (n=7) not requiring any hints; the remining 30% (n=3) required 2 hints each, and only 20% (n=2) of the users committed 1 error each.

Table 2. Learnability and efficiency scores.

Module	Learnability, mean (SD; range		Efficiency, mean (SD; range	
	Hints	Errors	Steps	Time (min)
1. mCHAMP home screen	0 (0; 0)	0 (0; 0)	1 (0; 1-1)	0.1 (0.1; 0.0-0.2)
2. Learning Center	0.6 (1; 0-3)	0.6 (0.8; 0-2)	16.4 (2.6; 11-19)	6.6 (1.8; 3.1-8.6)
3. Monitoring Healthy Choices	0.06 (0.7; 0-2)	0.5 (0.8; 0-2)	20.4 (8.3; 13-34)	3.1 (1; 2-5)
4. My Goals & Plan	0.2 (0.6; 0-2)	0.1 (0.3; 0-1)	14.2 (2; 10-17)	3.2 (1.2; 1.4-4.6)
5. Parent Dashboard	1.2 (1.4; 0-4)	0.9 (1.1; 0-3)	16.8 (2.5; 14-23)	1.6 (0.7; 0.9-2.7)
6. Communication Center	0.6 (1; 0-2)	0.2 (0.4; 0-1)	16 (3.6; 9-21)	3.2 (1.7; 1.2-2.3)

Efficiency

The average total time to complete all tasks across the 6 mCHAMP modules was 17 (SD 3.9; range 11.4-24.1) minutes. Users spent the most time on the Learning Center (mean 6.6, SD 1.8; range 3.1-8.6 minutes), which included 2 videos totaling 1.5 minutes. Users completed module 1, the home screen, most quickly (mean 0.1, SD 0.04; range 0.02-0.17 minutes), followed by module 5, taking an average of 1.6 (SD 0.69; range 0.9-2.72) minutes to view the graphs and access the rewards. Modules 3, 4, and 6 took between 2.49 and 3.23 minutes on average. Table 2 provides efficiency data.

User Preferences

Electronic (Audio or Visual) Media

Participants felt that the videos were a good length (less than 1 minute each). They also liked the use of color and felt that the animation made them enjoyable and inviting to children and caregivers. When asked whether they preferred one video over the other, nearly half (n=4, 40%) of the participants talked about the importance of matching the gender of the character to the child watching, and 10% (n=1) also commented that it was important to depict racial diversity. A few participants (n=3, 30%) preferred the video that gave actionable information about activity and included more peer interactions. However, 10% (n=1) of the participants noted that they preferred the video that depicted how asthma can be isolating to a child because they felt that it was important for children to know that their experience is common. That participant also liked how that video included the experience of the child and the caregiver.

When asked about video content, caregivers were generally positive (n=9, 90%), with only 10% (n=1) stating that it was not valuable. That participant stated a preference for engaging directly with the nurse rather than with videos. Some participants (n=2, 20%) felt that it was important for content to be engaging for both children and adults, whereas 10% (n=1) of the caregivers stated that they would pass the app to their children and say, "Here you go. Mommy got this. You might wanna read it. You might wanna listen at it. It's cute" [U18].

However, there was a strong preference (n=9, 90%) for child-facing content. Participants stated that information about activity levels was particularly important (n=5, 50%), with 20% (n=2) stating that they did not know that being active was

XSL•FO
RenderX

important for asthma control and 10% (n=1) stating that they sometimes struggled to encourage activity even though they knew that it was the right thing to do. One participant would have liked additional information on identifying the warning signs of an asthma attack. The videos may also meet the needs of health care providers, with one caregiver stating that her physician wished she had a child-friendly video to explain what happens in the lungs during an asthma attack at their last appointment.

Static (Text) Media

Regarding written content, most caregivers (n=7, 70%) were comfortable and wanted the information in a static form but wanted an alternative form of media to support flexibility and choice regarding how to consume the content. Caregivers overwhelmingly supported the idea of having either videos or a "read aloud" audio function (n=10, 100%).

Caregiver Engagement

When asked about the survey task, caregivers reported it being easy to complete (n=9, 90%) and easy to navigate (n=2, 20%). One participant did voice concerns about how accurate they could be regarding entering information as their child spent so much time at school and in other activities where they did not see food or activity choices. There was also one comment about the use of the label "self-report" and that this phrase might be jargon; the use of more plain language for each task (eg, "food log") would be better.

Features that participants discussed in the reward section included a preference for tracking progress toward goals or visibility of status (n=4, 40%), animated congratulations when awards were unlocked (n=4, 40%), streak tracking to encourage consecutive goal achievement (n=3, 30%), and tailored notifications with actionable ideas when goals had not yet been achieved (n=2, 20%). The importance of visibility of status was described by one user as follows:

> *Okay, I did it without my asthma gettin' in the way. It'd convince him to keep goin' forward instead of stoppin' or not wantin' to do it because of his asthma.* [U16]

When asked about the reward center, many users (n=6, 60%) reiterated the desire for child-facing content. Many (n=5, 50%) talked about the value of having both child-facing content and caregiver-facing content. This was sometimes described as having one account per family, with the ability to log in on multiple devices and select either a child or caregiver role. When parent-facing content was discussed, the use of minimalist design using numbers rather than stickers or icons was described (n=2, 20%), and more icons or visual depictions were preferred for child-facing content (n=3, 30%). One user would have liked to see additional nutrition-related content in this area, and one user suggested adding interactive game content to help teach health promotion principles.

The concept of person-centered support was also observed in the preference for tailored notifications, with one user stating the following:

> *Yeah, like at the end of the week, when a child hasn't met their goals, it's okay to not always succeed, as long as you keep trying, or try, try, try again. You get knocked down, try again. Tomorrow's a new day. There's a thousand statements that you could put in there. Just some kind of a support.* [U17]

One participant valued the automated integration of Fitbit data, and another commented on the importance of a mobile app for in-the-moment data entry for logging symptoms. One participant also stated that she would have liked a way to interact with other caregivers (eg, peer support).

Health Care Provider Engagement

When asked about the feature to connect with a nurse, most (n=8, 80%) liked the ability to collaborate with the nurse, with some (n=3, 30%) stating that this feature might improve their access to care. The video component to the nurse communication was important to at least one caregiver, and 20% (n=2) commented about the need to have a specialized nurse knowledgeable about nutrition. The only difficulty discussed regarding the Communication Center was in navigating back to the main content after speaking with the nurse via Zoom.

RN Feedback

Semistructured interviews with 5 nurses who provided care to pediatric patients with asthma were completed. Nurses were recruited from diverse settings, including primary care, specialty care, and clinics serving patients with varying socioeconomic statuses. Inclusion of diverse participants allows for insight into potential need and important contextual factors in diverse settings for future implementation studies.

All 5 nurses strongly endorsed the role of the nurse to include education and promotion of self-management (self-efficacy). For example, nurses indicated that "Oh, yeah, that's our core function" and "that's what nursing does. Nursing is the education point of healthcare." Nurses all endorsed that mCHAMP had necessary activity-related content. One felt that there was room for improvement with the nutritional content. Several nurses also expressed concerns regarding low levels of literacy in the target population. This was further supported by nurses recommending additional video and pictorial content. Nurses liked that both genders were represented in the videos currently integrated into mCHAMP. Nurses also responded favorably to the Parent Dashboard and Communication Center content. They particularly liked the ability to see trends in the caregiver dashboard and the use of video in the Communication Center to enable some visual assessment compared to a phone-only interaction. They liked the use of in situ patient-entered data and the ability to monitor pertinent data in between appointments.

The use of mCHAMP in primary care was endorsed by all but one nurse (4/5, 80%), who felt that she did not have enough knowledge of the primary care environment to provide an informed response. Most participants also supported the use of mCHAMP within specialty care, and some proposed the use of a centralized nurse with specialized asthma experience to enable smaller clinics to participate in the program. Several nurses also stated that integration of mCHAMP data into the electronic

XSL•FO
RenderX

health record (EHR) would be important to the feasibility and sustainability of the intervention. Nurses also talked about the importance of integrating the intervention into existing workflows to promote health care provider buy-in. To achieve integration of data within the EHR, a health care provider dashboard was recommended.

Discussion

Principal Findings

The overarching goal of this study was to conduct summative usability testing of the mCHAMP app with caregivers and nurses. Overall, the mCHAMP app was viewed positively by caregivers, as evidenced by receiving high ratings for satisfaction, perceived system usefulness, and quality on the PSHUQ. Our results are comparable to findings from other health technology usability studies. Sheehan and Lucero [53] reported similarly favorable PSHUQ scores (mean 1.58; median 1.38) for their Self-Assessment via a Personal Health Record fall prevention system among older adults, demonstrating high satisfaction with system usefulness (mean 1.84) and quality (mean 1.43), with possible scores ranging between 1 (highest) and 7 (lowest). Both studies show that users found these health self-management systems easy to use and of high quality, with our caregivers rating the mCHAMP app slightly more favorably on usefulness (mean 1.08, SD 0.10) compared to the Self-Assessment via a Personal Health Record study. These comparable satisfaction scores across different health domains and user populations suggest that health applications can achieve high user acceptance when developed using well-designed, theory-driven usability frameworks.

Furthermore, our metrics of learnability and efficiency for the mCHAMP app with caregivers were favorable. Caregivers were able to complete our list of prespecified module tasks with few hints, and the average time spent on each module of the app ranged from under 1 minute to just over 6 minutes. Consistent with our usability data, qualitative feedback provided by caregivers during the think-aloud testing indicated that they were pleased with several mCHAMP app features, including the animated videos and ease of completing self-report surveys. Caregivers expressed a desire for an intervention that was easy to use and could integrate into their busy family lives during requirement gathering sessions that we conducted when designing the mCHAMP app. We appear to have met this expectation based on the usability, learnability, and efficiency data from this study.

A main point of innovation for the mCHAMP app is that it leverages the expertise and training of RNs as interventionists to develop caregiver self-management skills. An important finding from our usability testing was that caregivers were indeed enthusiastic about working with an RN interventionist to facilitate their use and uptake of self-management skills via the mCHAMP app. Caregivers stated they liked having the ability to reach out via videoconference to the RN interventionist rather than googling or calling as it would give them the ability to show the RN what was going on rather than being limited to a description over the phone. Previous research has demonstrated that technology-based interventions that incorporate RNs as care deliverers are feasible and efficacious at reducing morbidity in pediatric asthma [54,55]. Given the ubiquity of mobile phones, and in the context of a health care system that emphasizes care within a medical home model of care [56], the use of RNs as interventionists in the mCHAMP app to concurrently target asthma and obesity extends prior work and generates confidence that there is a viable framework for scalability.

Given the central importance of self-monitoring in the self-management of chronic illness, we designed the mCHAMP app to enable caregivers to enter data (eg, asthma symptoms, food logs, and screen time) and synchronize with a Fitbit to facilitate tracking of important health behaviors and progress toward self-management goals [57,58]. Caregivers responded positively to these components of the mCHAMP app and had little difficulty completing surveys during testing. Moreover, a general theme of feedback from caregivers was that they valued how their children's health data could subsequently lead to a more personalized intervention experience. Examples given by caregivers included informing more meaningful interactions with the RN interventionists and that having their children's health data in a central location could increase their accuracy when attending appointments with their children's physicians. We posit that these data, if regularly accessed by the caregiver, could also help strengthen connections between health behaviors (eg, physical activity levels and food intake) and important outcomes (eg, asthma symptoms and weight) in children with comorbid asthma and obesity.

Caregivers noted several areas in which we could make further improvements to the mCHAMP app. Specifically, caregivers wanted flexibility to engage with educational content on the app in multiple ways, including the addition of more videos and read-aloud functions to the current prototype. Notably, while using the Parent Dashboard module, participants required more hints compared with other sections of the mCHAMP app. Our review of the data indicated that most hints were required following the task prompt "Show me how you would access the graphs that show changes in your activity and your child's activity over time," with more than half of the participants requiring at least one hint before selecting the Parent Dashboard. Common incorrect selections by caregivers included them selecting the Learning Center, Monitoring Healthy Choices, or Communication Center modules. The range of actions taken by caregivers suggests that we should refine the mCHAMP app to better differentiate where visual health data are stored to improve usability.

Many caregivers indicated that they wanted the mCHAMP app to include child-focused content. We considered including child-focused content during our initial development of the mCHAMP app but decided to focus on caregivers due to the developmental level of our target sample (aged 6-12 years) and based on previous studies that have demonstrated that in-person caregiver BFIs are as efficacious as those that include caregiver-child dyads [24]. In addition, the emerging data on the added benefit of including children in eHealth or mHealth interventions for child weight management are mixed. However, recent data suggest that including children as active recipients of a technology-based intervention is associated with increased

XSL•FO
RenderX

efficacy [59]. Thus, an important direction for our future work in this area is to identify developmentally appropriate ways to include children in mCHAMP.

RNs also had a favorable response to the mCHAMP app. They valued the use of caregiver-entered health data, which is consistent with the literature on the benefits of patient-reported outcomes. Systematic use of patient-reported data in between care may support patient-provider communication in addition to fostering clinician awareness of health status in between episodes of care [60]. RNs also recommended collecting data on medication use to provide information that may be important for asthma management. This recommendation is also supported by literature on the use of patient-entered data to facilitate medication adherence among patients with chronic diseases [61]. Finally, RNs also had positive feedback regarding the videoconferencing features of the mCHAMP app as a mechanism to provide support between intervention sessions.

Nurses raised important contextual factors, such as the ability to integrate mCHAMP into the EHR and potentially differing workflows among participating clinics as concerns related to future implementation. These concerns could be mitigated through the use of workflow analysis in future studies and the use of interoperability standards to enable integration of data into the EHR.

Limitations

While our usability evaluation of the mCHAMP app was strengthened by the inclusion of the perspectives of potential end users or family caregivers and health care providers, there are evaluation weaknesses overall that should be addressed in future research. First, we observed that all the usability evaluations were conducted using the iOS operating system based on family caregivers' actual mobile phone type. Second, future research should include additional family caregivers whose children are affected by obesity and asthma that were not included in our study, namely, Hispanic English- and Spanish-speaking caregivers. Third, while our sample size of 10 caregivers was adequate for identifying usability issues, this limits our ability to fully understand the range of experiences and preferences across diverse populations of caregivers managing childhood asthma and obesity.

The homogeneous nature of our sample may not capture usability challenges that could emerge among caregivers with different technological comfort levels or cultural backgrounds. Only 40% of child patients with asthma are coded as Black or African American in the data repository, which does not contain information on obesity. Moreover, without demographic data on caregiver characteristics in the broader repository population, we cannot fully assess the extent of these potential biases. In addition, there are opportunities to engage family caregivers from varied geographic locations and settings, including primary care in urban and suburban clinics with health care providers whose experience may be different from that of health care providers in specialized pulmonary clinics.

Conclusions

Our study was able to identify key components of the original CHAMP intervention to develop and test the usability of the mCHAMP app by engaging stakeholders using the CCPD process. Caregivers and nurses had favorable feedback on mCHAMP. With some minimal revisions, the mCHAMP app could be used in future pilot-testing. This will enable the research team to test the hypothesis that translating CHAMP from an in-person intervention to an mHealth intervention will improve retention rates while maintaining high levels of satisfaction. The mCHAMP app has the potential to increase self-management for pediatric patients with asthma dealing with multimorbidity, which could translate into improved patient outcomes and long-term benefits for health systems. The use of mCHAMP may also enable novel clinical outcome studies based on patient-reported data from the app.

Abstract

Background: Many parents today use digital or mobile health (mHealth) resources for parenting information and support. Thus, interventions or programs to support parenting delivered in this way are a rapidly growing area of innovation and research. Evidence indicates that face-to-face interventions that provide education and support for parents about infant sleep can have positive impacts on both infant sleep and maternal mood. However, there is limited research on the delivery of such interventions via digital or mHealth platforms. SleepWellBaby is an infant sleep mobile app for parents with infants and young children. The app provides parents with a 7-day program that may be repeated according to individual user demand, with information and interactive features aimed at supporting parents to understand infant sleep, and providing advice about strategies to support sleep in a responsive way.

Objective: The study objectives were (1) to determine engagement with, and acceptability of, an mHealth-delivered parenting program to support infant sleep and (2) to investigate the impact of the program on parental fatigue, emotional health, and parenting competence, confidence, and self-efficacy.

Methods: A multimethod quasi-experimental pre-post study design was used. Participants were parents of infants aged under 6 months, recruited through online advertising. Participants completed baseline questionnaires, then 2 further follow-up questionnaires at 7 days and 30 days post baseline. These questionnaires captured participant demographics (baseline) and perceptions of the program (follow-up), in addition to measuring parental fatigue (Fatigue Severity Scale), parent sense of competence, confidence, and self-efficacy (Me as a Parent Scale), and symptoms of anxiety (Generalized Anxiety Disorder 7-item scale) and depression (Edinburgh Postnatal Depression Scale) at all time points. Open-ended text responses were also collected at the 2 follow-up surveys. Questionnaire data were linked with participants' engagement with the program (Engagement Index), measured using app analytics.

Results: Participants' (baseline: n=700; 7-d follow-up: n=339; and 30-d follow-up: n=220) engagement with the program varied; however, the majority reported cessation of app use by 1 month. Most participants were broadly satisfied with the program, finding the app easy to use and understand, and reported they could trust the information on the app. Those participants who had higher engagement or found the program most helpful for their sleep and their infant's sleep showed the greatest improvement

XSL•FO
RenderX

in their fatigue. Qualitative feedback from participants noted that while many found the app a lifeline with helpful information and features, others noted unintended negative impacts, such as spending too much time on their phone.

Conclusions: Delivery of an infant sleep program via mHealth is effective for and acceptable to many parents. While not preferred by all parents, mHealth is an accessible, low-cost, and high-reach mode of providing information and management strategies for parents experiencing early parenting difficulties.

Introduction

Sleep and settling difficulties during infancy and childhood are common and can be challenging for many families [1]. In an Australian study, 39% of mothers with infants at 1 month of age reported infant sleep difficulties [2]. While sleep disturbances in early infancy are normal and there is no commonly applied clinical definition of what constitutes a sleep problem in infancy [3], sleep and settling difficulties are generally understood to be related to infant regulation, with sleep difficulties potentially related to *dys*regulation [1]. Infants and their parents are interconnected in the management of infant dysregulation, as an infant needs a primary caregiver to facilitate regulation [4]. To do this, a parent needs to be attuned to their infant and to accurately observe, interpret, and respond to their infant's cues (eg, facial expressions and crying) in a warm, consistent, and timely manner [4,5]. This skillful parenting interaction takes time to develop and can be impacted by many factors, including infant temperament, parental mood symptoms, and parents' confidence and self-efficacy in their parenting [5].

Prevention and early support for families experiencing difficulties are important, as infant regulatory issues can continue into later infancy and toddlerhood [1,6], with significant implications for both child and parental mental and physical health. Disrupted sleep and frequent night waking in infancy and toddlerhood are associated with social, emotional, and behavioral challenges in toddlers [7] and with fatigue and mental health disorders in parents [8]. Thus, infant sleep and settling difficulties can impose a substantial burden on health systems: parents reporting infant regulatory issues often use multiple health services in their search for support [9].

Interventions providing education and/or support to parents regarding infant sleep can have positive impacts on infant sleep and maternal mood [10,11]. A Cochrane review of randomized controlled trials of postnatal education with parents of infants aged 2 months or under found interventions that included education about infant sleep led to greater length of infant sleep at 6 weeks of age [10]. A review and meta-analysis of randomized controlled trials of psychosocial and sleep-focused interventions with mothers and infants aged 12 months and under found a small but significant positive effect on infant sleep and maternal mood, as measured by the Edinburgh Postnatal Depression Scale (EPDS) [11]. A recent umbrella review of 5 systematic reviews (including 24 individual studies involving several thousand families) found that behavioral sleep interventions increased total nighttime sleep in infants and may also help reduce nighttime wakings and improve maternal mental health [12]. However, most interventions in these reviews had multiple components and were based on different approaches to infant sleep, for example, behavioral management versus intuitive parenting, making it difficult to isolate the component or approach that is most effective.

In Australia, early parenting centers such as Tresillian are a primary source of support and intervention for parents who experience challenges with their infant's sleep [13]. Such centers have been part of the Australian health landscape for more than a century and currently provide group, day, and residential programs for parents of children aged 0 to 3 years, with challenges related to sleep, settling, feeding, and/or parenting capacity and confidence, and, in some settings, mental health support [14,15]. While these centers house considerable clinical experience and expertise, there are substantially fewer published studies reporting the efficacy of infant sleep interventions delivered by these centers, compared with behavioral sleep programs overall. However, the available evidence indicates these programs are associated with similar improvements in infant sleep and/or parent mental health to those outlined earlier [13,15-17]. A recent systematic review and meta-analysis of behavioral interventions for problematic infant sleep and unsettled behavior incorporated 16 studies, 8 of which were in Australian early parenting centers [18]. Consistent with earlier meta-analyses, this research synthesis found mild to moderate improvements in infant sleep and maternal mental health across interventions.

Most of the studies and research syntheses outlined earlier were based on face-to-face programs and consultations, and not all parents are able to attend in-person programs. Parents face a range of barriers, including long waiting lists, lack of transport, difficulty accessing childcare, and geographical isolation [19]. In addition, there has been a generational shift in the preferred sources of support sought by parents. Millennial and Gen Z parents, born from 1981 onward, who have themselves grown up in the digital age, naturally choose digital tools to support their parenting [20]. With these factors in mind, and fueled by necessity during the recent COVID-19 pandemic [21], there has been a dramatic increase in online tools and programs for parents over the past decade, to the extent that they are now ubiquitous [20]. An increasing number of these digital or mobile health (mHealth) parenting tools and programs are delivered through smartphone apps. A review published in 2020 found 421 maternal and infant health smartphone apps with approximately

XSL•FO
RenderX

25% (n=102) developed by a health care provider or affiliated provider [22].

As a problem that causes substantial anxiety for parents, infant sleep is the focus for many new parenting apps. Evidence for the efficacy and/or acceptability of these interventions is still emerging, and findings are mixed. Leichman et al [23] evaluated the real-world effectiveness of an mHealth behavioral sleep intervention among caregivers of 404 infants aged 6 to 11.9 months and found improvements in a range of sleep-related outcomes with the greatest improvements for those infants classified as problem sleepers at baseline.

While apps have been shown to be acceptable to parents for health service delivery [24,25], reviews assessing the quality of information on infant health apps indicate poor quality of information [26,27]. Apps are expensive to develop and maintain—therefore, most parenting apps are commercial enterprises, which may prioritize profit over evidence-based content [20]. Even where free evidence-based apps do exist, parents often prefer their commercial counterparts due to their superior design, interactivity, and customization [20]. Very few of the commercially available apps currently on the Google Play Store or the Apple App Store are developed by or with health organizations [22], and few have been evaluated [28]. Parenting apps take their place in an overwhelming ocean of parenting information available to modern parents. A 2022 Google search for the term "parenting" returned an astonishing 1,850,000,000 results [29], highlighting the need for high-quality information and programs that are appealing, user-friendly, readily available, and easily distinguishable from less sound material [30].

In 2019, the SleepWellBaby app was developed through a partnership between SleepFit, a sleep app development company, and Tresillian, a not-for-profit early parenting support service, in an effort to increase parents' access to high-quality advice, education, and guidance. The content of SleepWellBaby is based on the Tresillian approach to infant sleep and settling. This approach focuses on education about normal infant or child sleep, natural sleep rhythms (eg, day or night and circadian rhythms), infant cues (communication), and responsive settling techniques such as hands-on settling [31]. Tresillian's approach is about supporting positive parent and infant relationships through improving parents' understanding of infant cues and supporting parents to reflect on personal or relational elements that may be impacting how they respond to their infant or child [31].

The purpose of this study was to determine the engagement with and acceptability of SleepWellBaby, an app-based parenting program to support infant sleep, and to investigate the impact of the program on parent fatigue, emotional health, and sense of competence, confidence, and self-efficacy.

Methods

Study Design

This was a multimethod quasi-experimental pre-post study.

Intervention: The SleepWellBaby App

SleepWellBaby is an infant sleep app for parents. The SleepWellBaby app provides parents with a 7-day program that may be repeated as many times as users desire. It is tailored to the infant's or child's age and follows a feed-play-sleep daily rhythm. Parents are prompted to complete daily check-ins and sleep tracking, which help in monitoring progress over the 7-day program. There are also daily top tips, frequently asked questions, and "wisdom" cards on feeding, playing, and sleeping. The information covered includes an understanding of how normal developmental stages impact sleep, natural sleep rhythms (eg, day or night and circadian rhythms), infant cues (communication), tips for creating a safe, conducive sleep environment for infants or children, and support about infant or child settling and resettling [31]. The app also includes information and prompts for parents to access more intensive support as needed, for example, telephone support line and information on how to book a face-to-face appointment with Tresillian. Tresillian is Australia's largest early parenting service located in New South Wales on the east coast of Australia. Tresillian provides services to thousands of families annually [32]. SleepWellBaby, while a separate program, was based on the Tresillian approach, developed with Tresillian clinicians, and is endorsed and promoted by Tresillian.

Recruitment

Potential participants were recruited through online advertising, primarily through paid advertising on Facebook, posts on the Tresillian Facebook and Instagram social media pages, and posts on the Sydney Institute for Women, Children and their Families Twitter/X and LinkedIn social media pages. Eligible for inclusion were parents or carers who were aged 18 years and older, had infants aged less than 6 months, could read and understand the English language, lived in Australia, and had not previously used SleepWellBaby.

Potential participants followed a link to the study landing page containing participant information housed on the REDCap (Research Electronic Data Capture) platform hosted at Sydney Local Health District [33,34] and completed eligibility questions. Eligible participants completed an eConsent form, then completed the baseline survey, and received a code to access the SleepWellBaby app. Participants were recruited from April 30, 2021, to November 30, 2021. SleepWellBaby versions 1.5 to 1.7 were in use during this period.

Measures

Demographic Data

At baseline, each participant reported their age, carer role (eg, mother and father), employment, education, and country of birth. They also reported information related to the family, including relationship status, number of children, main language spoken at home, and postcode. Characteristics of the infant were collected, including infant age, gender, if they were born prematurely, and current milk feeding status.

Engagement

Engagement with the app was measured using an Engagement Index (EI) framework [35]. The EI includes 5 subindices, which

XSL•FO
RenderX

are scored between 0 and 1. These indices included click depth index, loyalty index, recency index, interaction index, and feedback index. Metrics related to each subindex were extracted from the SleepWellBaby app analytics database (detailed in Multimedia Appendix 1). To calculate an overall EI score out of 100, these subindices are summed, divided by the number of indices, and multiplied by 100. A higher score indicated higher engagement with the app. Using this framework, participant engagement in the first 7 and 30 days was calculated to generate 2 EI scores [35]. In addition, 3 self-report questions were also asked at the 7-day and 30-day surveys: parents were asked whether they were still regularly using the app (yes or no; if no, asked to further select why they no longer use the app), if they thought the program assisted in improving their sleep (program helped parent sleep scale, 5-point Likert scale, "strongly disagree" to "strongly agree"), and if the program assisted in improving their infant's sleep (program helped infant sleep scale, 5-point Likert scale, "strongly disagree" to "strongly agree").

Acceptability

Acceptability of delivering an mHealth infant sleep and settling program was measured in 2 ways. First, a Net Promoter Score (NPS) [36] was collected within the app. Second, a 10-item "Parent Satisfaction Scale" was developed based on items from previous research on parents' engagement with an infant health app [35]. Each item was measured on a 5-point Likert scale, from 1 ("strongly disagree") to 5 ("strongly agree"). The satisfaction scale was designed to sum into a total scale ranging from 10 to 50, with higher scores indicating higher satisfaction with the program. These items were collected at both the 7-day and 30-day follow-up surveys.

In the survey, participants were also prompted to provide text responses through open-ended questions at the 2 follow-up surveys. More than half of the participants provided open-ended text responses on their perceptions of the app. Input was requested across several open-text questions at each of the survey time points. Questions included "Please describe reasons for not using SleepWellBaby" and "Is there anything else you'd like to add about SleepWellBaby?".

Parent Well-Being Outcomes

Aspects of parent well-being measured included fatigue, parenting confidence, and emotional health. These were measured at baseline, 7 days, and 30 days. Fatigue was measured via the 9-item Fatigue Severity Scale (FSS) [37]. This scale measures symptoms of fatigue, asking participants how much they agree with the items on a 7-point scale. This scale has been used in samples of mothers attending residential child and family health services [38]. A total score is calculated and ranges from 9 to 63, with higher scores indicating greater fatigue severity.

The Me as a Parent (MaaP) questionnaire was used to measure parents' sense of competence, confidence, and self-efficacy in their parenting [39]. This 16-item scale was developed and validated in an Australian population of parents, and measures parenting self-regulation incorporating 4 domains that the authors describe as a "…global sense of competency and confidence in parenting" (p.2853) [39]. A total score is calculated and ranges from 16 to 80, with higher scores indicating a greater sense of competence, confidence, and self-efficacy in their parenting.

Emotional health was measured with 3 instruments: a short mood screener designed for the SleepWellBaby app [40], the EPDS [41], and the Generalized Anxiety Disorder 7-item scale (GAD-7) [42]. The EPDS has been commonly used in previous research on sleep programs [11], and both the EPDS and GAD-7 are widely used as screening tools for emotional and mental health. For these 2 scales, a total score is calculated and ranges from 0 to 30 for the EPDS and from 0 to 21 for the GAD-7, with higher scores indicating greater symptoms of depression and anxiety.

Analysis

Engagement

Descriptive statistics, proportions, medians, means, SDs, and 95% CIs of the 7-day and 30-day EI and subindices were calculated. Parents' continued use of the app, program helped parent sleep scale, and program helped infant sleep scale were similarly described. Program helped parent sleep scale and program helped infant sleep scale were measured with a 5-point Likert scale, with responses later collapsed into 3 levels: "strongly agree and agree," "neutral," and "strongly disagree and disagree." The McNemar-Bowker test was performed to compare responses to this question at the 2 follow-up time points.

Acceptability

The questions related to the continued use of the app and the NPS are reported using descriptive statistics (proportions, means, and SD). Exploratory factor analysis was applied to the 10-item Parent Satisfaction Scale, which showed a 1-factor solution with good internal consistency (Kaiser-Meyer-Olkin test=0.854; Bartlett test of sphericity $P<.001$; variance of first factor, 49.355%; Cronbach $\alpha=0.88$ [43]). Therefore, these 10 items were summed, producing a single "satisfaction score." Independent 2-tailed *t* tests were used to explore differences in the NPS and satisfaction score by the following dichotomous demographic variates: education (university qualification or higher vs no university qualification), number of children (1 child only vs 2 or more children), symptoms of anxiety and depression at baseline (baseline EPDS ≥13 and/or GAD-7 ≥15 vs baseline EPDS <13 and/or GAD-7 <15), and parent perception at baseline of infant daytime and nighttime sleep problems (yes or no). Correlation between the satisfaction score and the EI was examined with Spearman ρ.

For the open-ended text responses, thematic analysis was conducted using the following Braun and Clark's 6-step process: (1) familiarization (reading the response), (2) initial descriptive coding, (3) forming themes (by searching for patterns and comparing and contrasting codes), (4) checking themes (internally, checking that the quotes and codes sit together as a theme, and across the dataset, checking that the themes reflect the data, and checking for disconfirming data), (5) naming themes, and (6) reporting the findings [44]. Using Lumivero NVivo (version 13) software [45] (AMM used inductive coding to code all responses and then identified themes). JA and HC

XSL•FO
RenderX

each read and coded a portion of the data separately. Over several meetings, discussions, and reviews, confirmation of the coding and themes was conducted by all 3 authors (HC, JA, and AMM).

Parent Well-Being Measures

Separate hierarchical multiple regression models were conducted to analyze the impact of engagement with the program on 4 of the outcome variables measuring fatigue (FSS), parenting confidence (MaaP), and emotional health (GAD-7 and EPDS). To ensure that outcomes were analyzed in relation to app *use* rather than the mere *download* of the app, the 7-day EI was the predictor variable for the outcomes measured at 7 days, and the 30-day EI was the predictor variable for the outcomes measured at 30 days. In addition to engagement, another predictor of interest was parents' perception of how the app assisted in improving their own and their infant's sleep (program helped parent sleep scale and program helped infant sleep scale). Several covariates were also included to adjust the models. The blocks were structured as follows: EI (predictor) and target outcome (dependent variable) with baseline score of target outcome (model 1); program helped parent sleep scale and program helped infant sleep scale (model 2); parent age at baseline, infant age at baseline, parent education, number of children, and pregnancy complication reported as baseline (model 3); and baseline score of the 3 other outcome variables (model 4).

IBM SPSS Statistics (version 29) [46] was used for all analyses, and *P* values <.05 were considered statistically significant.

Ethical Considerations

Ethics approval was provided by Sydney Local Health District (RPAH Zone) Human Rights Ethics Committee (Protocol X20-0548 & 2020/ETH03215) prior to the start of the study. All study procedures were conducted in accordance with the ethical standards of the Declaration of Helsinki. Consent was obtained from all participants through an eConsent framework, including participant information and electronic consent form. Participants provided consent for research data collection and consent to access and match these data with the data collected in the SleepWellBaby app. None of the authors were involved in the development of the program.

Results

Participant Characteristics

A total of 1468 potential participants indicated an interest in the app and study. Of these, 798 (54.4%) participants met eligibility criteria and consented to participate, with 700 (87.7%) participants forming the baseline sample following completion of the baseline survey. Participants in the baseline sample who did not complete either follow-up survey at 7 days or 30 days (n=309) were excluded from subsequent analysis (Figure 1).

Of the final cohort included in the 7-day or 30-day follow-up analyses (n=391), most were mothers (n=382, 97.7%), with English as their main language (n=376, 96.2%), born in Australia (n=317, 81.1%), on leave from work (n=339, 86.7%), with a university education (undergraduate: n=152, 38.9%; postgraduate: n=151, 38.6%), in a long-term or married relationship (n=381, 97.5%), with an average age of 33.2 (SD 4.01) years. More than half (n=236, 60.4%) engaged with SleepWellBaby using an Apple device, 25.8% (n=101) used an Android, and the other 13.8% (n=54) were missing these data. Most of the included infants were born at term (n=369, 94.4%), 55.5% (n=217) were male, and most were being fed breastmilk (breastfeeding: n=348, 89% and/or expressed breast milk: n=113, 28.9%), with an average age of 2.6 (SD 1.7) months at baseline and age range spanning 0 to 5.9 months. This was the first child for most participants (n=280, 71.6%). The majority of participants lived in NSW (n=269, 68.8%), followed by Queensland (n=37, 9.5%), and Victoria (n=34, 8.7%). Most participants lived in major cities (n=316, 80.8%), followed by inner regional areas (n=62, 15.9%), then outer regional areas (n=11, 2.8%), with only one participant living in a remote or very remote area (n=1, 0.3%).

XSL•FO
RenderX

Figure 1. Recruitment and retention flowchart. EI: Engagement Index.

XSL•FO
RenderX

There were few statistically significant differences in demographics between those lost to follow-up after the baseline survey and those who continued to complete the 7-day and/or 30-day survey (Table 1). A greater proportion of those lost to follow-up were in full-time work (5.5% vs 1.8%; *P*=.03), and fewer were breastfeeding at baseline (83.5% vs 89%; *P*=.04). Fewer participants in the low-risk category (EPDS <10) were lost to follow-up than expected by chance; however, there was no statistically significant difference between the 2 groups in the mean baseline EPDS score or the other 3 parent well-being outcomes (Table 1). We determined that participants who remained in the study for analysis were sufficiently representative on the parent well-being outcomes of the cohort initially enrolled at baseline and a complete case analysis was conducted. As may be expected, both the 7-day and 30-day EI scores were significantly higher for participants included for analysis than participants lost to follow-up (Table 1).

Table . Baseline outcomes and Engagement Index for participants and participants lost to follow-up.

Baseline outcome and engagement index	All participants at baseline (n=700)	Participants included for analysis (n=391)	Participants lost to follow-up (n=309)	*P* value
Me as a Parent Score, mean (SD)	57.26 (7.93)	57.21 (7.72)	57.33 (8.21)	.83[a]
Fatigue Severity Score, mean (SD)	40.95 (9.33)	40.89 (8.96)	41.03 (9.80)	.84[a]

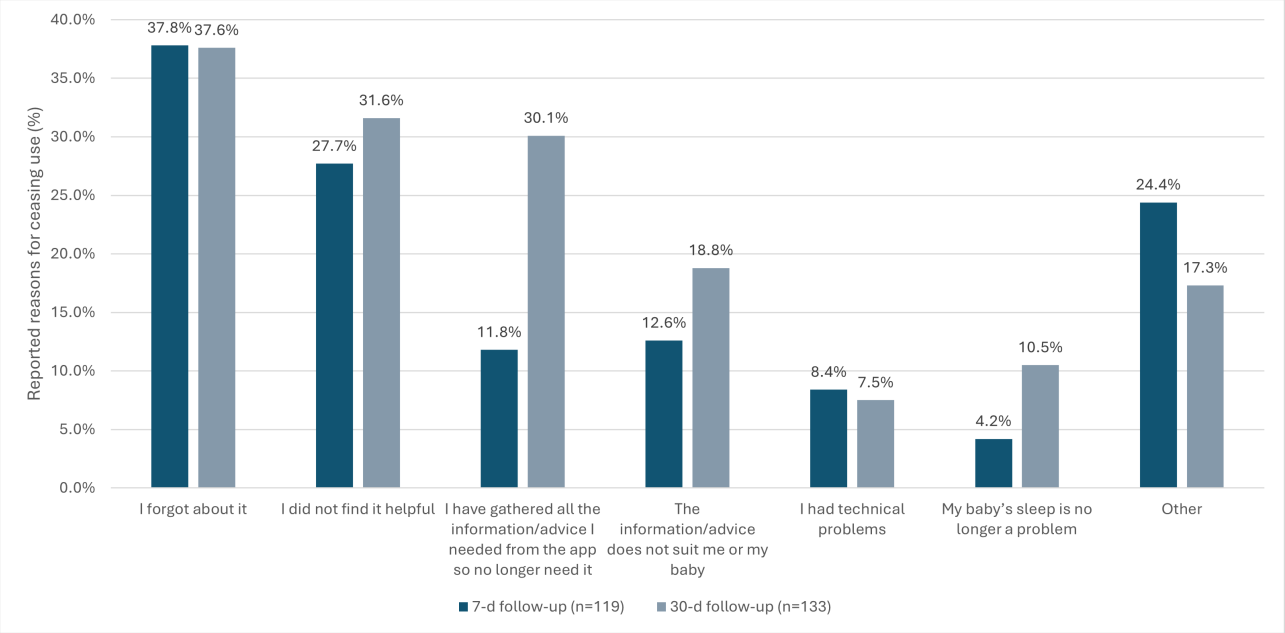
Engagement

Engagement with the program, based on the EI, was higher over the first 7 days (64.42/100), than at 30 days (60.06/100; t_{634}=16.842; P<.001). While the difference is small, it indicates participants used the program more in the first 7 days, compared to the first 30 days (Table 2).



Similarly, self-reported engagement based on the questions in the 7-day survey indicated decreasing use over time. At 7 days, 58.1% (n=227/391) of participants reported that they were still using the app regularly, while at 30 days, only 22.5% (n=88) were still using the app regularly. The most common reason for ceasing regular use was forgetting about the app, and the least common reason was that the infant's sleep was no longer a problem (Figure 2). Participants could provide an open-text response explaining their choice, which was incorporated into the thematic analysis. Responses were diverse as shown in these 3 examples of the open-text response: "Too overwhelming to have to log what my baby is doing. Don't want to continually have to look at the app P96"; "Missed a day and forgot! P127"; and It's tricky to use P1104."

Table . Engagement Index (EI) of app use by participants.

EI	7-d EI	30-d EI
Overall score		
Mean (SD)	64.42 (22.16)	60.06 (20.22)
Median (IQR)	65.14 (50.94 - 84.20)	61.14 (45.54 - 75.51)
Click depth (Ci)		
Mean (SD)	0.56 (0.26)	0.50 (0.26)
Median (IQR)	0.60 (0.40 - 0.75)	0.52 (0.33 - 0.69)
Loyalty (Li)		
Mean (SD)	0.80 (0.27)	0.85 (0.25)
Median (IQR)	0.90 (0.80 - 0.99)	0.93 (0.86 - 0.99)
Regency (Ri)

Figure 2. Reasons for ceasing use of the SleepWellBaby app.

Regarding perception of the program for help with infant sleep, most participants were either reported neutral perceptions or agreed that the program assisted with infant sleep (Table 3). There was a categorical change in perceptions between 7 days and 30 days (McNemar-Bowker test: χ^2_3=8.9; *P*=.03), with a shift from neutral to agree, indicating that more participants agreed that the program assisted with their infant's sleep at the 30-day follow-up than at the 7-day follow-up. Similarly, on the program helped parent sleep scale, there was a categorical change in perception between 7 days and 30 days (McNemar-Bowker test: χ^2_3=8.741; *P*=.03), indicating that more participants agreed that the program assisted with their sleep at the 30-day follow-up than at the 7-day follow-up.

Table . Perception of program impact on infant and parent sleep.

Item	Disagree, n (%)	Neutral, n (%)	Agree, n (%)	McNemar-Bowker test
Did SleepWellBaby help baby sleep?				.03
7-d follow-up	61 (16.5)	201 (54.3)	108 (29.2)	
30-d follow-up	34 (15.0)	103 (45.4)	90 (39.7)	
Did SleepWellBaby help parent sleep?				.03
7-d follow-up	109 (30.1)	176 (48.6)	77 (21.3)	
30-d follow-up	64 (28.3)	91 (40.3)	71 (31.4)	

Acceptability

For those participants who responded to the NPS question (n=306), 39.2% (n=120) rated the app 6 or less (detractors), 30.4% (n=93) rated it 7 or 8 (passives), and 30.4% (n=93) rated it 9 or 10 (promoters). The mean NPS was 7.05 (SD 2.48), indicating that most participants were satisfied with the program. However, based on the difference in the proportions of promoters and detractors, the overall NPS was −8.8% in this sample. On the other hand, the Parent Satisfaction Scale measured out of 50 showed an average of 36.26 (95% CI 35.60-36.93). The areas of language and trust scored the highest, while the areas of content and the sharing feature scored the lowest (Table 4).

There was a positive correlation between the EI and satisfaction score (Spearman ρ=0.52; *P*<.001), indicating those more highly engaged with the app reported higher satisfaction with the app. Whether engagement fostered satisfaction or whether satisfaction fostered engagement is not known. Subgroup comparisons for both the NPS and the satisfaction score found there was no difference in either scores based on baseline depression or anxiety symptoms, number of children, parent's education, or reported infant sleep problems (Multimedia Appendix 2), indicating that a diverse range of parents with varying characteristics found the program acceptable.

XSL•FO
RenderX

Table . Parent satisfaction scale at 7-d follow-up (n=330).

Area	Question	Mean (SD)	95% CI
Overall score (range 10 - 50)	__[a]	36.26 (6.17)	35.59-36.93
Language (range 1-5)	The language used in the app was easy to understand	4.25 (.623)	4.18-4.32
Trust (range 1 - 5)	I can trust the information on the SleepWellBaby app	4.19 (.650)	4.12-4.26
Notifications—amount (range 1 - 5)	I was happy with the number of notifications or email messages received each week	3.86 (.813)	3.77-3.95
Confidence (range 1 - 5)	I felt confident using this app	3.69 (.917)	3.59-3.79
Notifications—relevance (range 1 - 5)	I found the notifications or messages suited my baby's age and stage of development	3.58 (.840)	3.49-3.67
Notifications—content (range 1 - 5)	I found the notifications or email messages helpful	3.56 (.870)	3.47-3.65
Functionality (range 1 - 5)	The app did everything I expected it to do	3.41 (.967)	3.31-3.51
Content (range 1 - 5)	The SleepWellBaby program covered all of the things about sleep and settling that I wanted it to	3.16 (.999)	3.05-3.27
Feature—sharing (range 1 - 5)	I found it helpful to share the app with my partner/family	3.14 (1.009)	3.03-3.25

Open-Ended Text Response Findings

Overview

More than half (n=226, 57.8%) of the participants provided responses to the open-ended text response fields. Three themes were identified in these responses that were relevant to the acceptability of the program. These themes and their component parts are summarized in Figure 3. The themes are described in more detail below and illustrated with direct quotations from participants. Participants are identified with their self-identified carer role, age, and infant age (noting for those infants born prematurely, this is chronological age, not corrected age). Two additional themes identified in these qualitative responses focused on challenges with using and recommendations for improving the app interface. These themes related to the earlier version of the SleepWellBaby app used in the study and are therefore not included here.

XSL•FO
RenderX

Figure 3. Themes on acceptability from open-ended text response.

Theme 1: Lifeline

Responses grouped under this theme indicated satisfaction with the app and an experience of SleepWellBaby as a source of useful resources, information, and support. Participants shared that they found the program to be a helpful support for them as they navigated caring for their infant:

> *This app has helped me find out the sleep rhythm of my baby and taught me to build a sleep ritual which works well at the moment.*
>
> *[Participant ID 624, mother aged 31 years with infant aged 3 months]*
>
> *So great, it felt really personal as though I had someone supporting my journey with check ins and tracking.*
>
> *[Participant ID 312, mother aged 28 years with infant aged 4 months]*
>
> *Please keep it free, parents really need this support.*
>
> *[Participant ID 215, mother aged 31 years with infant aged 2 months]*

This support was noted particularly during time where access to physical services were limited during pandemic-related restrictions:

> *Love it! What a wonderful program which all parents should be able to access for free – particularly in lockdown. It is the lifeline we all need in the mindless and monotonous bedlam of baby sleep while spending so much time at home.*
>
> *[P628, mother aged 33 years with infant aged <1 month]*
>
> *The program and app have taught me so much in the early newborn phase that I feel so much more confident in my ability to manage without support as lockdown continues.*
>
> *[P1085, mother aged 32 years with infant aged <1 month]*

Theme 2: Mismatch

For some participants, however, there was a mismatch between what the program offered and their everyday experiences—they expressed that the routines or information provided did not suit. For some participants, this mismatch related to characteristics of their infant: the app was not appropriate due to factors such as prematurity, very young age, illness, or their infant's rhythm being different from the example routines. For others, it was related to their own dispositions, such as preferring another app or forgetting about the app:

> *It really didn't suit preterm babies—this could really be worked on.*
>
> *[P168, mother aged 31 years with infant aged 3 months (chronological age)]*
>
> *...it needed the chance to adjust for preterm babies. My child was 5 weeks preemie and programs are based on my child's actual age instead of corrected age.*
>
> *[P488, mother aged 31 years with infant aged 3 months (chronological age)]*
>
> *My baby is too young to start a routine.*
>
> *[P412, mother aged 35 years with infant aged <1 month]*
>
> *The program suggested felt a little unrealistic for my 1-month-old, and did make me feel a bit pessimistic.*
>
> *[P535, mother aged 36 years with infant aged 1 month]*

XSL•FO
RenderX

> *I don't find the app helpful if my baby is off schedule.*
>
> *[P211, mother aged 24 years with infant aged 2 months]*

Theme 3: Unintended Negative Effects

For some participants, features of the app—and, in some cases, the use of an app at all—were experienced as counterproductive, impacting negatively on their well-being, and making it more difficult to focus on being with their baby:

> *Tracking everything felt overwhelming.*
>
> *[P72, mother aged 35 years with infant aged 3 months]*
>
> *I find the information and the way it is presented very confusing.*
>
> *[P532, mother aged 35 years with infant aged<1 month]*

Some participants expressed that some features or use of the app added to their anxiety and sense of failure:

> *I found it was making me more anxious tracking sleep etc.*
>
> *[P78, mother aged 28 years with infant aged 5 months (chronological age)]*
>
> *My baby wasn't sleeping well and it made me feel much worse...the app made me feel I was failing.*
>
> *[P65, mother age not reported with infant aged 4 months]*

Other participants also noted that it contributed to increasing time on their phone, which was seen as undesirable:

> *I rarely ever was able to track in real time, [it] takes attention away from baby when they need it most.*
>
> *[P605, mother aged 32 years with infant aged 5 months]*

Impact on Parent Well-Being

Fatigue

Parents' engagement and self-reported perception of the program had a significant impact on parents' fatigue (FSS). In the final adjusted linear regression model, with all variables of interest included (model 4), 7-day engagement with the app decreased fatigue (Table 5). In this model, a 1-point increase in the 7-day EI score was associated with a decrease in FSS by 0.06 at 7-day follow-up. Similarly, the program helped parent sleep scale was also related to a decrease in FSS score, where a 1-point increase in agreement that the program helped with parent sleep was associated with a 1.7-point decrease at 7-day follow-up.

Fatigue at the 30-day follow-up was unrelated to the 30-day EI. However, in the final adjusted linear regression model (model 4), parent self-reported perception of the program was related to the FSS, where a 1-point increase in agreement that the program helped with infant sleep was associated with a 1.7-point decrease in FSS at 30-day follow-up.

XSL•FO
RenderX

Table . Impact of the engagement with app on fatigue, parenting confidence, and emotional health.[a]

Parent well-being outcome	7-d		30-d	
		P value		*P* value
Fatigue, adjusted FSS[b] (95% CI)				
Engagement Index	−0.06 (−0.1 to −0.01)	.01	0.02 (−0.05 to 0.09)	.63
Program helped infant sleep	0.41 (−0.93 to 1.76)	.55	−1.74 (−3.48 to −0.004)	.05
Program helped parent sleep	−1.72 (−2.95 to −0.48)	.007	0.81 (−0.96 to 2.49)	.34
Parenting confidence, adjusted MaaP[c] (95% CI)				
Engagement Index	0.03 (−0.01 to 0.06)	.11	0.02 (−0.04 to 0.07)	.57
Program helped infant sleep	1.48 (0.46 to 2.50)	.005	0.53 (−0.72 to 1.78)	.40
Program helped parent sleep	0.11 (−0.82 to −1.05)	.81	0.46 (−0.75 to 1.66)	.46
Emotional Health, adjusted EPDS[d] (95% CI)				
Engagement Index	0.00 (−0.02 to 0.02)	.97	0.01 (−0.02 to 0.04)	.69
Program helped infant sleep	−0.47 (−1.07 to 0.14)	.13	0.13 (−0.57 to 0.84)	.71
Program helped parent sleep	−0.18 (−0.73 to 0.38)	.53	−0.64 (−1.13 to 0.04)	.07
Emotional Health, adjusted GAD-7[e] (95% CI)				
Engagement Index	0.01 (−0.01 to 0.02)	.53	0.00 (−0.03 to 0.02)	.82
Program helped infant sleep	−0.34 (−0.89 to 0.20)	.22	0.15 (−0.49 to 0.79)	.64
Program helped parent sleep	−0.47 (−0.97 to 0.03)	.07	−0.48 (−1.10 to 0.14)	.13

[a]All models adjusted for parent age at baseline, infant age at baseline, parent education, number of children, pregnancy complication reported as baseline, baseline score of target outcome, and baseline score of the 3 other outcome variables.

[b]FSS: Fatigue Severity Scale.

[c]MaaP: Me as a Parent.

[d]EPDS: Edinburgh Postnatal Depression Scale.

[e]GAD-7: Generalized Anxiety Disorder-7.

Parenting Confidence

In the final adjusted linear regression model (model 4), neither the 7-day nor 30-day EI was related to the MaaP score (parenting confidence). However, the program helped parent sleep scale was related to the MaaP at the 7-day follow-up: a 1-point increase in agreement that the program helped with infant sleep was associated with a 1.48-point increase in MaaP at the 7-day follow-up. This demonstrates that participants who agree that the program is helpful for their infants' sleep have a measured improvement in their sense of competence, confidence, and self-efficacy as a parent.

Emotional Health

In the final adjusted linear regression model (model 4), parents' emotional health was not associated with engagement nor with self-reported perception of the program. Neither the EPDS nor GAD-7 scores at the 7-day or 30-day follow-up were related to the 7-day EI score or 30-day EI score (Table 5).

Discussion

Principal Findings

This study provides evidence of the engagement with and acceptability and impact of SleepWellBaby for Australian parents of infants. The SleepWellBaby program is suitable for many parents, and those who found the program useful experience statistically significant improvements in their fatigue and parenting confidence. Many of the participating parents engaged with the app, and the program was acceptable to most parents who provided feedback. Parents reported they were generally satisfied with the program. While acceptability and satisfaction were generally positive, there were some contrasting themes from the participants' open-text response feedback. Importantly, it was noted that the program may at times be mismatched to parent and/or child needs and could be counterproductive with unintended negative impacts on well-being.

Nevertheless, engagement with the program was associated with a statistically significant improvement in parents' fatigue. Parents who had higher engagement or found the program most helpful for their sleep and their infant's sleep showed the greatest improvement in their fatigue. The modeling found that

XSL•FO
RenderX

a 1-point increase (on a 100-point scale) in the 7-day EI score was associated with a decrease in parent fatigue severity (FSS) by 0.06 at 7-day follow-up. Given that a systematic review of patient-reported fatigue measures has identified minimum important difference for improvement for the FSS ranging from 0.08 to 0.4, this reduction is potentially clinically significant [47]. Similarly, parents' self-reported perception of the program to assist their own sleep at the 7-day follow-up was associated with a 1.72 decrease in FSS, and their infant sleep at 30-day follow-up was also related to improvement in fatigue with a 1.74 decrease. While these changes are modest, it demonstrates that participants who found the program helpful, and engaged more with the program, had measured improvement in their fatigue. Regarding the other outcomes of interest, there was no indication that engagement with the program had an impact on parents' emotional health where neither the EDPS nor GAD-7 scores at the 7-day or 30-day follow-up were related to the 7-day EI score or 30-day EI score. There was some indication that engagement with the program had an impact on sense of competence, confidence, and self-efficacy as parents' agreement that the program helped with infant sleep was associated with a 1.48-point increase in MaaP at the 7-day follow-up.

Engagement with the program was higher for the first 7 days, compared with the first 30 days, which aligns with the design of SleepWellBaby as a 7-day program that may be repeated as needed. For those who reported discontinued use of SleepWellBaby at 7-day and 30-day follow-up, few did so when their infant's sleep was no longer a problem. Around a third of participants had discontinued as they did not find it helpful, felt they had sufficiently gathered the information that they needed, or had simply forgotten about the app. This is similar to feedback from parents about other parenting apps [48] and suggests additional reminder features, such as push notifications, may be useful for supporting engagement. Another avenue of increasing engagement is increasing responsiveness of the app experience to user input or prompts that are based on the tracking data users enter into the app [49].

It is difficult to directly compare engagement with other similar apps due to the diversity of methods for measuring participant engagement [50]. Even among other studies using the same EI criteria, differences in the design and interactive features of each app impact the calculated EI. With this caveat in mind, compared to other studies using the EI criteria, engagement in the current study was similar or higher [24,48,51]. Likewise, the dropout of participants is similar to other evaluations of smartphone applications undertaken in the perinatal period [4,48,51,52].

While engagement and dropout in studies and evaluations of smartphone applications in the perinatal period are mixed, accessing parenting support and information via apps is increasingly popular [30]. A review of maternal and infant health smartphone applications in 2020 found 421 smartphone applications available, with 102 being 'evidence-based apps' as they were developed by a health care provider or affiliated provider [22]. There is a notable difference in parent use and engagement in 'commercial apps,' which are downloaded in the millions, and 'evidence-based apps,' which are downloaded in the thousands [53]. This may be due to marketing approaches and costs associated with keeping the application up to date with the smartphone operating systems. The risk in this market is that 'commercial apps' may not include the best, safest, most up-to-date evidence to support parents [30]. A solution may be partnership, as seen for SleepWellBaby, which combines commercial engagement strategies with evidence-based material [20].

While the NPS was negative in this sample, the 2025 12-month-to-date NPS for SleepWellBaby was 19 (email, November 24, 2025). Additionally, the adequacy of NPS as a standalone metric for use in healthcare has been questioned [54]. Therefore, we also included further questions related to satisfaction. On the basis of these, the program was acceptable to most, who were generally satisfied with the program and perceived most of the features as useful. However, some participants also expressed concerns that the program may at times be mismatched for their current needs and could be counterproductive, with unintended negative impacts on their well-being. One aspect of mismatch was the age and stage of development related to term versus premature infants. In the qualitative feedback, there was equivocal feedback regarding the suitability of the program for young infants (under 3 mo). Some parents did not find the tracking and sample plans realistic for their young infant, although others did. The Tresillian approach to infant and child sleep is child-led and responsive to child needs, and there is an emphasis on facilitating parents to observe, understand, and respond to their infant cues [31]. It may be that the nuance of this message is more difficult to convey via an app and may need additional educational resources (eg, videos).

One element within the theme *unintended negative effect* was that using digital technology made it harder for parents to focus on being with their baby. This tension around digital technology and parenting has been described elsewhere [55]. The parents in Facca's qualitative study described the usefulness of digital technology but felt some guilt about using these devices around their young children [55]. There is emergent research identifying different styles of engagement with apps among parents, such as those who tend to use detailed, consistent tracking and those who use basic, intermittent tracking [56,57]. For SleepWellBaby, tracking is just one feature of the program, and parents can choose not to use tracking while still using other features.

While tracking of infant sleep and daily routines can be a useful tool to identify patterns and routines, qualitative feedback from some parents indicated it was counterproductive to achieving their goals. A recent cross-sectional study on breastfeeding app use found that mothers who tended to use detailed, consistent tracking, compared to those using more basic, intermittent tracking, had higher psychopathological symptoms (eg, symptoms of depression or anxiety) [56]. However, as that was a cross-sectional study, the direction of effect is not clear—ie, whether tracking within the app triggered increased mood symptoms or whether mothers who already exhibited these symptoms were more likely to undertake detailed tracking. In the current evaluation, the EI measure did include app tracking elements in the interaction index, and there was no association between the EI and anxiety symptoms. However, any app that includes tracking in the perinatal period should be developed

XSL•FO
RenderX

in line with emerging evidence about any relationship between parental symptoms of depression or anxiety and app-based tracking [56].

Strengths and Limitations

A strength of this study was an open recruitment to sample across a general population of parents with minimal exclusion criteria. Yet, while there were limited restrictions on those eligible as the sample was self-selected, the demographic of recruited parents was skewed compared to the general parenting population toward women (mothers) who spoke English as the main language at home, mostly born in Australia, on parental leave from work, university educated, married or in a long-term relationship, and residing in a major city. While reflective of the general demographic of women who access residential parenting support services [14,58], it limits the applicability of these findings to parents with broader demographic characteristics, such as parents with lower educational attainment or those living in regional and rural locations.

The findings are also limited by the quasi-experimental pre-post study design. The lack of a control group and randomization limits the ability to identify the specific impact of the program. However, to offset this limitation, a strength of our analysis is the inclusion of EI, which is an objective measure of participant engagement with the app. Including EI within the models on impact provides some support that change in participant outcomes was related to participant use of the program. The potential for selection and response bias represents an additional limitation of this study. Participants were parents and carers who were motivated to use the SleepWellBaby app and willing to share their experiences and feedback, which may limit the generalizability of the findings. Most participants perceived their infant to have a sleep problem; however, this is unsurprising given the app's purpose of supporting parents to understand infant sleep and providing guidance on responsive sleep strategies. Although the proportion of participant loss to follow-up was comparable to that reported in other studies evaluating perinatal smartphone applications [48,52], attrition remained substantial. Participants who continued and those who did not were very similar in almost all baseline characteristics, although those participants who continued with the study were more highly engaged with the app; we therefore acknowledge the potential for overestimation of the effects of the SleepWellBaby app and limitation of generalizability of the results.

Finally, the evaluation was conducted during the COVID-19 pandemic, between April 2021 and March 2022. This period of data collection overlapped with several public health measures, including stay-at-home orders and limitations on in-person gatherings. There is growing evidence that the pandemic and associated public health measures were associated with poorer mental health outcomes for parents [59,60]. Notably, the NSW government provided funding to give free access to SleepWellBaby for NSW families during times during the pandemic when the strictest stay-at-home orders were in place (March to July 2020 and June to October 2021). Therefore, the findings need to be interpreted with this context in mind.

As noted, this sample was not particularly diverse and included mostly mothers. Few studies have included both parents [61]. One feature within SleepWellBaby is the ability to share with multiple users—however, data on the use of this feature was not collected in this evaluation. Therefore, further research could investigate the use of the program by both parents with a focus on this functionality. Importantly, any further research and evaluation should aim to recruit a diverse sample of parents to identify the efficacy and acceptability among a broader range of parents.

Conclusions

SleepWellBaby is an infant sleep digital smartphone app that offers a useful program suitable to many parents with infants. As is the case with many interventions, it is not one-size-fits-all—not all parents will find accessing early parenting support via an app helpful. Therefore, this is a useful program to be included within a suite of support options for parents, including non–mobile phone-based interventions. SleepWellBaby is available within the early parenting support structures provided in Australia, including primary health child and family services and intensive early parenting services, such as those provided by Tresillian Family Care Centres. Within this context, SleepWellBaby offers a unique accessible support option for many parents that can promote improved parental health and well-being through reduced fatigue and increased parenting confidence.

Acknowledgments

The authors would like to thank all the Tresillian and Sleepfit staff and managers and staff who supported this research, particularly Daniel Platt from Sleepfit for supporting data transfer and support with the app. The authors would also thank staff from Tresillian and Sydney Institute for Women, Children and their Families who supported recruitment. The authors acknowledge and thank all mothers, fathers, and carers who gave so generously of their time and shared their experiences and insights.

Funding

Both Tresillian (a not-for-profit NSW Health–affiliated organization offering a range of residential and outpatient programs for families) and Sleepfit solutions (private company that develops digital sleep programs for organizations) provided in-kind contribution to this research.

Abstract

Background: Digital technologies with breastfeeding content have become an important source of information for new parents in Germany. However, little is known about the content and quality of digital breastfeeding information sources.

Objective: The objective of this paper was to evaluate the scope, content, and quality of free-of-charge smartphone mobile apps and websites with breastfeeding-related content in Germany.

Methods: A cross-sectional study of mobile apps and websites was conducted in July 2023. The App Store for iOS and Google Play Store for Android were searched for mobile apps. Bing.de and Google.de were searched for websites. The quality, suitability of information, readability, and coverage of digital information on mobile apps and websites were evaluated. We used the user version of the Mobile Applications Rating Scale, the Health-Related Web Site Evaluation Form, the Suitability Assessment of Materials, and the Flesch Index tool, as well as a self-developed checklist. We report our results according to the STROBE (Strengthening the Reporting of Observational Studies in Epidemiology) statement.

Results: Eight mobile apps and 13 websites were included. The quality of information sources was generally good for apps (median 83%, IQR 73% - 87%) and websites (median 86%, IQR 83% - 89%). The suitability of information was good for apps (median 84%, IQR 70% - 89%) and websites (median 89%, IQR 78% - 94%). The coverage of information was good for apps (median 68%, IQR 59% - 86%) and websites (median 82%, IQR 73% - 100%). However, digital information was difficult or challenging to read on most apps (median 59%, IQR 53% - 68%) and websites (median 58%, IQR 47% - 61%). Seven of 8 mobile apps and 9 of 13 websites were commercial, with embedded links to shopping sites without external certificates confirming the trustworthiness of the information.

Conclusions: Assertive action from nonprofit and governmental institutions should be provided to support parents with reliable, unbiased, open-access digital breastfeeding information in Germany.

(JMIR Pediatr Parent 2026;9:e78128) doi:10.2196/78128

KEYWORDS

breastfeeding; mobile app; smartphone; German parents; internet; consumer health information; digital health literacy; content analysis

Introduction

According to the Health Information National Trends Survey (HINTS), approximately 70% of Germans prefer to get their health information from health care professionals, followed by internet research (21%) and friends or family (5%) [1]. However, the credibility of health information provided via an internet search was categorized as middle to low [1].

The most popular digital sources for obtaining perinatal and breastfeeding support are mobile apps, internet forums, and websites [2]. A 2017 survey of Belgian mothers found that more than 90% used the internet to seek information, with “breastfeeding” being the most frequently searched topic [3]. However, parents may be confronted with a large number of results when searching for terms such as “parenting,” which could lead to information overload [4,5]. With the rise in the use of smartphones came a rise in mobile health (mHealth) apps, defined as medical or public health practice supported by mobile

XSL•FO
RenderX

devices [6]. The willingness of parents to use mHealth apps in Germany appears to be high, as long as apps are free of charge [7].

Breastfeeding is associated with many short- and long-term health benefits for mothers and children. In Germany, 97% of infants are breastfed at birth, but this number drops to 73% by 2 months of life [8]. Digital tools may help to enhance breastfeeding success by providing information and motivation. Many mHealth-based interventions centering around pregnancy and breastfeeding have been developed in recent years and show potential to improve pregnancy care and increase breastfeeding rates and outcomes [9-13]. Alianmoghaddam et al [14] showed that online information about child nutrition and mobile apps can be a good option for breastfeeding promotion. However, in 2025, a systematic review and meta-analysis on the impact of mobile apps for breastfeeding found only a nonsignificant increase in the odds of exclusive breastfeeding, stating that there is insufficient evidence to show sustained beneficial effects on breastfeeding [15].

Information on the content and quality of digital breastfeeding information has been published in many countries, including the United States, Canada, China, Australia, Spain, and Italy [16-22]. Yet, little is known about the quality of digital breastfeeding information sources in Germany. The objective of this paper was to evaluate the scope, content, and quality of free-of-charge mobile apps and websites with breastfeeding information available in Germany.

Methods

Study Design

A cross-sectional study of German websites and mobile apps with breastfeeding content was conducted in July 2023. The App Store for iOS and Google Play Store for Android were searched for mobile apps. Bing.de and Google.de were searched for websites. We followed the STROBE (Strengthening the Reporting of Observational Studies in Epidemiology) reporting guideline, omitting items 13 and 15, which were not relevant for this study, as no study participants were recruited and no outcomes were measured [23].

Selection of Mobile Apps

The German App Store for iOS and Google Play Store for Android were screened with smartphones from July 19 to 20, 2023, by 2 reviewers (MZ, JP) using 9 search terms (see Table S1 in Multimedia Appendix 1).

Inclusion criteria for mobile apps were that mobile apps were offered free of charge, were in the German language, and contained information on breastfeeding. Exclusion criteria were restricted access, formatting as an electronic book (eg, e-books, news, magazines, podcasts, blogs, or word documents), games or gaming apps, and mobile apps whose main function was to monitor time or frequency of infant care tasks without providing educational information on breastfeeding.

Two reviewers (MZ, JP) independently screened all mobile apps for eligibility. For each search term, the first 10 mobile apps were selected, and features such as rating, costs, number of downloads, and characteristics of the mobile app were noted. A list of mobile apps was selected, duplicates were removed, lists for Android and iOS were jointly merged, and duplicates were removed again.

Evaluation of Quality, Suitability, and Readability of Mobile Apps

Three validated tools were used to evaluate mobile apps for quality, suitability, and readability. Each mobile app was reviewed independently by 2 reviewers (MZ, JP) and then evaluated using an evaluation form (see Multimedia Appendix 2).

To appraise the quality of mobile apps, the user version of the Mobile Application Rating Scale (uMARS) questionnaire in the original English language was used [24]. The uMARS is an established tool to assess the quality of mHealth apps rated by end users. It consists of 16 items, including 4 objective quality subscales (engagement, functionality, esthetics, and information), 1 subjective quality subscale, and a further subscale to measure the users' perceived impact of the evaluated mobile app [25]. All items were rated on a 5-point Likert scale (1=inadequate to 5=excellent) [24]. See Multimedia Appendix 2 for further information on the specific questions asked.

Suitability of information was assessed with the Suitability Assessment of Materials (SAM) questionnaire, which was validated by students and health care providers from several cultures [26,27]. It rates health-related materials in 6 areas (content, literacy demand, graphics, layout and type, learning stimulation and motivation, and cultural appropriateness). There are 22 questions on a 3-point scale (0=not suitable, 1=adequate, 2=superior). For missing items, the instructions of the SAM were followed. For questions answered as not applicable, 2 points of the possible 44 points were subtracted. Suitability was rated based on scoring (0% - 39% suitable material, 40% - 69% adequate material, and ≥70% superior material). The suitability for a particular population was ranked from 0 (not recommended) to 10 (recommended without reservations) based on socioeconomic and cultural backgrounds of the population [27].

Readability was rated with the Flesch Index online tool, which provides a score from 0 to 100 (0 - 30: hard to read, 30 - 50: difficult to read, 50 - 60: challenging, 60 - 70 normal, 70 - 80: easy to read, 80 - 90: easily to read, 90 - 100 very easy to read) [28]. As the Flesch Reading Ease test was developed for the English language, it needed to be adapted for the German language [29]. For the evaluation, 3 randomly chosen paragraphs were copied into the online tool and the average of the Flesch Reading Ease test results was used for evaluation.

Search Terms for Websites

Websites were identified using Google.de and Bing.de between July 13 and 17, 2023 [30,31]. Google Trends and Ubersuggest were used to identify appropriate search terms [32,33]. Google Trends is a tool to get information about how often users of Google enter explicit search terms. Ubersuggest is a tool to analyze keywords, find ideas for new keywords, and give insights into the ranking of the keywords.

XSL•FO
RenderX

A layperson was asked to suggest how to search for breastfeeding information and problems. These terms were used to find the most popular search terms for this topic on Ubersuggest and Google Trends for Germany. Twelve German search terms were used (see Table S2 in Multimedia Appendix 1). Before screening each search term individually, the search history and cookies were deleted to simulate the first search of a layperson. For each search term, the first 10 links were selected, as consumers rarely read beyond the first page of search results [34].

Selection of Websites

Two reviewers (MZ, JP) independently screened all websites for eligibility. Search terms used were identified and recorded for each website. Websites with only 2 or fewer of the selected search terms were excluded. The 2 lists from Google and Bing were compiled, and duplicates were removed. Inclusion criteria comprised use of the German language and breastfeeding content. Websites inaccessible because of dead or broken links, websites formatted as PDFs, commercial websites, social media platforms (eg, Facebook), and websites without breastfeeding content were excluded.

Evaluation of Quality, Suitability, and Readability of Mobile Websites

Three validated tools were used to evaluate websites for quality, suitability, and readability. Each website was reviewed independently by 2 reviewers (MZ, JP) and then evaluated using an evaluation form (see Multimedia Appendix 3).

To appraise the quality of information, the Health-Related Web Site Evaluation Form (HRWSEF) was used [35]. The HRWSEF is an evaluation instrument for health educators and clinicians to evaluate the appropriateness of health education websites for clients and patients. It is a 36-item tool including 9 topics (website information, content, accuracy, author, currency, audience, navigation, external links, and structure). Users judge (1=disagree, 2=agree, 0=N/A) whether the website is a good source of information for the patient or whether it should not be recommended. Instructions of the HRWSEF questionnaire were followed for missing information (questions which were not applicable were deleted from the total scoring). Therefore, the total number of points depended on the number of questions answered with “agree” or “disagree.” Quality was rated based on scoring (0% - 74.9% poor quality, 75% - 89.9% adequate quality, and ≥90% excellent quality) [35].

As for mobile apps, suitability of information was assessed with the SAM questionnaire, and readability was assessed using the Flesch Index online tool [27,28]. The readability of the selected website was evaluated by copying 3 links of a paragraph of the sites hit by the search to the online tool, and the average of the Flesch Reading Ease test results was used for evaluation.

Coverage of Information

To assess the coverage of information, 11 basic breastfeeding topics were used, based on the guidelines of the German Healthy Start–Young Family Network [36]. The websites and mobile apps were screened independently by 2 reviewers with technical nutrition and lactation expertise for coverage of the 11 topics (MZ, JP). If the 2 reviewers had a different outcome, the websites and mobile apps were screened again to achieve consensus. The 11 items are listed in the 2 standardized self-developed checklists (see Multimedia Appendix 3 for the apps and Multimedia Appendix 3 for the websites). All items on the checklists were dichotomously answered (yes/no). Then 11 items were summed and converted into percentages for descriptive statistics.

Statistics

Interrater reliability (IRR) testing was undertaken between the 2 reviewers assessing mobile apps and websites by comparing scores from each rating tool. The IRR agreement was assessed using the Kendall coefficient of concordance (Kendall rank correlation coefficient) for ordinal variables [37].

The scores for mobile apps and webpages were summarized using boxplots for each index, where the scores for each index were transformed into percentages to plot all indexes in one plot. Medians and IQR (25th and 75th percentiles) were calculated. Kendall τ correlation was used to examine correlations between Google Play Store ratings, App Store ratings, and the different uMARS scores, Flesch Index, and SAM questionnaire. Values from the 2 app stores were summarized by calculating means. A 2-sided P value <.05 was considered statistically significant. All analyses were performed using R Studio version 4.3.2 (R Foundation for Statistical Computing, Vienna, Austria) [38].

Results

Eight mobile apps and 13 websites with breastfeeding-related content were identified.

German Mobile Apps With Breastfeeding Content

The selection process describing the numbers of mobile apps identified at each stage of the selection process is displayed in Multimedia Appendix 1. A description of all included mobile apps is given in Table 1.

XSL•FO
RenderX

Table . Description of included mobile apps (n=8).

Name of the app	Published by	Authors	Category	Average user rating on App Store/Google Play Store (range 0 - 5)	Downloads in Google Play Store	Comment
Preglife, Schwangerschaft app	Preglife - Swedish health care company	Midwives, lactation specialists	Medicine	4.9/4.5	>1 million	Breastfeeding information, tracker, mum workouts, meditation, diary, reduction codes for companies
Medela Family - Stillen Tracker	Medela AG - Company distributing products for breastfeeding	Mostly not characterized, midwives and self-called Medela breastfeeding experts	Medicine	4.1/4.5	>500,000	Breastfeeding information, tracker, shop, chatbot, connection to personal pump
Baby+/Dein Baby-Tracker	Philips in collaboration with Health & Parenting	Not specified	Medicine	4.6/4.6	>5 million	Breastfeeding information, tracker, lullabies, diary, and documentation of sentimental milestones
Baby & Essen	Federal Agency of Agriculture and Nutrition	Agronomist, ecotrophologist	Foods + drinks	4.4/3.9	>100,000	Breastfeeding information, mode for fathers, and diary
Keleya: Still- & Beckenboden app	Keleya Digital Health Solutions GmbH	Midwives, breastfeeding counselors, breastfeeding expert	Medicine	4.8/3.5	>5000	Breastfeeding information, meditation, gymnastics, and breastfeeding preparation online courses
Hipp Baby app	HIPP GmbH - food producer	Breastfeeding counselors, midwives, medical educator	Lifestyle	4.4/2.2	>500,000	Breastfeeding information and map to find places for breastfeeding, and changing diapers among others
BabyCare-Gesund & Schwanger	Pregive GmbH - independent research institute	Physicians, midwives	Medicine	4.5/4.7	>10,000	Breastfeeding information, recipes, quizzes, relaxation music, gymnastics, among others
ELTERN - Schwangerschaft & Baby	G+J Medien GmbH - media Publisher	Mostly not characterized, nonspecialized journalists	Medicine	4.6/4.3	>100,000	Breastfeeding information, community, and documentation of sentimental milestones

All included mobile apps were free of charge; however, for some mobile apps, upgrades were available that required a fee. The average user rating of mobile apps ranged from 3.3 to 4.7 (out of 5, with 1 being the lowest and 5 being the highest rating). The Google Play Store showed download numbers ranging from more than 5000 to more than 5 million, whereas no such information was available in the App Store for iOS. Six out of 8 mobile apps were found in the stores under the category “Medicine,” one under “Lifestyle,” and one under “Foods + Drinks.” One mobile app (Baby & Essen) was provided by a governmental agency; all others were commercial in nature.

Included mobile apps not only provided informational content but also other features (eg, 3 apps had a tracker for tracking diapers, breastfeeding meals, and sleeping).

For 3 of the included mobile apps, it was not clearly stated whether health professionals wrote the text. None of the identified mobile apps showed any certification to prove independent and correct health information or had a data protection certification.

The mobile app with governmental affiliation showed no advertisements, whereas all others were commercial in nature. Six commercial mobile apps showed advertisements for

XSL•FO
RenderX

breastfeeding-related products (eg, pumps, creams, bottles and teats, pacifiers, formula, and supplements) or linked wording within the texts to websites for ordering products. One mobile app (Preglife) showed general family-related advertisements.

There were only 4 mobile apps offering content in a language other than German. The mobile app Baby+ is available in 18 other languages (eg, Turkish, Polish, Russian, and English), the mobile app Keleya: Still- & Beckenboden offers content in the English language as well, Medela in 11 other languages (eg, Russian and English), and Preglife in 9 other languages (eg, Polish and English).

Evaluation of Quality, Suitability, and Readability of Mobile Apps

The quality of the selected mobile apps using the uMARS index ranged from 3.4 to 4.6 (out of 5), with a median of 4.1 (out of 5) (83% [IQR 73% - 87%]). However, the mobile apps differed more in the perceived impact of the uMARS, ranging from 23% to 93%.

The suitability of information showed a median of 84% (IQR 70% - 89%), whereas all mobile apps reached at least half of the points in the suitability for population, and some reached the total of 10 points (Medela, Baby+). The median of the Flesch Index was 59% (IQR 53% - 68%), which is around half of possible points to reach (Figure S3 in Multimedia Appendix 1).

The ratings of the subjective uMARS index and the store rating by the users were correlated (Kendall τ=0.67; P=.03). There was no statistically significant correlation between any of the other scores. Detailed evaluation results of all included mobile apps are given in Table 2.

Table . Evaluation results of included mobile apps (n=8).

Name of the app	uMARS[a] quality mean score (range 0 - 5; %)	uMARS subjective quality (range 0 - 20; %)	uMARS perceived impact (range 0 - 30; %)	Suitability of information (SAM[b]; range dependent 0 - 44; %)	Suitability for population (SAM; range 0 - 10; %)	Coverage of information (range 0 - 11; %)	Flesch index (range 0% - 100%)
Preglife, Schwangerschaft app	4.6 (92)	16 (80)	25 (83)	27/30 (90)	8 (80)	9 (82)	57
Medela Family - Stillen Tracker	4.4 (88)	13 (65)	28 (93)	30/34 (88)	10 (100)	11 (100)	52
Baby+/Dein Baby-Tracker	4.3 (86)	14 (70)	18 (60)	23/32 (72)	10 (100)	7 (64)	69
Baby & Essen	4.2 (85)	12 (60)	24 (80)	22/26 (85)	7 (70)	8 (73)	67
Keleya: Still- & Beckenboden app	4 (80)	13 (65)	22 (73)	34/38 (90)	9 (90)	7 (64)	53
Hipp Baby app	3.7 (73)	5 (25)	12 (40)	31/38 (82)	6 (60)	6 (55)	61
BabyCare-Gesund & Schwanger	3.6 (73)	13 (65)	7 (23)	12/20 (60)	5 (50)	4 (36)	46
ELTERN - Schwangerschaft & Baby	3.4 (68)	6 (30)	14 (47)	23/30 (68)	6 (60)	10 (91)	71

German Websites With Breastfeeding Content

The selection process describing the numbers of websites identified at each stage of the selection process is displayed in Multimedia Appendix 1. A description of all included websites is given in Table 3.

XSL•FO
RenderX

Table . Description of included websites (n=13).

Name and information of the website	Link	Certification	Authors
Familie, the website of a media brand financed with advertisement	[39]	No	Nonspecialized journalists
Kindergesundheit-Info, Federal Center for Health Education	[40]	No	Not characterized
Babelli, a company participating in partner and advertisement program of Amazon.de financed with advertisement	[41]	Certificate of the Health Foundation	Nonspecialized editors, content checked by midwives and a lactation consultant
Team Muttermilch, the website of an IBCLC[a] and pediatrician to inform and sell services	[42]	No	Individual lactation consultant
Medela, a company distributing products for breastfeeding	[43]	No	Mostly not characterized, midwives and self-declared breastfeeding experts
Wikipedia, encyclopedia	[44]	No	Not characterized
Netdoktor, information about health and medicine topics financed with advertisements	[45]	Afgis certification	Physicians, biologists, specialized journalists
Still-Lexikon, information about breastfeeding financed with advertisement and donation	[46]	World Health Organization conformity	Individual bioscientist, journalist, lactation consultant
Eltern, the website of the eponymous journal	[47]	No	Mostly not characterized, nonspecialized journalists
Lansinoh, a company distributing products for breastfeeding	[48]	No	Not characterized
Apotheken Umschau, the website of the eponymous journal	[49]	Afgis certification; certificate of the Health Foundation	Not characterized
Hipp, a company distributing food products for babies and toddlers	[50]	No	Breastfeeding counselor
Windeln, a company selling baby products and a magazine	[51]	No	Mostly not characterized, midwives

[a]IBCLC: international board certified lactation consultant.

Four websites referred to companies selling baby products (Medela, Lansinoh, Hipp, Windeln), 3 referred to parenting or health-related magazines (eg, Eltern, Apotheken Umschau, Windeln), and 1 referred to a media brand (Familie). Of the 4 informational websites, only 1 had a government affiliation (Kindergesundheit-Info). One website was an encyclopedia (Wikipedia), and 1 referred to a mobile app (Babelli).

Seven websites did not specify which professional group wrote the texts, and only 2 websites provided content written by breastfeeding experts. One of the included websites showed a quality logo (afgis), one the certification of the Stiftung Gesundheit, and one other showed both; thus, less than a quarter of the websites had a quality of information certification.

Eight websites showed advertisements for breastfeeding-related products (eg, pumps, creams, bottles and teats, pacifiers, formula and an infant flatulence product) with a direct link to order these products. Two websites showed no advertisements (Wikipedia, Kindergesundheit-Info), 2 websites showed general advertisements (Still-Lexikon, Apotheken-Umschau), and 1 showed advertisement for a breastfeeding book and consultation (Team Muttermilch).

Evaluation of Quality, Suitability, and Readability of Websites

The quality of the selected websites showed a median HRWSEF of 86% (IQR 83% - 89%). The suitability of information varied between 64% and 100%, with a median of 89% (IQR 78% - 94%). The suitability for the German population was rated between 5 and 10 out of a maximum of 10 points, with 5 websites being recommended to the German population without reservation (Familie, Team Muttermilch, Medela, Lansinoh, Apotheken Umschau). The median of the Flesch Index was 58% (IQR 47% - 61%), which is around half of the possible points to reach (Figure S4 in Multimedia Appendix 1). Detailed evaluation results of all included websites are given in Table 4.

XSL•FO
RenderX

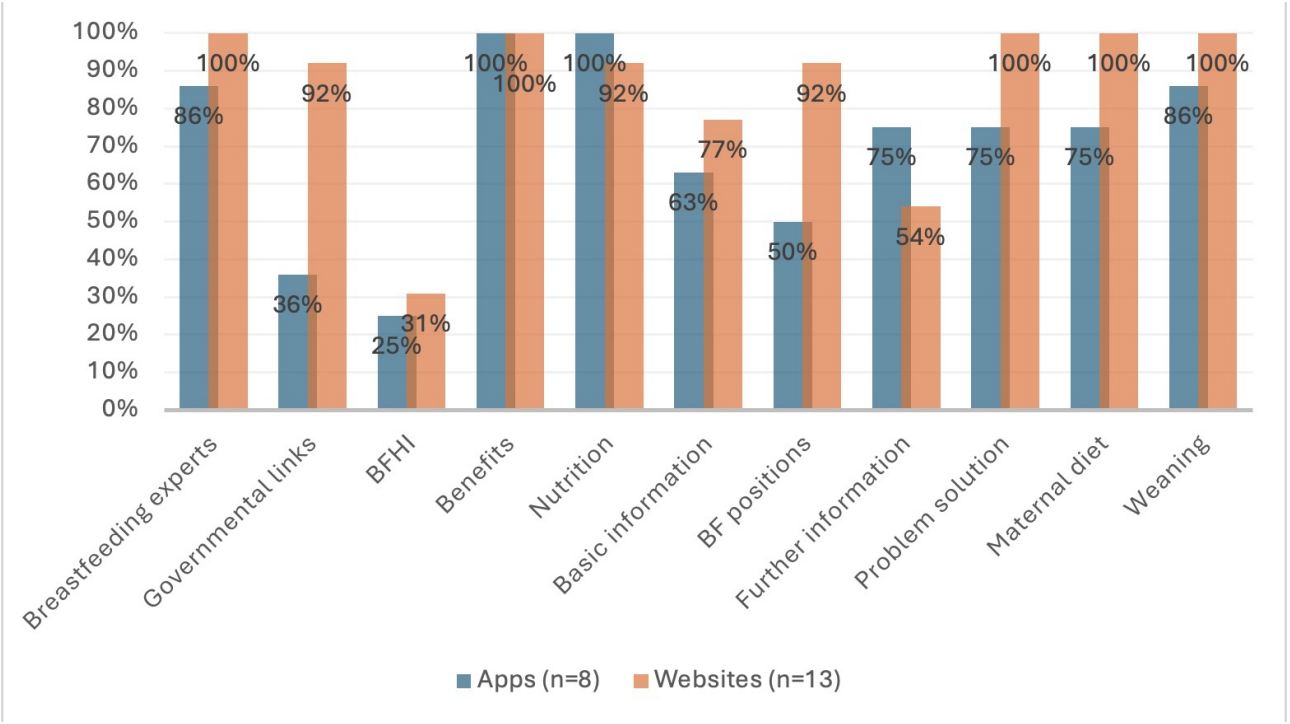
[a]HRWSEF: health-related web site evaluation form.

[b]SAM: suitability assessment of materials.

[c]IBCLC: international board certified lactation consultant.



Coverage of Information

The mobile apps reached at least half of the points in the coverage of information (except Baby Care Gesund & Schwanger), and only 1 mobile app reached the total points (Medela) (Table 2). The coverage of information for the analyzed websites ranged between 8 and 11 (out of 11 items), with almost one-third reaching the maximum total points (Table 4).

The results for coverage of information show that websites provided more information for many topics than mobile apps (Figure 1).

XSL•FO
RenderX

Figure 1. Coverage of basic breastfeeding topics within the mobile apps and websites. BF: breastfeeding; BFHI: Baby-Friendly Hospital Initiative.

Three companies (Medela, Eltern, Hipp) offered both a website and a mobile app. Some differences between mobile app and website content were identified. Website content was of higher quality, suitability of information, and coverage of information, and was easier to read compared with the app from the same company (Table S4 in Multimedia Appendix 1).

Statistics

IRR testing between the 2 reviewers assessing all selected mobile apps and websites showed a Kendall coefficient of concordance values of 0.92 for mobile apps and 0.90 for websites (P<.01) (Tables S5 and S6 in Multimedia Appendix 1).

Discussion

Principal Findings

This is the first cross-sectional study of mobile apps and websites with breastfeeding content in Germany. The 8 apps scored a median of 4.1 (out of 5) on the uMARS scale, indicating good quality. Three of 13 websites were rated as excellent (3/13, 23%), and 10 of 13 as adequate quality (10/13, 77%) as per the HRWSEF. Four of the 8 mobile apps (4/8, 50%) and 9 of 13 websites (9/13, 70%) were rated as difficult or challenging to read based on the Flesch Index. Websites provided more comprehensive information coverage based on the checklist, with a median of 9 of 11 (IQR 8 - 11) topics covered. This was slightly more than mobile apps, which had a median 7.5 of 11 (IQR 6.5 - 9.5) topics covered.

Only 1 mobile app and 1 website had a governmental affiliation, whereas all other websites and mobile apps were commercial in nature. Most mobile apps (6/8, 75%) and websites (8/13, 62%) displayed advertisements for breastfeeding-related products. Only a minority of mobile apps (4/8, 50%) and websites (2/13, 15%) offered content written exclusively by medical and allied health professionals. We found the number of available commercially developed mobile apps and websites written by nonprofessionals to be concerning, since they can potentially provide biased or inaccurate information to parents.

Quality of Mobile Apps and Websites

Overall, we found that German mobile apps with breastfeeding content were of average to good quality based on their mean uMARS quality scores. Findings from studies in other countries that reviewed infant-feeding and pregnancy mobile apps rated the majority as poor or moderate quality [17,20,52,53]. Only 1 review rated 16 parenting mobile apps as good or excellent [18].

Compared with those studies, our reviewer ratings were typically higher for items included in the uMARS objective score than the subjective score. According to our findings based on the subjective uMARS scale, we would not recommend 2 of the 8 mobile apps (2/8, 25%). In addition, we would only recommend 5 mobile apps (5/8, 63%) with reservations. Only 1 mobile app had a high recommendation score (Preglife; Table S3 in Multimedia Appendix 1). Our findings align with Cheng et al [20] and may reflect reviewer bias, as most apps (7/8, 88%) were commercial. Given that the reviewers were health professionals trained in recognizing the effects of advertisements on health behavior, their positionality may have influenced the scoring. Specifically, commercial apps may have received lower ratings because of the reviewers' awareness of how marketing strategies can shape consumer choices and health outcomes. A review of Virani et al [18] found that commercial parenting apps were more popular than governmental, likely because they are more visually appealing and entertaining. Apps that offer additional features, such as trackers, receive higher user ratings—an increase of 27% for each added feature [54]. However, monitoring and tracking breastfeeding seems to be the least effective way to improve breastfeeding outcomes [55].

XSL•FO
RenderX

Three websites were rated as excellent, and 10 as adequate quality. The selected German websites were of much better quality than those reviewed in previous studies [52,56].

The majority of mobile apps and websites received high ratings for health information, while a smaller proportion was deemed adequate. Previous evaluations reported lower scores, indicating that the quality of these resources has presumably improved in recent years [20,52,56].

Suitability for Population and Readability

Germany is ethnically diverse, with about a quarter of the population having a migration background [57]. In contrast to a review of Australian apps and websites, adequate suitability for population was considered for about half of the reviewed mobile apps and websites in our study [52].

Three-quarters of the websites and half of the mobile apps in this study were considered challenging or difficult to read and understand. A high literacy level is required to understand the content of many mobile apps and websites [20,52,56]. A previous survey in Germany found that 23% of the interviewed persons (n=2902) said the health information provided verbally or written was difficult to understand [1]. For example, print materials and health mobile apps for weight loss could be improved by using simpler language [58]. Apps that are only available in German could at least be improved by using a lower level of literacy if they aim to reach non-native German speakers. Turkish, Polish, Russian, and Syrian people are the largest immigration groups in Germany [57]. The mobile app Baby+ is available in 18 other languages, which is likely the reason it has the most downloads.

Mobile App and Website Authors

Three of 8 apps and 7 of 13 websites provided insufficient information about the qualifications of their authors. In Germany, titles such as “breastfeeding counselor” or “breastfeeding expert” are not certified professions, whereas “International Board Certified Lactation Consultant” (IBCLC) is protected [59]. Among the websites and apps included in this study, only 3 websites and no mobile app were authored by IBCLCs. From the perspective of parents, Hughson et al [12] claimed that users prefer mobile apps that come from a trusted source, whereas Biviji et al [16] found little concern among the users about evidence-based content. Helpful online breastfeeding support can increase the likelihood of breastfeeding [60], but breastfeeding-related advice and information that is potentially produced by unqualified health professionals or lay persons or without clear authorship is concerning.

Coverage of Evidence-Based Content

Content that is not evidence based is harmful because it may spread myths, outdated or inaccurate advice, or contradict current public health recommendations, potentially increasing parental confusion and negatively affecting breastfeeding rates. Additionally, there is a lack of standards for the development of health apps [61]

Our results match previous findings stating that the coverage of information in mobile apps and websites is poor and partially contrary to Infant Feeding Guidelines [19,20,52,53,56]. When screening the apps and websites, the uMARS referred to the quality of information asking “Is app content correct, well written, and relevant to the goal/topic of the app?” (see Multimedia Appendix 2, app evaluation form), and the HRWSEF referred to accuracy asking “The information is accurate” (disagree, agree, or not applicable; see Multimedia Appendix 3, website evaluation form). However, as the user instruction for these tools suggests browsing the website(s) for a few minutes and the app(s) for at least 10 minutes (see Multimedia Appendix 2 and Multimedia Appendix 3), it is not possible to view the complete content. The rating of these questions is therefore based on the content assessed. To highlight the importance of evidence-based information, based on the German guidelines of the German Healthy Start-Young Family Network by the Federal Center for Nutrition, the authors used the self-developed checklist for coverage of information.

Advertisements Within Mobile Apps and Websites

Of the 13 websites reviewed, 8 linked directly to shops for breastfeeding products or breast-milk substitutes or displayed related advertising. One site (Babelli), which claims to be certified by the Health Foundation, linked to welcome gifts from companies producing breast-milk substitutes. Three apps directly referred to companies promoting their own products (Baby+, Hipp, Medela), and 3 others displayed advertisements for breastfeeding-related products or linked parts of their text to online shops. In our view, information intended to support breastfeeding should not include advertising for breast-milk substitutes. Nevertheless, manufacturers use digital platforms to combine breastfeeding information with marketing [62,63]. The International Code of Marketing of Breastmilk Substitutes of the World Health Organization [64], European Union legislation on infant formula [65], and German legislation on infant formula [66] all stipulate that there should be no advertising or other form of promotion of infant formula to the general public. The World Health Organization recently published technical guidance on regulatory measures to restrict digital marketing of breast-milk substitutes [67]. Until now, Germany has only adopted some of the provisions of The International Code; therefore, information on follow-on formula is permitted to be advertised to the general public [68].

Certification

Several certificates for quality of health-related websites exist in Germany, including Action Forum Health Information System (afgis) [69], Stiftung Gesundheit (Health Foundation) [70], and the medical search machine for German-speaking countries (Medisuch) [71]. The HONCode (Health on the Net Foundation) [72] was a reliable certification for ethical and qualitative standards of websites with health-related topics. Although it stopped its service in 2022, some websites still showed the certification at the time of our search. Only 3 websites were certified, and not even a quarter of the websites had any proof for correct medical information.

Strengths and Limitations

One strength of this study is that the quality appraisal of websites and mobile apps was performed using a variety of validated tools.

XSL•FO
RenderX

The scope of this study was limited to mobile apps and websites with breastfeeding information available in German. Therefore, the findings of this study are not generalizable to websites and mobile apps in other languages.

This study focused on free-of-charge mobile apps, which are used most often. It is plausible that higher quality information might be available on breastfeeding mobile apps that charge a fee. Some health insurance companies offer a mobile app for pregnancy or parenthood with breastfeeding content "free of charge," but these are only available to their insured members through app stores. Our mobile app search did not include mobile apps provided by health insurance companies. Due to the possibility of using Google Trends and Ubersuggest, the selection of websites involved more differentiated search terms compared to mobile apps. This might have increased the likelihood of selection bias.

Conclusion

The reviewed apps and websites were generally of acceptable quality, but many included advertisements for breast-milk substitutes. Credible health authorities should improve visibility through effective keywords, regular updates, and content authored by qualified professionals. Independent certification for noncommercial, accurate health information is needed, and all content should follow relevant guidelines. Texts should be motivating, easy to read, and supported by summaries, visuals, and videos to aid users with limited time or literacy. To reflect diverse populations, providers should use inclusive images and offer translations into commonly spoken languages.

Features such as breastfeeding support, meal and sleep tracking, quizzes, recipes, milestone documentation, and chat functions may enhance user engagement and app ratings and could be integrated by public actors when designing evidence-based health apps.

In conclusion, although current evidence is insufficient to demonstrate sustained beneficial effects of breastfeeding promotion and support on breastfeeding rates through mobile apps alone [15], integration of evidence-based educational content in mobile apps together with personalized remote support nonetheless holds potential to improve breastfeeding outcomes [55,73].

Acknowledgments

We would like to thank Julia Papst for reviewing the apps and websites. We would like to thank Frances Strobl for providing comments and copyediting.

Funding

This work was financially supported in part by the Child Health Foundation (Stiftung Kindergesundheit, www.kindergesundheit.de), Munich and the German Federal Ministry of Education and Research (Bundesministerium für Bildung und Forschung, BMBF) as part of the German Center for Child and Adolescent Health (DZKJ), 01GL2406A. BVK is the Else Kröner Seniorprofessor of Pediatrics at LMU–University of Munich, financially supported by the charitable Else Kröner-Fresenius-Foundation, LMU Medical Faculty and LMU University Hospitals.

Conflicts of Interest

MZ, VJ, and MAT report no conflicts of interest. BVK has received reimbursement for speaking at conferences supported by companies marketing nutritional or healthcare-related products and by not-for-profit biomedical associations including the American Academy of Pediatrics, European Academy of Pediatrics, Biomedical Alliance in Europe, United European Gastroenterology, German Society for Pediatrics and Adolescent Medicine, and German Professional Association for Gynecology and Obstetrics.

Abstract

Background: Digital interventions offer a promising avenue for scalable parenting support in low- and middle-income countries, where in-person coverage remains limited. However, engagement disparities may reduce their potential for population-level impact.

Objective: This study examined caregiver-level predictors of engagement with ParentApp, a smartphone-based adaptation of the Parenting for Lifelong Health (PLH) for Teens program for caregivers of adolescents aged 10 to 17 years.

Methods: This study was nested within a cluster-randomized factorial trial of ParentApp in Mwanza, Tanzania, implemented according to the optimization phase of the Multiphase Optimization Strategy. Clusters (n=16), comprising 614 caregivers (n=205, 33.4% men), were randomized to 3 components: guidance (guided vs self-guided), app design (unstructured vs structured), and digital support (enhanced vs basic). Digitally tracked app engagement outcomes included the number of modules completed, the first module not started, and the first module not completed. Baseline candidate predictors included demographic, socioeconomic, behavioral, and psychological factors assessed via an app-embedded questionnaire. Poisson generalized linear mixed-effects models with random effects for clusters assessed associations between predictors and each outcome. Interaction terms were specified to test whether associations differed by caregiver gender.

Results: Among 614 caregivers, 596 (97.1%) completed the first module; however, engagement declined rapidly thereafter, with only 281 (45.8%) completing module 2 and 49 (7.9%) completing all 12 modules. Overall, mean content completion was 35.6% (SD 33.1%) of the program. Women completed approximately 15% more modules than men (incidence rate ratio 1.15, 95% CI 1.05-1.27, P=.003), despite reporting higher levels of financial stress, food insecurity, child maltreatment, and depressive symptoms at baseline (all P≤.02; Cohen d=0.19 - 0.37). No other caregiver characteristics were significantly associated with engagement.

Conclusions: This is the first known study to investigate caregiver-level predictors of engagement with a digital parenting intervention in a low- and middle-income country. Engagement with ParentApp was broadly consistent across caregiver subgroups, with the exception that women completed significantly more modules than men. To equitably engage men and fathers, future studies should pair father-inclusive, identity-affirming content with implementation strategies that reduce social and economic barriers to participation.

KEYWORDS

digital health; mobile phone; parenting; violence against children; predictors; engagement; low- and middle-income countries

Introduction

Parenting interventions are central to global efforts to prevent violence against children and promote family well-being [1,2]. However, access to evidence-based parenting support remains limited in many low- and middle-income countries (LMICs). Workforce shortages and the high costs of in-person delivery restrict service availability, while travel, time, and competing work and caregiving responsibilities make it difficult for many families to participate [3,4]. Promisingly, there is growing evidence that digital parenting interventions can improve parenting and child outcomes, including among hard-to-reach families in LMICs [5,6]. However, program effects are often small and user engagement is low [7], warranting investigation into how these interventions can be designed and implemented to sustain engagement and achieve population-level impact.

Engagement is a key mechanism for behavioral change [8]. Research on engagement with digital interventions has largely been conducted within behavioral science, which typically defines engagement as the extent of program use (eg, amount, frequency, duration, and depth), although its operationalization varies widely across studies [9]. While engagement challenges are not unique to digital delivery, they may be amplified by structural inequalities in digital access and use, particularly in LMICs.

Families living in poverty or rural areas often rely on lower-performing devices, have limited internet connectivity, and face digital literacy challenges [10]. In Tanzania, for example, 82% of the population owns a basic mobile phone, compared with just 35% who own a smartphone [11]. Gender disparities in digital access further compound these barriers. Across LMICs, women are 17% less likely to own a mobile phone and 21% less likely to use the internet than men [12]. These digital divides risk excluding already marginalized families and may deepen health and social inequities if unaddressed. Identifying which caregivers are most likely to engage, or disengage, is therefore essential for developing equitable and effective digital parenting interventions.

Existing evidence on caregiver engagement with digital parenting programs remains limited and inconsistent, with relatively few studies conducted in LMICs [7]. Gender disparities are well documented in in-person programs, where fathers engage at markedly lower rates than mothers [13,14]. In a South African trial of the in-person Parenting for Lifelong Health (PLH) Teens program, fathers represented only 3% of participants and were significantly less likely to attend sessions than mothers [15]. Encouragingly, early evidence from high-income countries (HICs) suggests mothers and fathers engage at similar rates in digitally delivered parenting programs [16,17]. Whether these findings extend to LMICs remains unknown.

Beyond gender, evidence on caregiver-level predictors remains limited. Sociodemographic factors appear to be the most extensively studied in digital parenting interventions, with lower education and income consistently linked to reduced engagement and increased attrition in HICs [17-21]. Similar associations have been reported in in-person parenting programs in HICs [22]. By contrast, findings from a few in-person programs in LMICs suggest that socioeconomic disadvantage does not reliably predict lower engagement [15]. Evidence on behavioral and psychological predictors is comparatively limited and mixed, with positive parenting practices [21,23] and caregiver mental health [16,20,21,24] both associated with higher and lower engagement in digital parenting programs. To our knowledge, no studies of digital parenting interventions have examined these associations in LMICs.

The current study therefore examines caregiver-level predictors of engagement in an early version of ParentApp, a digital parenting intervention developed for caregivers of adolescents in LMICs. Using data from a cluster-randomized factorial trial in Tanzania, implemented in accordance with the optimization phase of the Multiphase Optimization Strategy (MOST) [25], we test whether caregiver demographic, socioeconomic, behavioral, and psychological characteristics predict user engagement. We also explore whether these associations differ by caregiver gender. Findings are intended to inform targeted and inclusive strategies to enhance engagement in ParentApp and, more broadly, support the equitable scale-up of digital parenting interventions in LMICs.

Methods

Study Design

This study was nested within a 2 × 2 × 2 cluster-randomized full factorial experiment implemented across 16 low-income urban and periurban communities in Mwanza, Tanzania [26]. Each community (cluster) was randomly assigned to one of 8 experimental conditions, comprising all possible combinations of 3 components: guidance (guided vs self-guided), app design (structured vs unstructured), and digital support (enhanced vs basic). The trial aimed to optimize user engagement with ParentApp, which was developed in partnership with the United Nations Children's Fund, the World Health Organization, and the Tanzanian national government. The trial was preregistered on the Pan-African Clinical Trial Registry (PACTR202210657553944) on October 11, 2022. Further information about the trial design and findings can be found in the study protocol and related trial publications [26-28].

Participants

Eligible participants were required to be at least 18 years old, be caring for an adolescent aged 10 to 17 years, reside in the same household as the adolescent for at least 4 nights per week during the previous month, and have regular access to an Android smartphone (OS 5.1.1 or higher). To address the

XSL•FO
RenderX

underrepresentation of fathers in parenting interventions, the study aimed to enroll at least 20% men. Participants were recruited on a rolling basis between October 24, 2022 and December 1, 2022, through local community leaders, who were predominantly men. Community leaders introduced and endorsed the study during community meetings, helping to build trust and acceptability among families.

Interventions

ParentApp

ParentApp is designed to promote positive parenting, prevent violence against adolescents, and reduce risks of sexual violence victimization. It is a smartphone-based adaptation of the in-person PLH Teens program, originally developed and evaluated in South Africa [29] and subsequently implemented across multiple LMICs, including Tanzania [30]. ParentApp was developed to expand reach and reduce costs and logistical barriers of in-person delivery. To support use in settings with limited or intermittent internet access, it operates offline after the initial download.

Development and testing followed a multiphase process guided by the MOST framework [25]. During the preparation phase, co-design, multicountry user testing [31], and pilot studies in South Africa and Tanzania demonstrated that the app was broadly acceptable. The preparation phase also identified opportunities to strengthen delivery through additional human support, greater flexibility in accessing content, culturally adapted imagery, and enhanced digital support for caregivers with lower smartphone literacy. These findings informed the selection of the 3 components evaluated in the optimization-phase factorial trial: guidance, app design, and digital support [26].

The intervention content tested in the factorial trial was organized into 12 modules, delivered via simple text, illustrations, and audio narration in Kiswahili. The introductory module focuses on parental self-care and stress reduction and includes a baseline questionnaire. Modules 2 to 11 introduce evidence-based strategies to support positive parenting and reduce harsh or abusive discipline, while also incorporating mindfulness-based exercises throughout. The final module provides a summary of key concepts and includes a postintervention assessment. Full details on module content, home practice activities, and user interface design are available in Janowski et al [26].

Experimental Components

Guidance

The guidance component compared self-guided use of ParentApp with facilitator-supported delivery. Following onboarding, participants in the self-guided condition used the app independently, whereas those in the guided condition used the app alongside a facilitator-moderated WhatsApp (Meta Platforms, Inc) group corresponding to their cluster allocation. Each group was cofacilitated by a mixed-gender facilitator pair to encourage engagement among both women and men. Following a standardized facilitation manual, facilitators posted weekly reminders and discussion prompts, responded to participants' questions, moderated discussions, and hosted weekly 1-hour live chat sessions throughout the 12-week intervention period to support peer interaction and reflection.

App Design

The app design component compared a structured and an unstructured version of ParentApp. In the structured condition, modules were released sequentially over the 12-week intervention and retained the original abstract blue cartoon characters, which were designed without gender-specific characteristics and developed for cross-cultural implementation during earlier pilot studies. In the unstructured condition, all modules were available immediately following installation, allowing participants to progress through the content at their own pace, and featured culturally adapted, human-like illustrations depicting both women and men in caregiving roles.

Digital Support

All participants received basic digital support consisting of an embedded app tutorial and a group-based demonstration of key app features during onboarding. Clusters allocated to the enhanced digital support condition additionally received a 15‐to 20-minute group-based training session designed to improve general smartphone literacy and users' confidence in navigating their devices.

Procedures

Cluster-level onboarding sessions were conducted in local schools and community centers by staff from Tanzania's National Institute for Medical Research (NIMR) and trained facilitators from Investing in Children and Strengthening Their Societies, a local nongovernmental organization. Sessions included study information, eligibility screening, and informed consent, followed by app onboarding and baseline data collection. After obtaining informed consent, participants were divided into small groups (5‐10 caregivers) to facilitate hands-on support with downloading and installing ParentApp from the Google Play Store. Following installation, NIMR research assistants moved between participants to configure each app according to the cluster's allocated intervention condition before guiding caregivers through the app's core features, including navigation, activity completion, and available resources. Participants then completed the introductory module, which included the embedded baseline assessment. Clusters allocated to the enhanced digital support condition also participated in a brief group-based smartphone literacy session, while those allocated to the guided condition were added to facilitator-moderated WhatsApp groups.

Measures

Engagement Metrics

Engagement was assessed using automatically recorded in-app usage data. Usage data, including app launches, content viewing patterns, and responses to in-app tasks, were uploaded to a Metabase cloud server when participants' devices connected to the internet. Retention was calculated as the number of days between the first app launch and the final synchronization of app usage data with the cloud server. Additional usage data, including visit timestamps, session duration, and frequency of

XSL•FO
RenderX

actions or pages viewed, were captured via Matomo Analytics (InnoCraft Ltd). These data were used to derive descriptive indicators and the primary and secondary outcomes.

The primary outcome was module completion, defined as the total number of modules completed (range 0 - 12). Secondary outcomes included the first module not started and the first module not completed, which identified the earliest point in the intervention sequence at which participants either failed to initiate or failed to complete a module, respectively. These outcomes were selected to capture cumulative content engagement and early points of disengagement.

Candidate Predictors

Demographic and Socioeconomic Variables

Baseline data were collected via an in-app questionnaire embedded in the first module. Measures were translated and back-translated into Kiswahili. Candidate demographic predictors included caregiver gender (woman or man) and age (y). Additional demographics (eg, household composition) were collected but not analyzed here. Candidate socioeconomic predictors included financial stress and food insecurity, assessed using 2 items adapted from the Financial Self-Efficacy Scale [32]. Financial stress was assessed by asking, "How many times in the past month have you felt worried or anxious about money?" rated on a 0 to 8 or more frequency scale. Food insecurity was assessed by asking, "How many days in the past month did you run out of money to pay for food?" rated from 0 to 30 days. The 2 items were analyzed separately due to differences in response formats.

Behavioral and Psychological Variables

Positive parenting was assessed using 5 items on parental involvement and supervision from the Alabama Parenting Questionnaire [33]. Items were scored from 0 to 8 or more and summed to produce a total score, with higher scores indicating greater positive parenting. Harsh parenting was assessed using 4 items on physical and emotional abuse from the International Society for Prevention of Child Abuse and Neglect Screening Tools-Trial Version [34]. Items were scored from 0 to 8 or more and summed, with higher scores indicating greater maltreatment. Caregiver depression was measured using 3 items from the Center for Epidemiologic Studies Depression Scale [35]. Each item was scored from 0 to 7 and summed, with higher scores indicating greater depressive symptoms.

Statistical Analysis

Analyses were conducted in R (version 4.5.0; R Foundation for Statistical Computing). Sample characteristics were summarized overall and by caregiver gender. Gender differences in age, financial stress, food insecurity, positive parenting, harsh parenting, and depressive symptoms were assessed using 2-tailed Welch independent-samples *t* tests, with Cohen *d* calculated to estimate effect sizes. Engagement across the 12 modules was visualized using Kaplan-Meier survival curves stratified by caregiver gender.

Predictors of engagement were estimated using Poisson generalized linear mixed models with cluster-level random intercepts. Models were fit to multiply imputed datasets to address missing baseline data, and estimates were pooled across imputations [36]. The primary outcome (number of modules completed) was modeled using an offset for exposure, defined as the number of modules available to each participant. Secondary outcomes (first nonstart and first noncompletion) were modeled as event indicators (1=event, 0=none), with an offset for the number of modules at risk. For participants who experienced an event, the number of modules at risk was defined by the module at which the first disengagement event occurred; for those who did not experience an event, it was defined as the total number of modules available.

Each predictor was tested in a separate model, as the aim was to identify caregiver characteristics associated with engagement that could inform future intervention design and optimization. Predictors were group-mean centered within clusters to isolate within-cluster effects. All models adjusted for the experimental components (dummy-coded for guidance, app design, and digital support). Caregiver age and gender (grand-mean centered) were also included as covariates, except when either variable was the predictor of interest. The potential moderating effect of caregiver gender was examined by including an interaction term between the predictor of interest and gender. Gender was represented both as a group-mean centered variable and as a cluster-level mean to disaggregate individual- and cluster-level effects. Model estimates are reported as incidence rate ratios with 95% CIs and corresponding *P* values. The Benjamini-Hochberg procedure was applied to control the false discovery rate across models, with significance determined using the adjusted critical *P* value thresholds [37].

Ethical Considerations

Ethics approval was granted by the University of Oxford's Departmental Research Ethics Committee (R69744/RE001) and the Tanzanian NIMR (NIMR/HQ/R.8s/Vol.IX/3856). Written informed consent was obtained from all study participants at the onboarding session. To support WhatsApp participation and app-server data synchronization, all participants received 1 GB of mobile data per month for the study duration. Participants received US $2 (US $1=TZS 2319.79 as of October 24, 2022) after completing the onboarding session.

Results

Characteristics of the Sample

Baseline characteristics for the full sample and by caregiver gender are presented in Table 1. The trial included 614 caregivers (409 women and 205 men), with ages ranging from 18 to 75 years (mean age 35.94, SD 11.84). Independent-samples 2-tailed *t* tests indicated no significant gender differences in age or positive parenting practices. However, women reported significantly higher levels of several socioeconomic and psychosocial stressors compared to men, including financial stress (mean 4.55, SD 2.73 vs mean 3.72, SD 2.73; *P*<.001; Cohen *d*=0.30), food insecurity (mean 7.88, SD 8.09 vs mean 6.17, SD 7.01; *P*=.009; Cohen *d*=0.22), harsh parenting (mean 7.40, SD 6.42 vs mean 5.07, SD 6.14; *P*<.001; Cohen *d*=0.37), and depressive symptoms (mean 8.53, SD 4.12 vs mean 7.80, SD 3.56; *P*=.02; Cohen *d*=0.19). Although effect sizes were

XSL•FO
RenderX

small, the findings indicate consistent gender differences in exposure to adversity in the sample.

Table . Caregiver characteristics overall and by gender, with independent-samples 2-tailed *t* test comparisons.

Measure	Overall		Women		Men		Gender comparison[a]	
	n	Mean (SD)	n	Mean (SD)	n	Mean (SD)	Cohen *d*	*P* value
Age (y)	577	35.94 (11.84)	386	35.70 (11.15)	191	36.43 (13.13)	0.06	.51
Financial stress	574	4.27 (2.75)	379	4.55 (2.73)	195	3.72 (2.73)	0.30	.001
Food insecurity	576	7.30 (7.78)	381	7.88 (8.09)	195	6.17 (7.01)	0.22	.009
Positive parenting	614	10.89 (6.78)	409	10.95 (6.84)	205	10.79 (6.69)	0.02	.78
Harsh parenting	614	6.62 (6.42)	409	7.40 (6.42)	205	5.07 (6.14)	0.37	<.001
Parental depression	614	8.29 (3.95)	409	8.53 (4.12)	205	7.80 (3.56)	0.19	.02

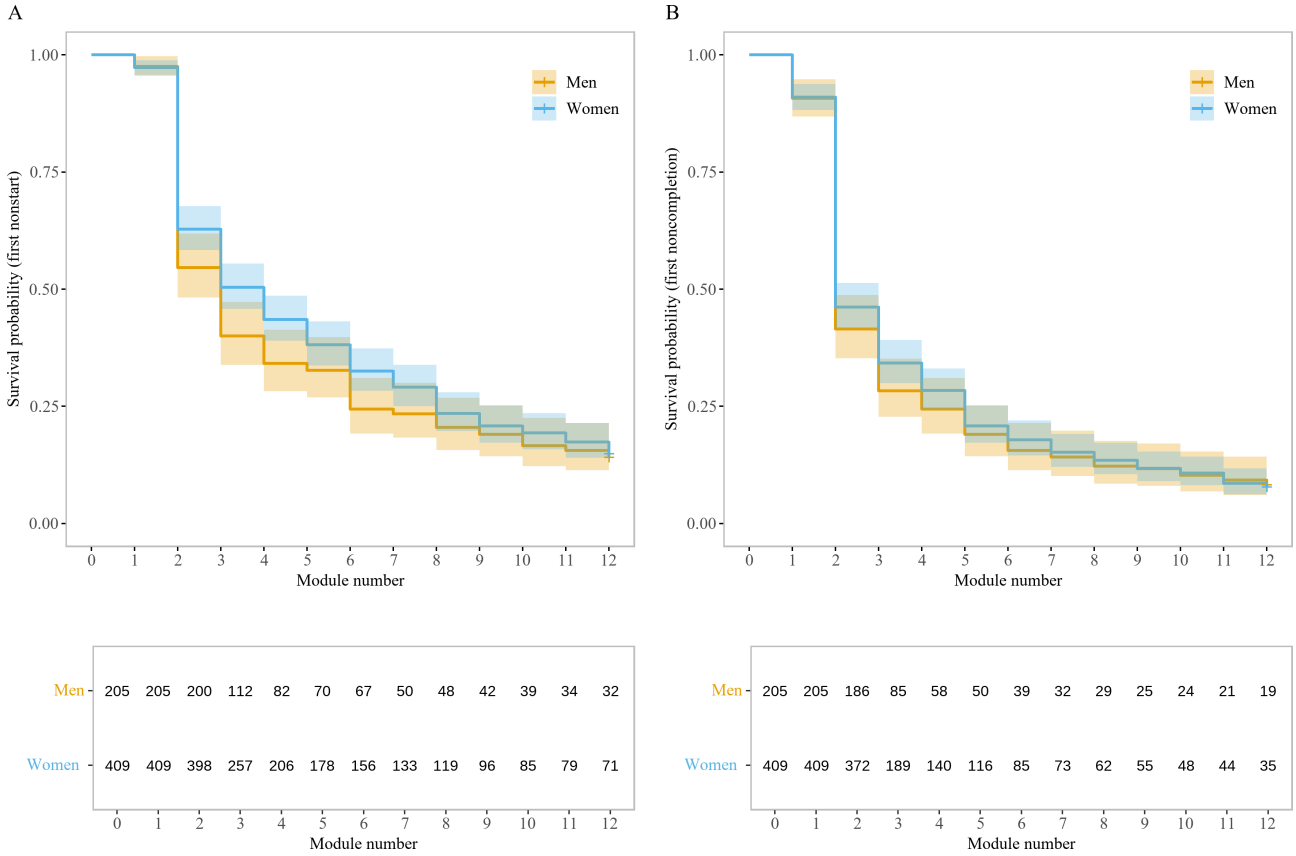
[a]Gender comparisons were assessed using 2-tailed Welch independent-samples *t* tests. Cohen *d* represents the standardized mean difference between women and men, with positive values indicating higher scores for women. Effect sizes are interpreted as small (*d*=0.20), medium (*d*=0.50), and large (*d*=0.80).

Program Engagement

Descriptives

Of the 614 enrolled caregivers, 97.1% (n=596) initiated the first module, and 90.2% (n=554) completed it. This initial uptake was followed by a marked decline in engagement. By module 2, only 59.8% (n=367) had started the module, and 45.8% (n=281) had completed it. On average, participants started 4.57 (SD 4.13) modules and completed 3.40 (SD 3.64) of the 12 available modules (Table 2). The mean content completion rate across all 12 modules was 35.57% (SD 33.10%) of the program. Completion rates were higher among participants assigned to the guided delivery, unstructured design, and enhanced digital support conditions.

Table . Modules started and completed: overall and by experimental component[a].



Variable	Overall	Guidance		App design		Digital support	
		Self-guided (n=330)	Guided (n=284)	Structured (n=332)	Unstructured (n=282)	Basic (n=295)	Enhanced (n=319)
Modules started	4.57 (4.13)	4.22 (3.92)	4.99 (4.33)	4.34 (4.03)	4.84 (4.23)	4.43 (4.04)	4.71 (4.21)
Modules completed	3.40 (3.64)	3.09 (3.41)	3.77 (3.85)	2.91 (3.04)	3.99 (4.16)	3.26 (3.51)	3.54 (3.75)

[a]Values are presented as mean (SD); possible range, 0-12 modules.

Kaplan-Meier survival analyses indicated that the median retention time among content users was 31 days (95% CI 25 - 36), defined as the time between first app launch and final data synchronization with the server. As shown in Figure 1, the risk of disengagement was highest immediately after the first module. Women showed a slightly lower risk of disengagement compared to men for both time to first nonstart and time to first noncompletion, although neither difference was statistically significant.

XSL•FO
RenderX

Figure 1. Kaplan-Meier survival curves for (A) first module nonstart and (B) first module noncompletion, stratified by caregiver gender. Curves show the estimated probability of engaging without a first nonstart or noncompletion, respectively, across the 12-module intervention. Risk tables show the number of participants remaining engaged for each module. Shaded areas indicate 95% CIs.

Predictors of Engagement

Each of the 3 engagement outcomes was regressed on 7 baseline predictors, yielding 21 primary hypothesis tests. To control for the false discovery rate within each outcome, the Benjamini-Hochberg procedure was applied separately to each set of 7 tests [37]. The procedure compares each *P* value to a ranked critical value, and only those below the corresponding threshold were considered statistically significant. Statistically significant effects are highlighted in bold in Table 3.

Caregiver gender was the only baseline characteristic significantly associated with module completion. On average, women completed approximately 15% more modules than men (incidence rate ratio 1.15, 95% CI 1.05 - 1.27, *P*=.003; Table 3). Caregiver gender showed a similar pattern of association with the two secondary outcomes, with women having lower first nonstart and first noncompletion rates than men, although neither association was statistically significant.

XSL•FO
RenderX

Table . Baseline predictors of program engagement[a].

Predictor	Modules completed		First nonstart		First noncomplete	
	IRR[b] (95% CI)	*P* value	IRR (95% CI)	*P* value	IRR (95% CI)	*P* value
Caregiver gender[c]	1.15 (1.05 - 1.27)	.003	0.90 (0.74 - 1.08)	.25	0.92 (0.77 - 1.10)	.37
Caregiver age	1.02 (0.98 - 1.07)	.29	0.96 (0.90 - 1.04)	.33	0.99 (0.92 - 1.07)	.80
Financial stress	1.02 (1.00 - 1.04)	.06	0.98 (0.93 - 1.01)	.16	0.98 (0.95 - 1.01)	.31
Food insecurity	1.00 (1.00 - 1.01)	.67	1.00 (0.99 - 1.02)	.52	1.00 (0.98 - 1.02)	.41
Positive parenting	1.00 (0.99 - 1.02)	.57	1.00 (0.99 - 1.02)	.71	1.00 (0.99 - 1.02)	.71
Harsh parenting	1.00 (0.99 - 1.01)	.87	1.00 (0.98 - 1.01)	.70	1.00 (0.99 - 1.04)	.93
Parental depression	0.99 (0.98 - 1.01)	.22	1.00 (0.98 - 1.03)	.83	1.01 (0.99 - 1.04)	.32

[a]All predictors were group-mean centered within clusters. Caregiver gender was dummy-coded (0=men, 1=women), with estimates representing effects for women relative to men (reference group). All models adjusted for the experimental components (dummy-coded guidance, app design, and digital support). Caregiver age and gender (grand-mean centered) were included as covariates unless either was the predictor of interest.

[b]IRR: incidence rate ratio.

[c]Effect significant below the Benjamini-Hochberg procedure's critical value.

Moderating Effects of Caregiver Gender

To examine whether the associations between baseline characteristics and engagement outcomes differed by caregiver gender, moderation models were estimated for each of the 7 predictors across all 3 outcomes (Table 4). As with the main-effects models, the Benjamini-Hochberg procedure was applied separately within each outcome to control the false discovery rate. For module completion, interactions between gender and food insecurity and between gender and depressive symptoms approached statistical significance; however, neither met the Benjamini-Hochberg threshold. No significant gender interactions were observed for the secondary outcomes.

XSL•FO
RenderX

Table . Moderating effects of gender on associations between baseline predictors and program engagement[a].

Predictor and outcome	Main effect		Interaction effect	
	IRR[b] (95% CI)	*P* value	IRR (95% CI)	*P* value
Caregiver age				
Modules completed	1.02 (0.98 - 1.06)	.41	0.92 (0.84-1.00)	.05
First nonstart	0.97 (0.90 - 1.05)	.49	1.09 (0.92 - 1.28)	.33
First noncomplete	0.99 (0.93 - 1.08)	.95	1.08 (0.92 - 1.27)	.33
Financial stress				
Modules completed	1.02 (1.00 - 1.04)	.06	0.99 (0.96 - 1.03)	.76
First nonstart	0.98 (0.95 - 1.01)	.15	1.01 (0.94 - 1.09)	.76
First noncomplete	0.98 (0.95 - 1.02)	.31	1.00 (0.93 - 1.07)	.93

First nonstart	1.00 (0.98 - 1.01)	.68	0.99 (0.96 - 1.03)	.74
First noncomplete	1.00 (0.99 - 1.01)	.86	0.98 (0.95 - 1.02)	.33
Caregiver depression				
Modules completed	0.99 (0.98 - 1.01)	.38	0.97 (0.94 - 1.00)	.04
First nonstart	1.00 (0.98 - 1.03)	.86	1.03 (0.97 - 1.09)	.38
First noncomplete	1.01 (0.99 - 1.04)	.32	1.02 (0.97 - 1.08)	.45

[a]All predictors were group-mean centered within clusters. Caregiver gender was dummy-coded (0=men, 1=women), with interaction terms estimating differential effects for women relative to men (reference group). Gender was represented as both a group-mean centered variable (within-cluster effect) and a cluster-level mean (between-cluster effect). Caregiver age (grand-mean centered) was included as a covariate in all models except when it was the predictor of interest. All models also adjusted for the 3 dummy-coded experimental components (guidance, app design, and digital support).

[b]IRR: incidence rate ratio.

Discussion

Principal Findings

This study provides the first known analysis of caregiver-level predictors of engagement with a digital parenting program in an LMIC, with the notable strength of including a large proportion of men and fathers (205/614, 33.4%). While nearly all participants initiated the program, engagement dropped substantially after onboarding, with the steepest decline occurring after the first module. This mirrors broader trends in digital health interventions, where attrition is typically concentrated in the early stages of program use [38]. These findings highlight the importance of prioritizing retention strategies early in the intervention.

Of the baseline characteristics examined, caregiver gender was the only statistically significant predictor of engagement. Women completed approximately 15% more modules than men, a finding that contrasts with several digital parenting studies in HICs, where engagement is often similar across genders [17]. One possible explanation is that women's higher engagement may reflect greater exposure to socioeconomic and psychosocial adversity, including financial stress, food insecurity, depressive symptoms, and harsh disciplinary practices. Women reported significantly higher levels of each of these stressors, which may have increased the perceived relevance of the intervention and, in turn, their motivation to engage.

This interpretation aligns with the Health Belief Model [39], which posits that individuals are more likely to adopt health behaviors when they perceive the risks of inaction as high and the benefits of action as tangible. From this perspective,

XSL•FO
RenderX

socioeconomic and psychosocial adversity may have served as a cue to action, outweighing emotional or cognitive barriers that might otherwise prevent engagement [40]. That women sustained engagement despite multiple, overlapping stressors is a notable finding. It suggests that digital parenting interventions may offer a feasible and acceptable modality for supporting high-risk caregivers in LMICs.

In contrast, the lower engagement observed among men may reflect a complex interplay of identity, norms, and structural constraints. In Tanzania and many other LMICs, caregiving is typically viewed as a maternal responsibility, while fatherhood is closely tied to provision, protection, and authority [41-43]. When program content is perceived as incongruent with these gendered expectations or fails to affirm men's aspirations as fathers, it may appear irrelevant or incompatible with their roles. This is echoed in global fatherhood research showing that interventions which acknowledge and support men's caregiving identities and align with their aspirations tend to enhance perceived relevance and achieve higher engagement [13,44].

Lower engagement among men may also reflect deeper identity tensions under conditions of economic precarity. Qualitative research from Mwanza, Tanzania describes how many men aspire to be nurturing and involved fathers but face conflicting practical and social pressures from work demands, limited time, and community norms [43]. These experiences not only restrict men's capacity to participate in caregiving but may also lead to internal dissonance when they are unable to fulfill culturally sanctioned roles of fatherhood, a phenomenon that has been described as *moral injury* in fatherhood research [45,46]. Similar findings from Uganda indicate that even when men express egalitarian views, structural constraints and social stigma around caregiving can limit their involvement in parenting programs [47]. These dynamics highlight the need for interventions that actively affirm men's caregiving identities and address the structural barriers that limit engagement. While women reported greater socioeconomic adversity in the present study, integrating digital parenting programs with broader economic and social protection initiatives may help reduce the opportunity costs of participation for both men and women [48].

Although ParentApp was intentionally designed to support all caregivers rather than assuming mothers as the primary users, these findings suggest that additional strategies may be needed to improve engagement among men. Future iterations could benefit from further co-design with fathers to better understand how intervention content, tone, imagery, and delivery align with men's caregiving identities and everyday constraints. Emerging work on digital fatherhood interventions illustrates how user-centered design can be used to develop app-based support tailored to fathers' mental health, well-being, and parenting needs [49]. However, improving engagement among men may require more than tailoring content or delivery; it may also require gender-transformative approaches that actively challenge inequitable norms and support identity shifts in caregiving. As highlighted in a recent systematic review of fatherhood programs in LMICs, gender-transformative interventions foster critical reflection, promote shared decision-making, and engage with normative change at individual and community levels [48]. Promising examples include in-person parenting programs such as REAL Fathers in Uganda [50], Bandebereho in Rwanda [51], and Parenting for Respectability in Uganda [52], which have achieved shifts in father involvement, reductions in intimate partner violence (IPV), and improvements in household dynamics through facilitated dialogue, peer role-modeling, and local leadership.

Emerging evidence suggests that gender-transformative components can be successfully integrated into digital formats. One example is ParentText, a chatbot-based parenting intervention adapted from the PLH program suite and piloted in South Africa and Jamaica. ParentText incorporates content on gender-equitable behaviors and IPV prevention to support shared caregiving, challenge harmful gender norms, and reduce familial violence [53]. Qualitative findings suggest that men valued the anonymity, accessibility, and nonjudgmental tone of the chatbot, which facilitated engagement with sensitive topics such as relationships and caregiving [54]. A parallel pre-post pilot study reported modest reductions in women's experience of IPV and improvements in men's attitudes and gender-equitable behaviors. However, overall engagement with the program and with the IPV-related content in particular was limited, especially among men [55]. Together with the findings of the present study, this emerging evidence suggests that moving beyond one-size-fits-all approaches may be key to improving engagement with digital parenting interventions.

Limitations

Several limitations should be acknowledged when interpreting these findings. First, engagement was operationalized using digital metrics (eg, module completion), which offer behavioral indicators of app use but do not capture content comprehension or real-world application. This reflects a broader challenge in digital health research, where engagement is often equated with usage alone, without consideration of learning or behavior change outcomes [56]. Moreover, these metrics do not capture users' subjective experiences, such as interest, attention, or emotional resonance, which may be equally important in understanding meaningful engagement [9]. Future research should therefore incorporate multidimensional measures that capture both the quantity and quality of engagement, alongside users' subjective experiences.

Second, the range of caregiver characteristics assessed at baseline was limited by the brief, app-embedded format of the survey. Key variables such as perceived digital skills and prior experience with technology were not captured, although these factors have been shown to influence engagement with digital interventions [57,58]. The study also did not measure adolescent-level characteristics, such as child mental health symptoms, which have been positively associated with parental engagement in previous research [56]. Accounting for these variables in future studies may improve the precision of engagement models and support more targeted intervention strategies.

Third, while the overall sample size was relatively large, the study may have been underpowered to detect gender interaction effects, especially given the smaller proportion of men in the sample. Future studies should consider adequately powered subgroup analyses to explore gender-specific patterns of

XSL•FO
RenderX

engagement. Furthermore, although the sample was drawn from low-income urban and periurban settings, all participants were required to have regular access to a smartphone. As such, findings may not be generalizable to caregivers in rural areas or those with limited access to digital technology. Broader implementation research is needed to understand how structural barriers such as digital access, network reliability, and device sharing influence engagement, including in rural and more resource-constrained settings.

Conclusions

This study provides important evidence on caregiver engagement with a digital parenting program in an LMIC. Across demographic, socioeconomic, behavioral, and psychological factors, only caregiver gender significantly predicted engagement, with women completing more modules than men. The absence of significant associations with other baseline characteristics provides encouraging evidence that socioeconomic and psychosocial factors may not pose substantial barriers to engagement with ParentApp. However, high rates of attrition among both men and women immediately after onboarding highlight early disengagement as a critical challenge. Addressing this challenge will be essential if digital parenting programs are to achieve meaningful and lasting benefits for children and families in LMICs.

Acknowledgments

We would like to thank our partners at the Tanzanian National Institute for Medical Research (NIMR) and Investing in Children and Strengthening Their Societies (ICS) for their leadership, guidance, and implementation support, including community mapping, recruitment, app onboarding, and the delivery of WhatsApp groups. We would also like to thank our partners at Innovations in Development, Education, and the Mathematical Sciences (IDEMS International and INNODEMS Kenya), and Clowns Without Borders South Africa for their technical leadership in intervention development, content adaptation, data collection, facilitator training, and implementation support. Above all, we are grateful to the participating families whose input made this research possible.

During manuscript preparation, the authors used ChatGPT (OpenAI) to assist with language editing and to improve the clarity and readability of the manuscript. All scientific content, interpretations, and conclusions were developed and verified by the authors, who take full responsibility for the final manuscript.

Funding

This study was funded by the UK Research and Innovation Global Challenges Research Fund Accelerating Achievement for Africa's Adolescents (Accelerate) Hub (ES/S008101/1), the Wellspring Philanthropic Foundation (16204), the European Research Council under the Proof of Concept 2022 Call (101067451), and a private family trust that wishes to remain anonymous. This study is also part of the Global Parenting Initiative, which is funded by the LEGO Foundation and the Oak Foundation. RJ was supported by the UK Research and Innovation Economic and Social Research Council Grand Union Doctoral Training Partnership. YS was supported by the Centre for Development, Evaluation, Complexity, and Implementation in Public Health (DECIPHer) and the Wolfson Centre for Young People's Mental Health. DECIPHer is funded by the Welsh government through Health and Care Research Wales. The Wolfson Centre for Young People's Mental Health has been established with support from the Wolfson Foundation.

Data Availability

The datasets generated or analyzed during this study are not currently publicly available due to ongoing analyses but will be made available via the Open Science Framework upon study completion. In the interim, datasets are available from the corresponding author on reasonable request.

Authors' Contributions

RJ led the conceptualization, data analysis, and writing of the original, revised, and final manuscript drafts. LDC, YS, GJM-T, and LJvN contributed to the critical revision of the manuscript. GJM-T provided key input on the statistical analysis. All authors read and approved the final version of this manuscript.

Conflicts of Interest

RJ's doctoral research is based on this trial. JML is the chief executive officer, and LDC is a voluntary trustee of Parenting for Lifelong Health (PLH), a charity based in the United Kingdom and South Africa. JML receives occasional fees for providing training and supervision for PLH programs. Members of the research team have worked on other studies of PLH, which contributed funding to their respective universities but not directly to them. The intellectual property for the intervention is owned by the developers of the original intervention under a Creative Commons Attribution-NonCommercial-NoDerivatives 4.0 International Public License. No profit or financial gain will be made from the implementation and dissemination of the intervention.

Abstract

Background: Despite evidence showing that parenting interventions reduce rates of child mental health problems, their reach and engagement remain low. Daily Growth is a digital parenting program designed to improve parent and child emotion regulation using an ecological momentary intervention (EMI) approach. Daily Growth sends twice-daily prompts and delivers 3-minute videos tailored to a recent parenting situation, offering 2 program types (Emotion Coaching and Active Play) to meet different parent preferences. EMI has rarely been tested with parenting programs.

Objective: This pilot aimed to assess the feasibility and acceptability of the EMI design and a prototype of Daily Growth, offering the 2 programs via 10 of 60 planned videos.

Methods: A pilot randomized controlled trial recruited 189 Australian parents of children aged 2‐4 years, randomized to either intervention (n=94) or active control (n=95). Participants completed a 25-minute online survey at baseline and at conclusion of the program period. In the intervening 2 weeks, participants received twice-daily 1-minute pre-EMI surveys via email. Participants who reported any parent or child negative affect or emotion dysregulation received a resource. Participants in the intervention condition were randomized in the moment to receive a 3-minute Emotion Coaching or Active Play video, while participants in the control condition received a link to a parenting website. Participants were sent a 1-minute post-EMI survey. For both conditions, parenting support was tailored to 1 of 5 predefined parenting situations.

Results: Overall, 71% (135/189) of participants completed the 2-week post survey, and over two-thirds completed at least half of the daily pre-EMI surveys. Despite technical issues, most participants would recommend Daily Growth to other parents (53/67, 79%), use the skills learned (46/67, 69%), reported it as easy to use (45/67, 67%), and were satisfied with Daily Growth (40/67, 60%).

Conclusions: This pilot evaluated whether brief EMI resources could engage parents in real time. Findings suggest that the Daily Growth prototype was feasible and well received, supporting further implementation in a larger trial.

Daily Growth; emotion coaching; Active Play; emotion socialization; intervention; parenting; emotion regulation; child development; ecological momentary intervention

Introduction

Background

Emotion regulation skills influence all aspects of human functioning and are central in the etiology of mental health disorders [1,2]. Parents play a vital role in the development of their child’s emotion regulation skills [3,4], and both parenting beliefs and practices are modifiable. While parenting interventions demonstrate strong effectiveness in improving child emotion regulation and reducing child mental health problems [5,6], their population reach has been extremely low

RenderX

(<10% population) [7,8]. This limited reach disproportionately affects fathers, single parents, and Aboriginal and Torres Strait Islander, migrant, culturally and linguistically diverse, and rural or remote families [8-11]. In response, several parenting interventions have transitioned to online delivery formats to increase access. More recently, smartphone-based parenting apps have further expanded access [12-17]. Online and app-based programs have the potential to make support more accessible, cost-efficient, and anonymous, and have been welcomed by users [13-16,18-20]. However, despite demonstrated efficacy, digital parenting interventions continue to face hurdles such as low uptake, engagement, and adherence [21-24], suggesting that online delivery alone does not fully address barriers to uptake and engagement. At the same time, many parenting programs focus on child behavior change rather than emotion regulation [25-27] and are targeted toward school-aged children or adolescents, despite early childhood representing a critical time for children's emotional development [28]. Together, these limitations point to a need for parenting programs that address both how support is delivered (moving beyond access to sustained engagement) and what is delivered, with a focus on emotion regulation in early childhood.

This Study: Daily Growth

This study is part of a larger research project developing and testing Daily Growth, a personalized, stand-alone parenting app for parents of children aged 2 - 4 years. Daily Growth aims to enhance parent emotion regulation and emotion-related parenting skills, ultimately supporting children's emotion regulation and reducing rates of child mental illness. To address barriers to reach, access, and engagement in population-level parenting programs, the platform integrates novel technological approaches successfully applied in adult health settings [29-32]. In collaboration with parents, carers, and community practitioners, we co-designed Daily Growth using the Design Mapping framework to deliver tailored, in-the-moment parenting support using an ecological momentary intervention (EMI) design. The program offers microinterventions (brief 3-minute video resources) matched to specific parenting situations and combines 2 evidence-based parenting approaches: Emotion Coaching and Active Play.

EMIs deliver brief, frequent support via smartphone apps, aiming to seamlessly integrate into daily life [33,34]. In adult mental health settings, EMI approaches have demonstrated improvements in adherence and reductions in mental health symptoms (eg, gambling, stress, anxiety, and body satisfaction), while requiring less time and fewer resources than traditional interventions [31,32,35,36]. Despite this promise, EMI designs have rarely been tested within parenting interventions [13,37,38]. Of the existing studies, one targeted homeless adolescent mothers (n=49) and demonstrated high acceptability and sustained engagement, with participants reporting that the technology supported parent emotion regulation during stressful parenting moments [13]. A second study was a small feasibility study (n=33) exploring daily reflective questions delivered via ecological momentary assessment (EMA) to increase parental awareness of child emotions and support in-the-moment emotion coaching, suggesting that parents can sustain engagement with daily prompts, and that doing so can increase their attention to child emotions in everyday life [37]. A third study has proposed, but not yet tested, an EMI-based mindfulness intervention for parents of children with autism spectrum disorder (n=670) [38]. No studies to date have examined EMI-based parenting programs that are population-based, target the early childhood period, or specifically aim to build children's emotion regulation skills, and it remains unclear whether this approach will be feasible, engaging, and relevant for parents navigating busy daily routines. A further limitation of previous parenting interventions has been their one-size-fits-all approach, which does not align with evidence that parents vary in the situations and approaches that may be most relevant [20,39-41] and beneficial to them [42]. Tailoring brief microinterventions to parents' needs may increase the relevance of parenting support and encourage sustained engagement over time. Additionally, collaborating with end users in mental health research has been shown to improve program relevance, engagement, and effectiveness [43]. Integrating tailoring with a co-design approach may therefore strengthen both the relevance and usability of digital parenting support.

Daily Growth was developed according to these principles, delivering brief, tailored resources informed by input from parent end users and professionals. It provides in-the-moment support through 2 distinct programs, recognizing that parents support child emotion regulation through multiple pathways. Emotion Coaching is based on Gottman et al.'s 5 steps [44,45]: noticing emotions, viewing them as teaching opportunities, responding with empathy, labeling emotions, and problem solving. Daily Growth adds a sixth step (reflect), encouraging parents to pause when calm, consider their responses, and model repair. Active Play offers a nonverbal, embodied approach suited to parents less comfortable with emotional talk. Drawing on evidence that physical activity and imaginative play support mood regulation, calm the nervous system, and strengthen executive function tied to emotion regulation [46-48], the program provides practical play-based activities to support parent-child connection and emotion regulation.

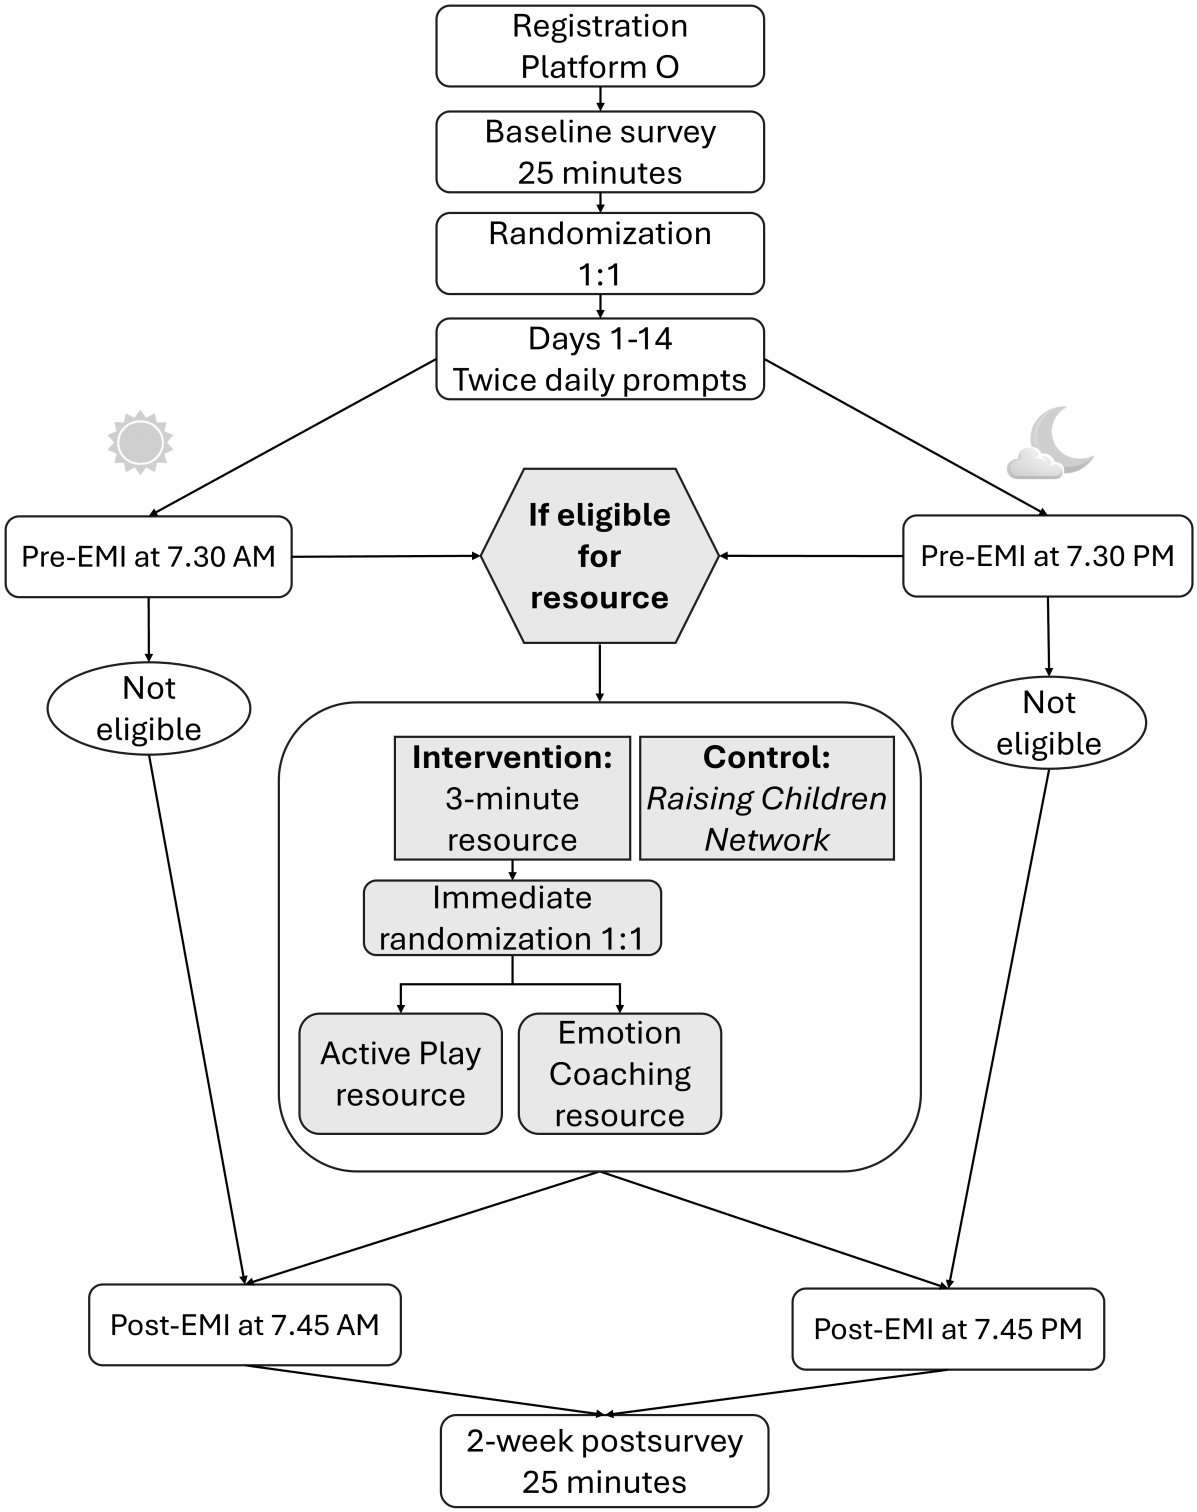
This pilot study evaluates the feasibility and acceptability of the prototype version of Daily Growth and its EMI delivery approach, delivered over 2 weeks, compared with an active control condition. Specifically, we aimed to assess:

1. The feasibility of the prototype version of Daily Growth in terms of parent recruitment rates, retention, and flow through all stages of the study, as well as parent engagement via completion rates of the baseline survey, 2-week post survey, and daily prompts.
2. The acceptability of the 10 prototype video resources and the program delivery method via twice-daily pre- and post-EMI prompts.
3. The descriptive efficacy of the prototype version of the Daily Growth program in improving parent and child emotion regulation, mental health, and emotion coaching parenting behaviors in the moment and postintervention compared with the control condition.

We anticipate that predefined feasibility benchmarks will be met, including meeting the target of recruiting at least 150 participants, attrition below 30%, and average completion of at

XSL•FO
RenderX

least 50% of pre- and post-EMI prompts. This engagement rate is informed by rates reported in parenting EMI and EMA studies, in which 70% of parents engaged with at least 80% of daily EMA prompts in a general parenting population [37] and approximately 40% of prompts were completed among a vulnerable population of homeless adolescent mothers [13]. Acceptability is considered high if 70% of intervention participants indicate that they are satisfied with the program, informed by satisfaction rates reported in parenting EMA or EMI studies [13,37]. As this is a pilot trial, the primary focus is on feasibility and acceptability rather than efficacy testing. Descriptive outcome data are reported to assess the feasibility of the outcome measurement protocol, including the sensitivity of measures to detect change and the completeness of data collection, in preparation for the definitive trial [49,50].



Methods

Research Design

The study design is demonstrated in Figure 1. This study used a pilot randomized controlled trial design with a 1:1 allocation ratio to evaluate the feasibility, acceptability, and descriptive efficacy of a prototype version of the Daily Growth parenting program. The trial was conducted fully online. Participants completed baseline measures via Qualtrics (Qualtrics LLC), followed by a 2-week EMI period during which they received twice-daily pre- and-post-EMI prompts delivered via email. Participants completed a 2-week postprogram survey at the conclusion of the EMI period.

Ethical Considerations

Study procedures were approved by the Deakin University Human Ethics Advisory Group (HEAG-H 188_2022). Participants provided informed consent online via a checkbox before participation to indicate their consent to participate and be contacted about future research. Participants received a Plain Language Statement outlining the study procedures and purpose, estimated duration of each study component, their right to withdraw at any time, the policy regarding data storage, and contact details for the principal investigator for questions or concerns.

XSL•FO
RenderX

Participants and Recruitment

Eligibility criteria included residing in Australia, aged 18 years and older, parent or carer of a child aged 2 - 4 years, English proficiency, internet access, and basic digital literacy (able to receive emails and complete online surveys). Recruitment methods included contacting parents from a registry of participants from related studies who had previously consented to be contacted for future research, posting in Facebook parenting groups, and running paid Facebook and Instagram advertisements. Parents were reimbursed with Coles gift vouchers based on EMI survey completion rates (50% - 69%=AU$20 (AU$1=US $0.67 as of March 18, 2023); 70% - 84%=AU$30; and 85% - 100%=AU$50). No formal power calculation was conducted as the pilot aimed to test feasibility rather than efficacy. A target of 150 participants was set to ensure sufficient data for feasibility assessment. The final sample comprised 189 parents and caregivers (94 intervention, 95 control).

Procedure

Participants registered on the online platform "Platform O" and completed a baseline survey via Qualtrics (Qualtrics LLC), an online survey platform. The baseline survey comprised 224 items, taking approximately 25 minutes to complete. The purpose of the questionnaire was to collect demographic information and to assess parent and child emotion regulation, mental health, and emotion coaching parenting practices. No completeness checks were included; however, participants who did not complete the demographics section were removed from the dataset. An attention check was included, and respondents could not review or change their answers. The research team regularly monitored survey responses for suspicious submissions (eg, duplicate entries, bot responses, and participants located outside of Australia) and excluded illegitimate participants. Following completion of the baseline survey, participants were randomly assigned to either the control or intervention condition on a 1:1 basis using Qualtrics' "Randomiser" feature on completion of the baseline survey. Participants were blinded to their allocation but research team members were not. Participants received their first EMI survey, assessing momentary parent and child affect and emotion regulation, the day after completing the baseline survey. Over the subsequent 14 days, participants received twice-daily email prompts to complete a 1-minute pre-EMI survey at 7:30 AM and 7:30 PM, followed by a 1-minute post-EMI survey prompt at 7:45 AM or 7:45 PM. At the end of the 2-week program period, participants were invited to complete a 2-week post survey via Qualtrics.

Daily Growth Program and Control Condition

Daily Growth was developed using an iterative co-design process involving parents and professionals. Guided by a novel Design Mapping framework [51], development was informed by (1) an analysis of online parenting discussions to identify common parenting challenges [52], (2) qualitative interviews with parents to understand current use of active play as a parenting strategy [53], (3) structured workshops conducted to co-design program content and delivery [54], (4) ongoing consultation with an advisory group consisting of parents and professionals, and (5) a technical EMA pilot to optimize the timing of prompts [55]. The present pilot evaluated a subset of the full Daily Growth program to assess the feasibility, acceptability, and descriptive efficacy of the program prior to development of the final 6-week smartphone app.

Participants allocated to the intervention condition received access to a prototype version of Daily Growth delivered via the online platform Platform O. Daily Growth is a parenting program designed for parents of children aged 2 - 4 years, delivering brief microinterventions using an EMI approach. The prototype included 10 brief 3-minute video resources (5 Emotion Coaching and 5 Active Play) tailored to 5 different parenting situations (mealtime, bedtime, getting dressed, screen time, and sibling conflict). Across the 14-day intervention period, all participants received twice-daily prompts linking to a 1-minute pre-EMI survey. Participants who reported parent or child negative emotion or emotion dysregulation were eligible to receive a tailored parenting resource. Eligible participants selected 1 of 5 difficult parenting situations they had recently experienced or were interested in learning about. Participants in the intervention group were then randomized in the moment to receive either an Emotion Coaching or Active Play video resource tailored to their selected situation. Following resource delivery, participants were prompted to complete a post-EMI survey assessing momentary parent and child affect and emotion regulation. Participants allocated to the active control condition were instead provided with a link to the Raising Children Network, an Australian government–supported parenting information website. The Raising Children Network provides high-quality, but general, parenting information and does not include brief tailored intervention strategies comparable with those delivered by the Daily Growth video resources. The full Daily Growth program currently in development will include 60 video resources delivered over 6 weeks via a custom-built smartphone app for iOS and Android, with twice-daily pre-EMI survey prompts delivered via app notifications [56].

Outcomes

Feasibility

Feasibility was assessed through recruitment, retention, and engagement measures. Recruitment was evaluated based on the ability to achieve the target sample size within the recruitment period. Enrolled participants were defined as those who completed at least the demographic portion of the baseline survey. We aimed for equal representation across child age groups and ≥25% fathers. Retention was measured by attrition rates between baseline and 2-week post surveys. We aimed for <30% attrition in the intervention condition, a benchmark informed by previous intervention studies [11,20,57-61]. Engagement was measured based on the proportion of completed prompts per participant and parent-reported barriers to participation. While EMA studies in adult mental health report close to an 80% average engagement [30,62], Daily Growth reflects the unique context of parenthood, providing flexible, light-touch support without being onerous or interrupting in-the-moment parenting. We therefore prioritized sustained participation over high response rates, targeting 50% pre-EMI completion (1 daily survey on average, providing support 2 - 5

XSL•FO
RenderX

times weekly) and 50% post-EMI completion. Engagement and attrition were analyzed by socioeconomic status, gender, and migrant status, as these demographic variables have been associated with differential access to and engagement with parenting programs [9].

Acceptability

A 25-item user satisfaction measure combined 5-point scales (eg, “The Daily Growth program meets my needs”), multiple-choice questions (eg, “Which parenting resource did you prefer?”), and open-ended questions (eg, “What problems did you encounter while using the program?"). Items assessed content quality, resource design, research experience, perceived effectiveness, and overall program acceptability. The measure was administered at the end of the 2-week program as part of the 2-week post survey. Acceptability was considered high if the majority (>50%) of intervention participants found the program resources and design satisfactory.

Baseline and 2-Week Posturvey Outcome Measures

Study measures are presented in Table 1. The research team selected measures routinely used in large-scale population studies with evidence of good validity and reliability for assessing parent and child emotional and social functioning. The baseline and 2-week post survey collected demographic information and assessed parent and child emotion regulation, mental health, and emotion coaching parenting practices.

EMI Survey Measures

Measures Overview

Momentary parent and child emotion dysregulation and negative affect were reported via twice-daily 1-minute pre- and post-EMI surveys at 7:30 AM and 7:30 PM. These prompts did not expire, and parents could respond at their convenience. The twice-daily EMI surveys were identical to each other except for 1 pre-EMI item asking about difficult parenting situations in the previous 24 hours. Item selection and the schedule for delivering survey prompts were informed by a previous EMA study identifying the most suitable state-based items for capturing in-the-moment parent and child emotion dysregulation and negative affect and times at which parents were most likely to respond to prompts [55]. If a participant scored at or above the predetermined cutoff value on any item of the pre-EMI survey, they were eligible to receive a resource. Eligibility thresholds were defined across 4 domains: parent negative affect (≥1), child negative affect (≥1 for anger and ≥2 for sadness), parent emotion dysregulation (≥1), and child emotion dysregulation (≥2). These thresholds were selected to indicate at least mild elevations in negative affect or emotion dysregulation, warranting in-the-moment support.

Parent and Child Affect

Parent and child negative affect were measured using 3 items drawn from the short-form International Positive and Negative Affect Schedule (I-PANAS-SF) [70] to capture momentary emotional states ("upset," "angry," and "sad"). Items included "Indicate to what extent your child feels this way right now" and "Indicate to what extent you feel this way right now." Parents rated items on a 10-point scale from 1 (not at all) to 10 (extremely), reflecting how they or their child felt "right now, in this moment." These state-based items were selected to align with the trait-based I-PANAS-SF included in the baseline and 2-week post surveys, enabling comparison between momentary and general affect. The resource eligibility thresholds for parent and child negative affect were ≥1 for parent negative affect, ≥1 for child anger, and ≥2 for child sadness.

Parent and Child Emotion Regulation

Parent and child emotion dysregulation were assessed using 3 items from the state-based version of the Difficulties in Emotion Regulation Scale (S-DERS) [78]. Items included "My emotions feel overwhelming" and "I am having difficulty controlling my behaviours." As the original S-DERS was developed for adults, 1 item was adapted to assess child emotion regulation ("My child is having difficulty controlling their behaviours."). Parents rated items on a 10-point scale from 1 (not at all) to 10 (extremely), reflecting their or their child's current emotional state. The resource eligibility thresholds for parent and child emotion regulation were ≥1 for parent emotion dysregulation and ≥2 for child emotion dysregulation.

Statistical Analysis

To evaluate feasibility in terms of participant recruitment, retention, and engagement (aim 1), data from the baseline, 2-week post, and EMI surveys were analyzed using descriptive statistics. Pearson pairwise correlations examined associations between demographic characteristics and engagement with pre- and post-EMI surveys and the 2-week post survey. To evaluate

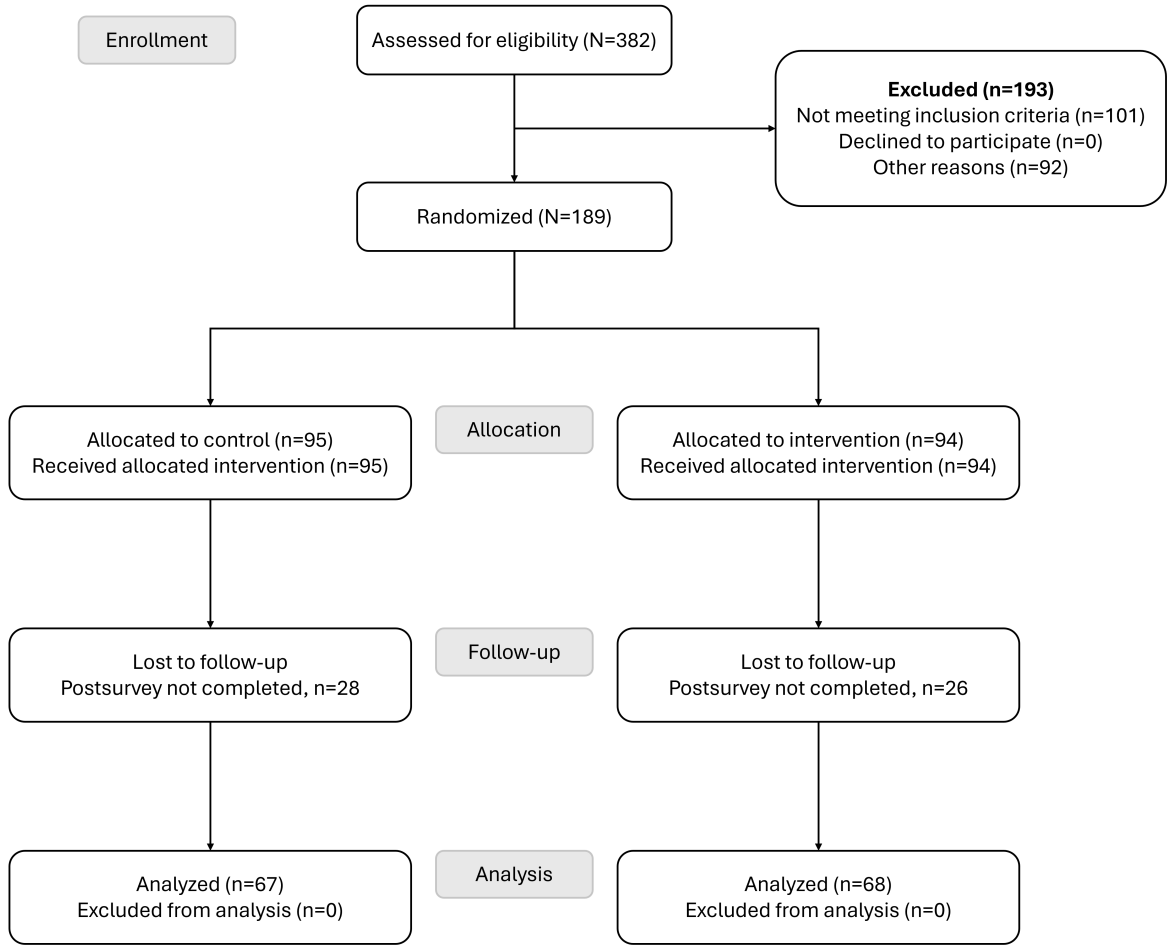
XSL•FO
RenderX

acceptability of the program content and delivery method (aim 2), acceptability items from the 2-week post survey were analyzed descriptively to assess participant feedback about the Daily Growth program. To assess feasibility of the research methods in evaluating the efficacy of Daily Growth (aim 3), 2 sets of analyses were conducted in line with the two survey streams: (1) baseline to 2-week post survey outcomes: Bonferroni-adjusted linear regression analyses were conducted for parent and child outcomes. Each model used a postintervention outcome (eg, parent or child emotion regulation and mental health) as the dependent variable and study condition (intervention or control) as the independent variable. Two models were estimated for each outcome: an unadjusted model examining the association between assigned condition and the 2-week post survey outcome, and an adjusted model controlling for the baseline value of the outcome. Effect sizes were also calculated, with Cohen *d* reported for the unadjusted model and η^2 reported for the adjusted model. (2) EMI outcomes: Post-EMI survey data were analyzed using linear mixed-effects regression models, with condition as the fixed effect and participant as the random effect. Two models were estimated for each outcome: an unadjusted model examining the association between assigned condition and post-EMI outcome, and an adjusted model controlling for the pre-EMI value of the outcome. All analyses were intention-to-treat and used the maximum available data, resulting in variation in sample size per test.

Protocol Deviations and Technical Issues

Several technical issues occurred during the pilot. First, approximately half of the participants did not receive post-EMI surveys due to a programming error that sent surveys only if participants completed their pre-EMI survey within 15 minutes of the invitation email. This was corrected midway through the trial by removing the time restriction and sending post-EMI surveys to all participants regardless of resource eligibility. For analysis, participants were categorized into group 1 (affected by the issue) and group 2 (unaffected by the issue), with both groups balanced across control and intervention conditions and showing no other differences. Second, a programming oversight allowed participants to complete EMI surveys multiple times; only first completions were retained for analysis. Third, EMI survey prompts did not account for participants' time zones, resulting in prompts sent outside intended times for participants residing outside Victoria, New South Wales, Tasmania, or the Australian Capital Territory. Finally, 57 EMI survey responses and 2522 Platform O prompts missing participant IDs were excluded from analysis.

Results



Feasibility Outcomes

Participant Flow

Participant flow is presented in Figure 2. Of the 382 participants assessed for eligibility, approximately half were excluded for reasons including not meeting inclusion criteria, incomplete demographic data, residing outside Australia, being identified as bots, having no EMI prompts assigned, lacking a participant ID, or being duplicate entries. Overall, 71% (135/189) of the participants who completed the baseline survey also completed the 2-week post survey, meeting the prespecified target of <30% attrition.

XSL•FO
RenderX

Figure 2. Participant flow through enrollment, screening, baseline completion, 2-week post survey completion, and analysis.

Participant Demographics

Participant demographics are presented in Table 2. The study enrolled 189 parents and carers of children aged 2 - 4 years, exceeding the recruitment target of 150 participants. Randomization resulted in groups that were broadly comparable on baseline demographic characteristics. The mean participant age was 36.4 (SD 5.2) years in the control group and 36.7 (SD 4.8) years in the intervention group; the overall sample mean age was 36.6 (SD 5.0) years. Most participants were mothers, and the predetermined recruitment target of 25% fathers was not met. Compared with the most recent census of Australian families [23,79,80], single parents and parents of Aboriginal and Torres Strait Islander descent were overrepresented in the study sample. Parents with a low income, born overseas, who speak another language, and those without a university degree were underrepresented.

[b]Not available.

EMI Completion

EMI completion rates over the 2-week study period are presented in Figure 3. On average, participants completed close to two-thirds of the pre-EMI surveys, exceeding the prespecified engagement target of 50%. However, post-EMI survey completion was lower and fell below the prespecified 50% target. Completion rates did not differ substantially between conditions. For pre-EMI surveys, the majority of the participants (57.7%) completed at least 75% of surveys. Around 1 in 6 (17.5%) participants completed fewer than 25% of pre-EMI surveys. In contrast, post-EMI survey completion was low, with most participants (58.2%) completing fewer than 25% of surveys, and only about 1 in 10 (9%) completing at least 75%. Twenty-three participants in group 1 (ie, affected by technical issues) did not receive any post-EMI survey prompts. Figure 4 presents the average pre-EMI survey completion rates across study time points. Completion rates fluctuated between 60% and 80% across the 2-week period.

RenderX

Demographic Characteristics and Engagement

Prespecified Pearson pairwise correlations were conducted to examine associations between pre-EMI survey completion rates and participant demographic characteristics. There was evidence for a small association between participants' pre-EMI survey completion rate and child's age (r=0.15; P=.046), suggesting that completion rates were slightly higher among parents of older children. However, we found no evidence to suggest associations between any other demographic characteristics and pre-EMI completion rates.

Resource Eligibility

Figure 5 presents the number of survey responses per participant that were eligible to receive a resource (ie, scored above the cutoff on the pre-EMI survey). Among all completed pre-EMI surveys, 56% met criteria for receiving a resource, with an average of 43% eligible pre-EMI surveys per participant. On average, parenting support was offered once per day based on the pre-EMI survey cutoff.

Figure 5. Frequency distribution of resource eligibility per participant by day of participation over 2 weeks.

Acceptability

Program acceptability results are shown in Table 3. Interpretation of acceptability outcomes was limited by an error in the survey response options, as both ends of the scale were labeled "Strongly disagree," (ie, participants were shown as Strongly disagree, Disagree, Neutral, Agree, and Strongly disagree), meaning that it was not possible to determine whether participants intended to select the lowest or highest level of acceptability. It is also likely that responses are skewed, as participants who would have selected "Strongly agree" may instead have selected "Agree," given that the "Strongly agree" option was not available. Notably, only a small number of participants selected either "Strongly disagree" response option. For example, for the item "Overall, I am satisfied with the Daily Growth program." only 3% (2/67) selected "Strongly disagree."

As shown in Table 3, the majority of intervention participants who completed the acceptability survey found the Emotion Coaching and Active Play resources useful, with over two-thirds agreeing that the program was easy to use. Just less than half of the participants felt that Daily Growth met their needs, and more than half reported overall satisfaction. Almost half of the participants indicated that the program helped them manage challenging parenting situations, while more than half reported that it improved their understanding of their child's emotions. For nearly half of the participants, the program also strengthened their bond with their child. Additionally, two-thirds planned to continue using the skills they learned. Most participants (94%) reported that the Daily Growth resources were about the right length, and the majority (79%) indicated that they would recommend the program to other parents. However, consistent with the technical issues described earlier, approximately one-third of the participants (31%) reported encountering issues while using the app, most commonly relating to not receiving some EMI surveys.

Table . Acceptability of Daily Growth at 2-week post survey (N=67).

Item	Strongly disagree[a], n (%)	Disagree, n (%)	Neutral, n (%)	Agree, n (%)	Strongly disagree[a], n (%)
I am satisfied with Daily Growth	0 (0)	10 (14.9)	15 (22.4)	40 (59.7)	2 (3)
Daily Growth meets my needs	1 (1.5)	13 (19.4)	21 (31.3)	30 (44.8)	2 (3)
I found Emotion Coaching useful	0 (0)	1 (1.5)	20 (29.9)	43 (64.2)	3 (4.5)
I found Active Play useful	0 (0)	1 (1.5)	27 (40.3)	36 (53.7)	3 (4.5)
Daily Growth was easy to use	0 (0)	7 (10.5)	10 (14.9)	45 (67.2)	5 (7.5)
I will use the skills I learned	0 (0)	3 (4.5)	14 (20.9)	46 (68.7)	4 (6)
Daily Growth helped me...					
parent with partner	4 (6)	17 (25.4)	23 (34.3)	21 (31.3)	2 (3)
manage parenting challenges	1 (1.5)	7 (10.5)	27 (40.3)	29 (43.3)	3 (4.5)
understand child's emotions	0 (0)	9 (13.4)	15 (22.4)	39 (58.2)	4 (6)
strengthen parent-child bond	0 (0)	9 (13.4)	26 (38.8)	30 (44.8)	2 (3)

[a]Due to a survey error, both ends of the acceptability scale were labeled "Strongly disagree," limiting interpretation of responses. It is possible that some participants selected "Agree" in place of "Strongly agree," since the latter option was not available. Few participants overall selected "Strongly disagree."

Descriptive Efficacy

Two-Week Post survey Outcomes

Descriptive statistics for the outcome measures are reported in Table 4. Internal consistency (Cronbach α) for most measures was similar to values reported in the original validation studies [63-66,68-75,81]. Multivariable regression analyses examining condition differences are also presented in Table 4. Two models were estimated for each outcome: an unadjusted model and a model adjusted for baseline values. Findings were largely consistent across models, with significant results differing only for overall parent emotion regulation. Specifically, the between-group difference in overall parent emotion regulation was statistically significant in the unadjusted model but did not remain significant after adjusting for baseline scores. Overall, results indicated greater improvements from baseline to 2-week postintervention in the intervention group than in the control group in parent emotion dysregulation, including nonacceptance of emotional responses, parent psychological distress, and parent negative affect. No significant improvements were evident for any child outcomes.

In-the-Moment Post-EMI Outcomes

Table 5 presents the linear mixed model regression analysis of post-EMI survey outcomes. Two models were estimated for each outcome: an unadjusted model and a model adjusted for corresponding pre-EMI values. Findings were consistent across both models, demonstrating a significant association between condition and momentary parent negative affect. No additional significant effects were found. Intraclass correlation values indicated that a small proportion of variance in outcome measures was attributable to individual differences.

Discussion

Principal Findings

This pilot randomized controlled trial evaluated the feasibility, engagement, and acceptability of a small-scale prototype of the Daily Growth parenting program, a digital intervention designed to provide in-the-moment support for parents using an EMI approach. Overall, the study met its recruitment target and demonstrated a high retention rate. Engagement with pre-EMI surveys exceeded expectations, translating to parents on average completing a survey once per day. Participants responded positively to the program and found the resources useful. However, post-EMI survey completion rates were lower than anticipated, with parents responding approximately 1 in 5 times, and certain demographic groups were underrepresented. Together, these findings offer valuable insights for refining the program and guiding future research.

Feasibility

This pilot study exceeded the recruitment target of 150 participants and retention rates were high compared with similar parenting interventions [20,82,83], indicating a high level of participant interest and engagement. This may be attributed to Daily Growth's user-centered design, including flexible and tailored support based on parent needs. Nevertheless, some attrition occurred between screening and baseline, as well as during the 2-week intervention period, highlighting opportunities to refine the enrollment process and strengthen engagement strategies. Engagement with pre-EMI surveys exceeded expectations. Overall, engagement with the daily prompts throughout the study period was at a similar level to other EMA or intervention studies [23] and close to the recommended rate of 80% [10]. Notably, the predefined engagement benchmark for this study was 50%, as Daily Growth is intended to be a light-touch, accessible program that would not be overly burdensome for busy parents. Achieving engagement levels substantially above this target therefore provides strong preliminary support for the acceptability of the delivery schedule. However, engagement with post-EMI surveys was lower than the target of 50% completion, which may be attributed to having separate online systems. As EMI survey prompts were delivered via email, while surveys and videos were delivered through Platform O, it is possible that once parents completed the pre-EMI survey and were directed to a video or website elsewhere, they did not return to their email to click on the post-EMI survey prompt. Using a smartphone app with push notifications could help streamline this process by keeping all prompts and resources within a single, integrated system. Additionally, providing onboarding instructions to emphasize the importance of completing all survey components may further support engagement. It is also important to note that technical issues affected the post-EMI surveys and should be addressed in future implementations.

This pilot study demonstrated Daily Growth's potential to engage a diverse group of parents, an ongoing challenge in online parenting intervention studies [20,84]. However, fathers, migrant parents, and parents with a low level of education were underrepresented, consistent with patterns in previous intervention research [20,82-86]. Fathers may perceive parenting programs as less relevant to them or feel that their contributions are undervalued, while migrant parents may face barriers such as language, accessibility, or differing cultural expectations [20,82-86]. Although the primary focus of this pilot was not on recruiting a representative sample but rather on testing the technical feasibility and engagement with the Daily Growth prototype, future iterations should aim to increase inclusivity by incorporating father-specific recruitment strategies and ensuring that program materials are broadly accessible to better reach underrepresented groups.

Acceptability

Participants responded positively to Daily Growth, with most finding the resources useful and willing to recommend the program to others. These findings suggest that the Design Mapping framework and EMI approach successfully enhanced parent satisfaction, consistent with previous studies finding these approaches acceptable [13,37,87-91]. Approximately half of the participants reported that the program fully met their needs or helped them manage parenting challenges, a reasonable outcome given the pilot offered only 10 videos covering 5 parenting situations. The full Daily Growth program, featuring 90 video resources across 3 program types, will address a broader range of parenting challenges and better accommodate diverse family needs. Participants also reported technical difficulties, particularly with post-EMI survey prompts. Improving technical infrastructure to streamline user experience and minimize disruptions remains a priority for future iterations.

Descriptive Outcomes

Descriptive outcome data were collected to test the feasibility of the program evaluation methods, more specifically to assess whether the measures are sensitive to change, whether outcome data can be collected completely, and whether the measurements are viable to use in a larger trial. The prototype version of Daily Growth showed significant reductions in momentary negative affect (EMI outcomes) in participants in the intervention condition compared with the control, suggesting that the program's real-time delivery may effectively support parents during challenging situations. These findings align with previous emotion-focused parenting interventions [92-95] and EMI-based parenting programs [13,37] and indicate that brief, targeted support can help parents manage their emotions more effectively. Furthermore, baseline to 2-week postintervention improvements in parent emotion regulation and mental health outcomes were observed, including reduced nonacceptance of emotional responses, psychological distress, and negative affect.

Notably, the between-group difference in total parent emotion dysregulation was significant in the unadjusted model but did not remain significant after adjusting for baseline scores. This likely reflects the strong stability of emotion regulation over time and limited statistical power in this pilot sample. Furthermore, no significant effects emerged for baseline to 2-week post survey child outcomes or broader parenting behaviors such as emotion coaching. The program was designed to target parent emotion regulation and parenting behaviors; hence, child outcomes represent more distal targets. Given the pilot's brief duration (2 weeks), limited intervention content

XSL•FO
RenderX

(only 10 of the total 60 videos were available), and small sample size, detecting changes in these outcomes was not the focus of the current trial. Child emotion regulation develops gradually through repeated parent-child interactions, and meaningful shifts in parenting practices typically require sustained exposure to intervention content. The full 6-week Daily Growth program, with substantially more content and longer intervention exposure, provides a more appropriate test of child-level impacts in a larger, adequately powered trial.

Implications for Future Research

Several directions for future research and program refinement should be considered. First, investigating how parent gender influences program efficacy warrants attention, as mothers and fathers often differ in their parenting approaches [96-98], suggesting opportunities for targeted tailoring. Second, although baseline parental mental health was assessed, this pilot study was not powered to examine whether feasibility, acceptability, or descriptive efficacy outcomes differed by mental health status. Future trials could explore mental health as a potential moderator of engagement and program effects, as these parents may have greater needs for support and may engage differently with EMI program delivery [99]. Furthermore, optimizing intervention timing deserves careful consideration. While in-the-moment delivery can be highly effective [29,100], some parents may be more receptive to learning new skills when not experiencing high emotional dysregulation [101]. Future research should systematically examine timing and delivery strategies that maximize both learning and immediate support, potentially offering parents flexibility when they access content.

Strengths and Limitations

This study makes several important contributions. The randomized controlled trial design minimizes bias and provides a robust test of full trial methods. Most notably, this represents one of the first applications of an EMI approach to digital parenting interventions. Beyond enhancing engagement through regular prompts, the EMI design generated valuable real-time data on parents' momentary experiences and immediate responses to brief video interventions. These findings provide early support for EMI's viability in early childhood parenting support and demonstrate that twice-daily prompts are generally acceptable to parents. However, several limitations warrant consideration. First, the pilot tested only a 2-week prototype, whereas the full program spans 6 weeks. While short-term feasibility was demonstrated, sustained engagement with twice-daily prompts over extended periods remains uncertain. Second, the sample, although adequate for pilot testing, was relatively small and underrepresented fathers, migrant parents, and those with lower educational attainment, limiting generalizability. A third limitation is that the prototype platform was not able to capture the number of resources watched by each participant, meaning that intervention exposure could not be quantified beyond the EMI survey data. Technical issues also affected data quality and user experience. Approximately half of the participants did not receive post-EMI survey prompts due to a programming error, and prompts did not account for time zones, resulting in some participants receiving surveys outside intended times. In addition, multiple completions of EMI surveys and missing participant IDs resulted in the exclusion of a portion of responses. These issues highlight the importance of refining the technical infrastructure prior to a fully powered trial. Finally, the limited intervention content (10 videos covering 5 situations) constrained our ability to detect changes in child outcomes or broader parenting behaviors, which likely require more comprehensive exposure to demonstrate effects.

Conclusions

Reaching diverse families and sustaining their engagement remains one of the greatest challenges for universal parenting programs. This pilot study demonstrates that delivering parenting support through an EMI approach is both feasible and acceptable. Testing a small-scale Daily Growth prototype, we found that brief, tailored video resources successfully engaged parents in real time. High recruitment and retention rates, combined with positive parent feedback and engagement exceeding expectations for pre-EMI surveys, provide compelling evidence that tailored EMI approaches can overcome traditional barriers to reach and engagement in digital parenting programs. However, low post-EMI completion rates indicate the need for refinements to reduce participant burden and improve response rates. These promising findings establish a foundation for a larger trial to rigorously assess efficacy, optimize delivery methods, and enhance accessibility for underrepresented groups, particularly fathers and migrant parents. Beyond demonstrating feasibility, this study advances digital parenting interventions through its innovative co-design approach. Daily Growth represents a new model for scalable, data-driven parenting support that has the potential to improve parenting practices and child mental health outcomes at a population level.

Acknowledgments

The authors thank all parents who participated in this study. Moreover, the authors thank Ainsley Summerton and Kayla Redpath for their valuable contribution toward the pilot study. This study was funded by an internal Deakin University Faculty of Health Research Capacity Building Grant Scheme (HAtCH) grant. The authors used generative AI tools, such as Claude or ChatGPT, to improve phrasing and readability, to help generate syntax or code, and to create a TOC image. All AI-generated output was reviewed by the authors, who take full responsibility for the accuracy of the manuscript.

Editorial Notice

This randomized study was retrospectively registered because at the time the study began, the authors were not aware of the requirement for prospective registration of pilot studies. The editor granted an exception from ICMJE rules mandating prospective registration of randomized trials, because the risk of bias appears low and the study was considered formative, guiding the development of the application. However, readers are advised to carefully assess the validity of any potential explicit or implicit claims related to primary outcomes or effectiveness, as retrospective registration does not prevent authors from changing their outcome measures retrospectively.

Abstract

Background: After hospital discharge, parents of preterm infants need accessible and reliable information to gain confidence and skills in their child-caring abilities and parental autonomy. Parental need for information after hospital discharge includes topics related to prematurity, such as crying, feeding, sleeping, infant care, general health, and neuromotor development. However, parents report difficulty in finding and understanding this information. Mobile apps have the potential to improve information provision.

Objective: The aim of this systematic app review was to (1) identify mobile apps for parents of preterm infants targeting the period after hospital discharge and (2) evaluate the content, quality of the app, and understandability and actionability of the information material.

Methods: We systematically searched for apps in the Apple App Store, Google Play Store, and Google, along with a literature search using PubMed. Multiple keywords were used (eg, “preterm baby,” “app,” and “home”). Apps were included when they provided information for parents on topics and content related to prematurity after hospital discharge. To examine app content related to the postdischarge period, apps were reviewed, and topics were identified. The Mobile App Rating Scale (MARS) was used to measure the app’s quality, and the Patient Education Materials Assessment Tool for Audiovisual Materials (PEMAT-AV) was used to measure the understandability and actionability of the information material.

Results: After the initial search, the titles and descriptions of 196 apps were screened for eligibility. Eventually, 9 English apps were included in the review. Information related to the postdischarge period constituted only a small part of the app’s content. Most commonly addressed topics related to the period at home were vaccinations, follow-up, feeding, and using home oxygen. Using the MARS, only one of the 9 apps received a good score for overall quality (“MyPreemie app”; Graham’s Foundation), and 7 apps received an acceptable score. Only 4 apps scored high on understandability of the PEMAT-AV, and 6 apps scored high on actionability. No Dutch apps were identified.

Conclusions: The current availability of mobile information apps for parents of preterm infants targeting the period after hospital discharge is limited. A total of 9 English apps were identified, which contained a small portion related to the postdischarge period. This content is not comprehensive for the postdischarge period: topics indicated as relevant by parents, such as crying in preterm infants, diaper change in preterm, or parental well-being after preterm birth, are often missing. The overall quality of the apps is only acceptable. Although the reliability of the information was close to good, the understandability of the apps was moderate. Recommendations for future app development include more relevant and understandable information related to the postdischarge period, which meets the demand of parents of preterm infants.

Introduction

Yearly, 13.4 million babies are born preterm (PT; <37 weeks of gestation), of which 2 million infants are born very preterm (VPT; <32 weeks of gestation) [1]. VPT infants are frequently discharged from the hospital before their term date [2], and parents often feel inadequately prepared to take their vulnerable infant home [3]. Without the continuous professional support of the neonatal intensive care unit (NICU), parents lack confidence or competence in infant caregiving. Parents report practical, emotional, and financial challenges at home and the need for practical support regarding baby caregiving tasks, feeding, medication, or managing unexpected health issues [4]. The uncertainty about the health, growth, and neuromotor development of their VPT infant can heighten parental anxiety and negatively affect parents' caregiving behavior [5]. Parental confidence and competence in caring for their VPT infant can be increased by professional support and tailored information, and is thus an important approach to improve parental and infant outcomes [6,7]. Caring for a VPT infant after hospital discharge can be more demanding for parents than caring for a typically developing infant. VPT infants show different behaviors, such as reduced activity, alertness, and responsiveness, that require specific parenting skills to interpret their baby's cues [4]. Parents therefore require information on common topics specifically targeting prematurity, such as crying (how to comfort a preterm infant), feeding (how and when to transition to solid foods), sleeping (recognize pattern of sleep and fatigue in their baby), infant regulation (help their baby to regulate), infant care (diaper change in a very small infant), general health (when to contact a pediatrician), and neuromotor development (differences in milestones between term and preterm infants) [5,8]. This information, specific to premature infants, is, however, not available on the internet [6]. Parents appreciate that general parenting websites provide accessible information on newborn topics such as feeding and digestion, but the content is perceived as less appropriate for parents with a VPT infant [6]. Therefore, practical and tailored information is necessary to increase knowledge and skills to support parents to feel confident in taking care of their preterm baby at home. To accommodate their underlying emotional needs, parents prefer information that is strength-based and confirming or reassuring in their caregiving [8].

Almost all parents in the NICU use their smartphones to search for information regarding prematurity on the internet [9]. For instance, in the Netherlands, information is provided by the Dutch parent organization (Care4neo) [10]. Facilitated by the ease of use, the 24/7 availability, and the ability to make information attractive, mobile health (mHealth) apps are promising tools to provide health information [11]. In general, parental knowledge about infant development is associated with better caregiving behavior and improved infant development [12]. Mobile apps have the potential to improve parental well-being and parenting in the perinatal period [13]. mHealth apps vary in quality, but many are of moderate quality or out of date [11,14]. A previous review on information apps targeting parents with an infant who was still admitted to the NICU showed that only a quarter of the apps for parents were considered of good quality [15]. For optimal support, parental needs for information should be incorporated in the content of the app [16]. Parents have ongoing information needs, but what they want to know changes over time [8]. After discharge home, when hospital staff support is lacking, parents need different information to feel competent in their caregiving than during their initial hospital stay.

For health care professionals and parents, it is important to be able to use high-quality apps, include engagement, functionality, aesthetics, and information quality. Therefore, the information content of mHealth applications needs to be understandable for all parents, irrespective of health literacy levels. Since preterm birth has been consistently associated with lower socioeconomic status [17], low health literacy is also a prevalent issue in parents of VPT infants. Health literacy refers to the skills needed to function effectively in the health care environment [18], and low health literacy is associated with poorer use of health care services and poorer health outcomes [18]. Parents with lower health literacy may encounter difficulties in obtaining, processing, using, and interpreting information in mHealth applications [19]. To benefit from mHealth, parents require digital health literacy skills, such as using digital devices, searching for and understanding information, and evaluating the validity of the information [20]. However, to date, little is known about the quality, understandability, and actionability of available mHealth apps designed to support parents of VPT infants after hospital discharge. Therefore, the aim of this app review was (1) to identify mobile information apps for parents of preterm infants targeting the period after hospital discharge and (2) to evaluate the content, quality of the app, and understandability and actionability of the information material.

Methods

Study Design

This systematic review of mobile apps followed systematic review methodology adhering to PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) standards [21] (Multimedia Appendix 1) and published conduct and reporting recommendations for systematic app store reviews [22].

Search Strategy

To ensure the identification of relevant mobile apps, a comprehensive search was conducted, using 4 different strategies. Apps were directly searched in (1) Apple App Store for iOS and (2) Google Play Store for Android. In addition, mobile apps were also searched via (3) Google and (4) PubMed. The search in the app stores and Google was performed in December 2023. The search in PubMed was performed in May

XSL•FO
RenderX

2022. In the first 3 search strategies, keywords were used both in Dutch and in English.

The different search machines implied different search strategies. In the app stores, separate key terms (in Dutch and English) were used in the search field: “preterm baby,” “preemie,” “premature,” “NICU,” and “discharge.”

For the Google internet search, the term “app” was always used and combined with terms “preterm baby,” “preemie,” “prematurity,” NICU,” “Neonatology,” and “incubator.”

The PubMed search combined terms “parent,” “mother,” “father,” or “caregiver” AND “premature birth,” “premature infant,” “preterm,” “prematurity” AND “mobile application*,” “smartphone application*,” “health app*,” “mobile app*.” No MeSH (Medical Subject Headings) terms were used for the PubMed search. The aim of the Google internet and PubMed search was to identify more apps that were subsequently retrieved from one of the App Stores.

The search in the Apple App Store and PubMed provided a certain number of apps and papers. These were all reviewed for eligibility. In the Google Play Store, the search yielded a continuous stream of apps, many of which were not relevant to our inclusion criteria. Therefore, we limited the screening to the first 50 apps that were displayed in the search results. These are typically ordered by relevance and popularity and align with how parents would conduct such a search. In the Google web search, the first 2 pages of results were reviewed to evaluate whether an app for parents of preterm infants was described. The search ended when 2 pages did not contain new hits. Limiting search results is a common practice in app and website reviews, as later results are less likely to be accessed by parents, often align less with the search criteria, and parents are unlikely to continue their search beyond a certain point [11,15,23].

App Selection

Several inclusion and exclusion criteria were used to select the mobile apps (Table 1). The free-of-charge criterion was used because we wanted to ensure that apps were available to all parents regardless of their socioeconomic status, income, or willingness to pay for a mobile app.

Table 1. Inclusion and exclusion criteria for app selection.

Condition	Inclusion criteria	Exclusion criteria
Topic	VPT[a] infants	Typical developing infants
Timing of information	Period after hospital discharge	Only during hospital stay
Language	English or Dutch	Other languages than English or Dutch
Access	No access code	Access code required
Information in the app	Directed to parents	Not directed to parents
Download	App available for download	App not available for download
Charge	App is free of charge	Paid app

[a]VPT: very preterm.

After removing duplicates between the two app stores, the Google and PubMed search, the app descriptions and features were first screened in the Apple App Store or Google Play Store by one researcher (RG) and discussed within the research team for eligibility. Apps that fulfilled the inclusion criteria were then downloaded. Two reviewers (RG and MJ-V) screened the apps for inclusion in the full app review and discussed the eligibility within the research team.

Data Extraction and Quality Assessment

For each app, the following data was collected: name of the app, operating system, developer and its affiliation, language, target population, year of last update, and a brief description of the app. To evaluate the postdischarge hospital content, a list of topics per app was created. To evaluate the quality of the apps and the understandability and actionability of the information material, two independent reviewers (MJ-V and RG) trained themselves to use the Mobile Application Rating Scale (MARS) [24] and the Patient Education Materials Assessment Tool for Audiovisual Materials (PEMAT-A/V) [25]. Thereafter, all included apps were independently evaluated by the two reviewers, and disagreements were resolved until consensus was reached. When no consensus was reached, the research team was involved. For each instrument, a structured data retrieval form was composed, using a spreadsheet in Microsoft Excel.

MARS

The MARS is a tool for assessing the quality of mobile health apps. The MARS consists of 4 objective scales: “engagement” (5 items: fun, interesting, customizable, interactive, and well-targeted to audience), “functionality” (4 items: app functioning, easy to learn, navigation, and gestural design), “aesthetics” (3 items: layout, graphics, and visual appeal), and “information quality” (7 items: accuracy of app description, measurable and achievable goals, quality of information, quantity of information, visual information, credibility, and evidence-based). Each item is rated on a 5-point rating scale, ranging from 1 “inadequate” to 5 “excellent.” Each item has specific descriptions for these rating anchors. Some items have the option “not applicable”. In addition, there is one scale for “subjective quality” (4 items: recommendation of the app, estimated frequency of use, willingness to pay, and overall star rating of the app). The first 3 items are rated on a 5-point scale, and the last item on a 3-point scale. The overall mean score for the 4 objective subscales is calculated, excluding the items rated

XSL•FO
RenderX

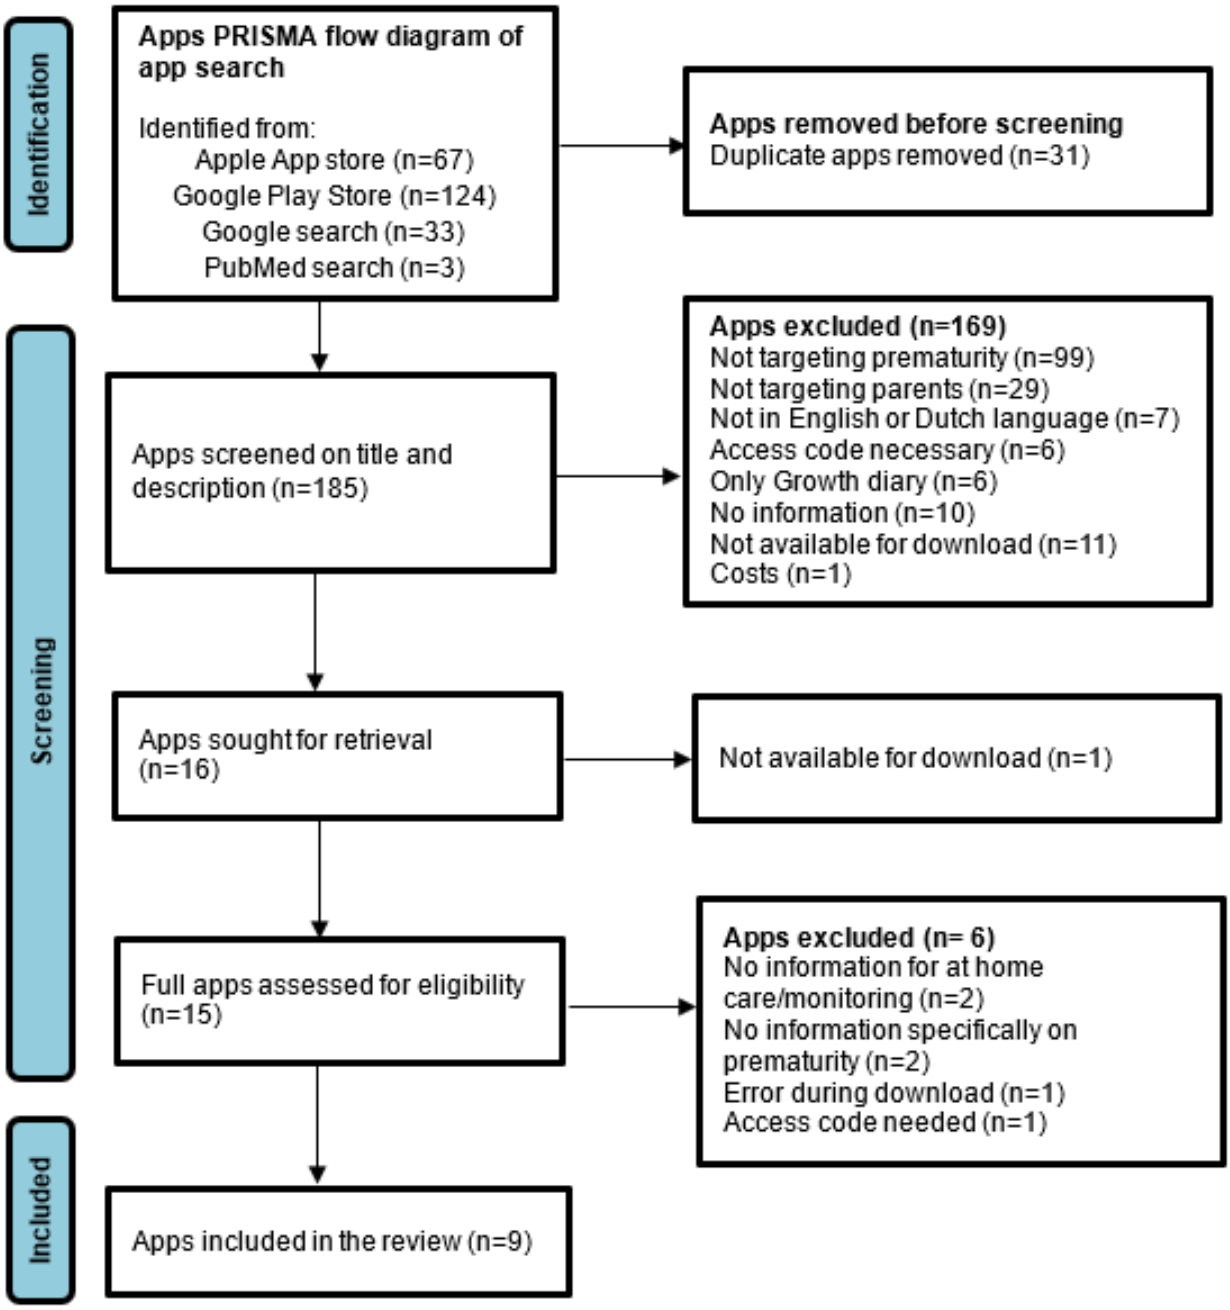
as not applicable. The MARS has a high internal consistency (α=.90) and high interrater reliability (intraclass correlation coefficient [ICC]=0.79) [24]. For this study, we used the Dutch version of the MARS [25].

PEMAT-A/V

The PEMAT-A/V is an instrument that assesses the understandability and actionability of audiovisual patient education materials [26]. The PEMAT-A/V consists of 2 scales: understandability (13 items) and actionability (4 items). Understandability is defined as the ability of people from diverse backgrounds with varying levels of health literacy to comprehend educational material and extract key messages. Actionability is defined as the ability of learners to identify what actions can be taken on the basis of educational material information. Understandability includes 19 items evaluating the content, word choice and style, number usage, organization, layout and design, and use of visual aids. Actionability contains four items and evaluates whether the material (1) identifies an action the user can take, (2) the user is directly addressed, (3) breaks down an action into manageable steps, and (4) explains how to use the charts, graphs, tables, or diagrams to take action. Items are rated with “disagree” (0 points) or “agree” (1 point). Some items have the additional option “not applicable.” The PEMAT-A/V is designed to be completed by professionals and helps them select education material that is understandable and actionable. The PEMAT-A/V items are based on other instruments and concepts for developing educational material and are reliable for raters not trained in the use of the PEMAT-A/V. The researchers read the information in the apps and considered each item from a parental perspective, specifically a parent with low health literacy skills. The researchers did have experience with developing information for people with low health literacy skills. The scores for the two scales are calculated as a percentage, ranging from 0-100. A higher score reflects more understandability or actionability. An expert panel established the face and content validity. Interrater reliability was moderate according to Cohen κ (0.50), but with a high absolute agreement of 80% and high agreement when calculated by Gwet agreement coefficient 1 (0.71). Internal consistency was strong (Cronbach α=0.76), and the average item-total correlation=0.62. Construct validation was established based on differences in actionable and poorly actionable material, as well as a strong negative correlation between grade level and both consumer-testing results and PEMAT-A/V scores [26].

Data Analysis

Data analysis was performed using IBM Statistical Package for Social Sciences software (IBM SPSS; version 26). The MARS item scores were averaged for the engagement, functionality, aesthetics, and information subscales. These scores for app quality were then averaged, creating a mean (SD) app quality score. Descriptive statistics were used to summarize the results of the MARS and the PEMAT-A/V. To evaluate consistency between raters, the ICC between the raters was calculated for the MARS and the PEMAT-A/V. Rater agreement was examined by ICC based on a 2-way mixed-effects model. An ICC of <0.50 is considered poor, 0.51-0.75 as moderate, 0.76-0.89 as good, and >0.90 as excellent.



Results

Search Results

The search yielded 191 apps in the Apple and Google Play stores, and additionally 36 apps in Google and PubMed. After removing duplicates, 185 apps remained (Figure 1). Based on the title and description in the app stores, 169 apps were excluded. The majority of the excluded apps did not contain information on preterm-born infants (n=99; 58%), did not target parents but health care professionals (n=29; 17%), or did not contain information, but for instance only growth diaries (n=6; 4%). Only one app was excluded because it was a paid app. A total of 12 apps (6%) that were identified via Google or PubMed could not be retrieved anymore in the app stores. The remaining 16 apps were downloaded and screened for inclusion in the full app review. One app was not available for downloading. Finally, 9 apps fulfilled the inclusion criteria and were included in the final analysis. The majority of the apps were available in both app stores (n=5), 3 apps were only available in the Apple App Store, and 1 app was only available in the Google Play Store. In addition, 2 apps were also described in a scientific paper. One paper describes the content of the MyPreemie app, based on an earlier book, Preemies: the Essential Guide for Parents of Premature Babies, supplemented with new tools [27]. The co-design approach of the Preterm Connect app has been described across 3 settings with different social, economic, and cultural participants [28]. The preliminary findings show similar parental needs, but different preferences across the study populations.

XSL•FO
RenderX

Figure 1. PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) flow diagram of search for apps for parents of preterm infants after hospital discharge.

Characteristics of the Apps

The apps were developed in the United States of America (n=4; A2, A4, A7, and A9), the United Kingdom (n=2; A3 and A5), Australia (n=1; A6) and New Zealand (n=1; A1), and South Africa (n=1; A8; Table 2). All 9 apps were in English; no Dutch apps fulfilled the inclusion criteria. One app (A2) had information in 25 languages, and another app (A4) was also available in Spanish. The apps were developed by reputable sources, including hospitals (n=4; A1, A3, A6, and A7), nongovernmental organizations (n=3; A2, A4, and A5), and universities (n=2; A8 and A9). The last update of the app varied between 3 weeks and 3 years, with the majority of the apps updated more than a year ago. The size of the apps varied between 7.2 and 102.2 MB. In addition, 3 apps were downloaded more than 1000 times (A1, A2, and A4) and received positive ratings ranging from 4.0 to 4.9 on a scale from 0-5.

App Content

Most of the information in all apps was directed to the period in the NICU. The quantity of information for the posthospital discharge period was limited. Some apps have one “chapter” that covers the postdischarge period (A5, “at home with baby;” A9, “Parenting at home”), whereas other apps have subthemes within a chapter (A4, “Preemie Parenting” and “going home”). Topics that were addressed varied widely between the apps (Table 3). The most common topics that were covered in the apps related to the period post discharge were: vaccinations, follow-up, and recognizing signs of illness. More practical information was provided on feeding, using home oxygen, and sleep (Table 3). Less often, the apps provided information on aspects that were reported as relevant by parents [5,8] as diaper change (A5 and A9), crying (A1, A7, and A9), or parental well-being (A4, A5, and A9).

Table 3. Most common postdischarge topics and functionalities of the apps.

App content	Number of apps	App IDs
Common topics post discharge		
Feeding	7	A2, A3, A4, A5, A6, A8, and A9
Vaccinations	6	A1, A2, A3, A4, A5, and A9
Follow-up	6	A1, A3, A4, A5, A8, and A9
Signs of illness in a baby	5	A1, A2, A7, A8, and A9
Sleep	5	A1, A3, A5, A7, and A9
Home oxygen	4	A3, A4, A5, and A7
Bathing	4	A5, A6, A7, and A9
Functionalities		
Monitoring or tracking (diary, growth, and weight)	3	A4, A5, and A6
Making notes or saving questions	3	A4, A5, and A7
Sharing information	3	A2, A4, and A5
Saving articles	3	A1, A2, and A9
Community groups	1	A9

Besides information provision, the apps also included other functionalities, including monitoring and tracking of infants' weight and height, amount and duration of feeding, or parental mood (A4, A5, A6, and A7; Table 3). The option of making notes was also provided by 4 apps (A3, A4, A7, and A9). Sharing information from the app with others was available in 3 apps (A2, A4, and A5). Community groups were only incorporated in a single app (A9).

Quality of the Apps (MARS)

The interrater reliability of the MARS of the two raters was high (ICC=0.99, CI 0.98-0.99). The overall mean quality (range 0-5) of the 9 apps was 3.4 (SD 0.5; range 2.3-4.3; Table 4). The majority of the apps (n=7) scored between acceptable to good, one app (A7) scored below acceptable, and only one app (A4) scored above good. There was a difference in the ratings between the 4 objective MARS scales. Engagement was rated as poor to acceptable (mean 2.8, SD 0.6; range 1.8-3.4), specifically due to low scores on entertainment, customization, and interactivity. The aesthetics domain was acceptable (mean 3.2, SD 1.0; range 1.7-5). Information quality and functionality were close to good (mean 3.8, SD 0.6; range 2.3-4.3), and (mean 3.9, SD 0.5; range 3.3-4.8), respectively. Several apps received a good score (>4) for information quality (A2, A4, A5, A6, and A9), functionality (A2, A3, A4, and A8), aesthetics (A4 and A6), and overall mean quality (A4). None of the apps received a good score for engagement. The subjective quality (total range 0-18) ranged from 8 to 16, with a mean of 12.6 (SD 3.0). A total of 7 apps (A1, A2, A3, A4, A5, A6, and A9) received a good score for subjective quality.

Understandability and Actionability of the Apps (PEMAT-AV)

The interrater reliability of the PEMAT-AV between the two raters was high (understandability ICC=0.89, 95% CI 0.55-0.98; actionability ICC=0.91, 95% CI 0.59-0.98). The mean understandability of the apps was 78% (SD 12%), ranging from 55% to 100% (Table 4). Only a single app (A2) scored the maximum of 100% for understandability. Lower ratings were obtained when lacking a summary of the information or visual cues to draw attention to key points. The mean actionability was 85% (24%; range 33% to 100%). Lower ratings were obtained when not addressing the user directly or not breaking the action down into manageable, explicit steps. A total of 6 apps (A2, A3, A5, A6, A7, and A9) received the maximum score of 100% for actionability.

Discussion

Principal Findings

This app review provides insight into the availability, content, quality of the apps, and the understandability and actionability of the information material for parents of preterm infants after hospital discharge. A total of 9 apps were identified that provided information after hospital discharge, but the amount of information on the postdischarge period was limited in all apps. Only one app was of overall good quality, while the mean overall quality was between acceptable and good. The understandability and actionability of the apps were respectively moderate and good.

Although our inclusion criteria focused on the postdischarge period, the apps in this review contained primarily information for the NICU period. The lack of high-quality and understandable apps found in this review is in contrast with the needs of parents of VPT infants after hospital discharge. Parents of VPT infants have reported challenges when they are at home regarding the availability and usability of information [8]. For parents who struggle to seek information, finding an app with appropriate and reliable content will be even more difficult, particularly for those with low health literacy skills [29]. Health care professionals, such as nurses, pediatricians, or pediatric physical therapists, have a responsibility to support parents in their search for relevant and reliable information during their hospital stay. As parental competence was found to decrease after discharge home, it is an important strategy to improve parental confidence in taking care of their VPT infant [30]. When parents and infants are at home, without direct access to a health care professional, apps have the potential to provide health information to parents and can be accessed when and where needed.

Mobile apps can, however, not replace in-person care. Effective use of apps requires guidance from health care providers, as combining digital tools with professional support has been shown to enhance parental confidence [31]. This is even more important for parents with limited health literacy or digital literacy, who are at higher risk of misunderstanding or misapplying information [18,19]. Our findings confirmed that the understandability of many apps is limited, largely due to complex medical terminology and text-heavy formats. This can particularly exclude parents with low health literacy, widening the existing digital divide [32]. Improving understandability, for example, through audio, video, simplified language, and multilingual options, along with professional support, is essential to make apps usable and effective for all parents.

Apps that cover both the period in hospital and after discharge can be beneficial to parents by providing relevant information throughout the different phases. In a previous review of 18 apps in the NICU context [15], only 5 were included in our review, indicating that most NICU apps do not cover topics post-discharge. There was variability in the amount of postdischarge information, the topics, the emphasis within the topics, and how the information was presented. Unfortunately,

XSL•FO
RenderX

the topics do not seem to correspond with the information needs of parents upon discharge [5,8], such as daily infant care, neuromotor development, as well as the impact of prematurity on parents. Instead, most topics are focused on vaccinations, follow-up, and using home oxygen.

Despite the use of Dutch search terms, no Dutch apps were retrieved in the App stores that fulfilled the inclusion and exclusion criteria. The Dutch apps that were found in the Google search were no longer available in the Google Play Store or Apple Store. The majority of the apps evaluated in this review were last updated over one year ago. This lack of updates is in line with a scoping review about problems and barriers related to the use and implementation of apps [33] and, consequently, impedes usability and user experience, which ultimately affects the effectiveness of applications. Apps without active maintenance quickly become outdated due to evolving technology, guidelines, and operating systems [34]. This underscores the necessity of a viable business model and continuous refinement and maintenance after initial development [35]. Sustainable funding for apps is essential, but there are currently few resources available. Partnerships between industry and research may offer a possible solution for some apps.

Only one app had good overall quality, whereas the mean overall quality of the apps was merely acceptable. This is in agreement with an earlier app review, where the mean overall quality was also acceptable [15]. Specifically, aspects within the domains of engagement and aesthetics could be improved. The apps scored particularly low on the engagement domain of the MARS, lower than acceptable. This subscale assesses whether the app is fun, interesting, customizable, interactive, and well-targeted to the audience. Lack of engagement is a common barrier related to the use of mHealth apps and is associated with low adherence [33]. Different functionalities can facilitate parental engagement with an app. A low rating on the Engagement domain suggests improvements are needed. Increasing engagement through entertainment appears not suitable for an app that provides information related to prematurity. However, the app could be customizable or interactive, and should certainly be well-targeted to the audience. If not, this latter aspect would certainly hinder the use of the app. A positive finding from our review was that the domain “information quality” of the apps was close to good. Reliable information is important as it may decrease parental stress and support better caregiving behavior [12]. This also matches the parental needs for reliable information and is probably a result of the reputable sources (hospitals and universities) that developed the apps. This is in contrast with two previous studies in which only 31% and 40% of the websites provided accurate and reliable information for parents of premature babies [6,11].

The understandability of the apps was scored as moderate, largely due to the primarily text-based information, indirect communication with users, and frequent use of medical terminology. In contrast, the app Birth and Beyond (Global Health Media Project) circumvented this problem by using only videos, in multiple languages. During stressful periods, such as hospital discharge, information should be presented in a clear and accessible manner, particularly for parents with low health literacy. For these individuals, the digital divide can be further exacerbated when the information is difficult to comprehend. The hospitals, universities, and nongovernmental organizations create apps with reliable information, but it may not be easily understood by all users. To meet the informational needs of all parents, apps need to be more understandable. Co-design that incorporates both health care professionals’ and parents’ perspectives can enhance app understandability by identifying the preferences and needs of the target group [34]. Reducing text, written at accessible reading age levels, using multiple languages, and incorporating audio and visual formats may improve understandability.

Only 2 papers were retrieved that described the development of an app [27,28], indicating a general lack of transparency about co-creation. None of the 9 apps have been assessed for their impact on parental outcomes. A study on the NICU2HOME app (CF Garfield) [31,36] showed that parental self-efficacy and satisfaction with care improved in parents of preterm infants. This mobile app has not been included in this review, as an access code was required. More research is needed to evaluate the use of apps, parental satisfaction, and the effects of app use on parental outcomes.

Limitations

First, only English and Dutch apps, free and without an access code, were included in the search, thereby possibly missing potential relevant apps. Second, other online resources that provide information to parents, such as websites, were also excluded. Also, progressive web applications were not captured in our search, as these are not available in the searched app stores. Third, the search for apps is time-dependent. Some apps are only available for a short time in the app stores, and replication of the search is therefore difficult. This became clear when apps identified through Google or PubMed were not available in the app stores. During the initial screening of app descriptions and features, followed by a secondary screening for inclusion, app content has been checked to decide whether it also contained information related to the postdischarge period. Fourth, it may be possible that apps have been excluded during the initial screening because the description did not refer to information related to the postdischarge period. However, this information was then likely not substantial and would also not appeal to parents. Fifth, the assessment of the quality of the apps and the understandability and actionability of the information material has been done by the MARS and PEMAT A/V. These are validated tools used by professionals. The researchers were familiar with the parental needs for information [8] and did consider the parental perspective during the evaluation of the apps. However, direct information from parents of a preterm infant has not been taken into account. As parents are the key users, their experiences are most valuable, and their engagement is important to ensure the content meets their needs. A next step would be to include parents to evaluate their experiences with good-quality apps. Finally, although it was evident that information on the postdischarge period was limited, we did not quantify the amount of information provided in the apps. Topics on postdischarge information were identified using a checklist and compared to previously recognized parental needs for information. While the lack of information on the posthospital discharge period was apparent, no specific

XSL•FO
RenderX

measurement was conducted to assess the extent of information for the hospital or home environment. Furthermore, an assessment of the relevance of the topics was also lacking. Future work may establish new methods to incorporate these aspects.

Recommendations

During the post hospital-discharge period, parents of preterm infants need evidence-based, reliable, and practical information. Mobile apps have the potential to offer this information in an accessible way. Currently, few good quality apps exist that contain reliable and understandable information, as the My Preemie app or Preterm Connect. However, more relevant information that matches the needs of parents of VPT infants after hospital discharge is necessary. Future development of digital support tools should also consider solutions that bridge the gap between in-hospital and at-home care by extending access to apps currently limited to the NICU setting. Co-design with parents has been shown to improve the relevance and understandability of health apps [37]. We not only recommend that future apps should be developed or adapted in co-creation with end users, but also that the development process is clearly reported. Research into the use and satisfaction of the parents should establish what information is key for parents, as well as how to deliver this information. In addition, the accessibility and understandability of an app need to be evaluated among parents with a preterm-born infant. The next step would be to evaluate the effect of the information app on parental outcomes as parenting skills, knowledge, and confidence.

Conclusion

The current availability of mobile information apps for parents of preterm infants targeting the period after hospital discharge is limited and not in line with the high parental demand. A total of 9 English apps were identified containing information on the postdischarge period. However, the apps contained limited content for the period at home. The overall quality of the apps was just acceptable, but the information quality was close to good. The understandability of the apps was moderate. Developing apps in co-creation with the end-users to better match their needs and increase the understandability is recommended.

Acknowledgments

No generative artificial intelligence tools have been used in any portion of the manuscript.

Data Availability

The datasets generated and analyzed during this study (ie, the MARS and PEMAT scores from two independent reviewers) are available in the Figshare repository [38]. The mobile apps assessed in this review are publicly accessible via the Apple App Store and Google Play Store.

Abstract

Background: While family-centered rounds are considered the standard of care, coordinating the presence of all stakeholders without knowing when the medical team will arrive can make their implementation challenging. To address this barrier, we created novel software, Q-rounds, that is integrated into the electronic health record and creates a real-time rounding queue that updates nurses and family members on medical team rounding time and allows families to join in person or remotely via phone. A previous observational study showed that the implementation of Q-rounds in a neonatal intensive care unit (NICU) led to increased nurse and family presence.

Objective: This study aimed to understand clinicians' perceptions of the use of Q-rounds on NICU rounding practices, such as the impact on rounding efficiency and clinician satisfaction, as well as facilitators and barriers in its implementation.

Methods: Q-rounds was implemented in the NICU at M Health Fairview Masonic Children's Hospital in May 2023. In this survey study, surveys were distributed to physicians, advanced practice providers, and nurses 6 weeks before implementation and 6 weeks afterward to collect data on the impact of Q-rounds on family-centered rounds. Data were analyzed both quantitatively and qualitatively.

Results: There were 118 respondents in the preimplementation phase and 110 in the postimplementation phase. After implementation of Q-rounds, clinicians perceived an increase in nurse presence ("most" or "almost all of the time" n/N= 48/105, 46% to n/N=24/36, 75%; *P*<.001) and family presence (at least "sometimes" n/N=45/106, 46% to n/N=35/36, 97%; *P*<.001) on rounds. Respondents perceived rounds as more efficient (n/N=56/105, 53% to n/N=27/36, 75%; *P*=.006), and more respondents indicated being satisfied with rounds (n/N=59/105, 46% to n/N=62/84, 74%; *P*=.003). There was no perceived difference in rounding duration. These findings were supported by thematic analysis of open-ended responses.

Conclusions: A novel virtual rounding queue software that notifies families and nurses of when to expect the rounding team was associated with increased clinician perceptions of efficiency, participation in rounds by nurses and families, and satisfaction with rounds.

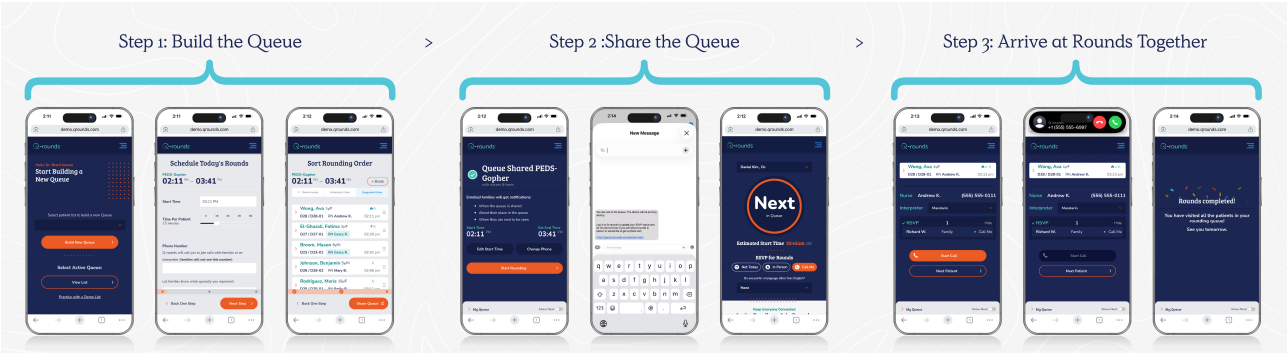
Introduction

Study Background

The practice of multidisciplinary family-centered rounds (FCRs) is considered standard practice by the American Academy of Pediatrics [1,2]. FCR entails the care team, including physicians, trainees, bedside nurses, and other staff (eg, dieticians, respiratory therapists, and interpreters where needed), along with the family or caregivers, working together to set the daily plan of care. Ample evidence supports the benefits of FCR, with

XSL•FO
RenderX

previous studies showing improvements in health care team communication [1,3-6], increased participation and decision-making of patients and families [7,8], increased family confidence in the health care team [7], improved patient safety [1,5], improved perception of teaching [5], and improved rounding efficiency [1]. Furthermore, FCR in the pediatric setting has been found to increase "humanistic outcomes" in trainees, including empathy, partnership, and respect [6].



Despite these known benefits to FCR, there are many barriers to implementation. Practically speaking, no matter how impactful FCR is, the improved outcomes can only be realized if the nurse and family are able to be present for rounds. In a scoping review on FCR's implementation, the study by Knighton and Bass [2] reports that the "scheduling challenges for nurses, families, and others that want to attend rounds but may not have the flexibility needed because of important competing demands" is a significant barrier to implementation. Without knowing when to expect the team to arrive for a given patient, nurses are unable to plan for attendance or may be asked to drop what they are doing to join. Families often must choose between work or other obligations or sitting at the bedside for hours waiting their turn for rounds [9]. Additional barriers exist for families who communicate in languages other than English [2], which often has its own scheduling and logistics challenges [2,9]. Additionally, some medical teams are hesitant to implement FCR because of concerns regarding FCR taking more time than traditional rounds and potentially negatively affecting trainee teaching.

Other institutions have implemented static interventions to address scheduling barriers to FCR with some success, although they have their limitations. For instance, the study by Bekmezian et al [3] described implementing a rounding coordinator to complete the schedule and communication regarding rounding appointments and reported that this approach increased nurse attendance on rounds and resulted in positive feedback from patients and families. Other groups have implemented a rounding checklist to increase family participation [10] or have found providing a fixed rounding schedule before rounds began to be beneficial for increasing nurse and family presence [11,12]. Only 1 study addressed interpreter attendance [3], while many studies do not include patients or families who speak a language other than English. While it is promising that the barriers to FCR could be overcome, many of these strategies are prohibitively labor-intensive. Additionally, the use of a fixed rounding schedule also does not address the unpredictability of rounds, with often changing schedules as acute medical issues come up that need to be addressed.

Preliminary Studies

This software was first implemented in our medical center's neonatal intensive care unit (NICU). In an observational study comparing preimplementation and postimplementation of Q-rounds software (Figure 1), nurse and family attendance significantly increased without affecting the duration of rounds, with parent attendance increasing by over 100% [13]. However, this previous observational study did not address feedback from important members of the medical team, such as nurses, and the impact of the software on their experience with FCR. As the software was implemented, outcomes (eg, attendance of rounds by the key personnel, round planning, and efficiency) were incorporated in the deployment of the tool to capture the intervention's impact and sustainability [14].

Figure 1. Overview of the workflow of the Q-rounds software.

The physician or advanced practice provider starts by building a rounding queue based on anticipated clinical needs. They first estimate the rounding time for each patient. Next, the health care professional shares the rounding queue with the electronic health record (EHR) for other team members to view. The program calls nurses and texts the patients' families to provide their patient's spots in the rounding queue. When the rounding time for the patient arrives, the care team members and families are reminded to join. A phone call is automatically started if families reply requesting a phone call.

The purpose of this study was to understand and compare clinicians' (including physicians, nurses, and advanced practice providers) perspectives and experiences (such as the impact on rounding efficiency, clinician satisfaction, trainee teaching, as well as facilitators and barriers in its implementation) about rounding before and after implementing Q-rounds to better facilitate multidisciplinary FCR. We hypothesized that providing real-time notification of care team members and families about the expected rounding times would lead to improved experiences and efficiency, without affecting the availability of teaching time for learners.

Methods

This was a single-center survey study. We used a research design using quantitative analysis of survey results, supported by qualitative analysis of open-ended survey questions.

XSL•FO

Ethical Considerations

This study was reviewed and approved by the University of Minnesota Institutional Review Board (IRB-STUDY 00017619), and the IRB determined that this study involves no greater than minimal risk. Researchers who developed the software (MBP and JS) had conflict of interest policies managed by the University and were not allowed to access raw data.

Settings

The study took place in the M Health Fairview Masonic Children's Hospital 68-bed level IV NICU. Surveys were distributed in two 6-week phases: preimplementation (February 6, 2023-March 20, 2023) and postimplementation (June 14, 2023-July 27, 2023).

Rounds occur each morning and involve the clinical teams (attending, fellow, and resident physicians or advanced practice providers) working from a conference room. In addition to the attending physician and residents or advanced practice providers, the teams typically include a pharmacist, a dietitian, and sometimes a neonatology fellow. Before Q-rounds implementation, 1 team member would find or call the nurse for a patient when they were ready to round, and the nurse would bring the family with them if they were present in the room. This summoning to the conference room rounding approach is used in this setting for privacy, as there are shared patient rooms, preventing discussions at the bedside.

Study Design

We developed a Research Electronic Data Capture (REDCap; Vanderbilt University) survey to elicit perceptions of nurse and family member presence on rounds, rounding length of time and efficiency, clinician communication, and trainee teaching experience, as well as participants' demographics and roles. We had a mix of question styles including closed-ended multiple-choice questions, 5-point Likert-style questions, and open-ended questions. Likert scale questions included anchors of agreement (1 "strongly disagree" to 5 "strongly agree"), satisfaction (1 "very dissatisfied" to 5 "very satisfied"), or temporal assessment (1 "almost never" to 5 "almost always") depending on the prompt. The survey used branching logic to present relevant questions to physicians, advanced practice providers, and nurses, with several common questions being asked from both groups. The number of questions ranged between 15 to 25 depending on the branching logic used. Each question asked the respondent to reflect over the last week when providing an answer. In the postimplementation survey, there were additional open-ended questions asking about perceptions of the implementation of the Q-rounds software. We expected that it would take approximately 10 to 15 minutes to complete the survey.

Participants

All nurses, advanced practice providers, attending physicians, and trainee physicians (resident and fellow physicians) who work in the NICU were eligible to participate in the study. Participation was voluntary and anonymous, with no link to their email or other identifying information. In the instructions for the survey, people were instructed to take it only once, that is, 1 survey per 2-week period *within each phase* of the study.

Intervention or Exposure

The intervention being evaluated in this study was the implementation of the Q-rounds software described in detail in the background section above. When a patient was admitted to the NICU, the nurse asked the family if they wished to receive SMS text message updates about when to expect the medical team for rounds. If they indicated yes, the nurse would indicate so in a flowsheet in the EHR, which would enroll the family in Q-rounds and they would subsequently receive notifications about rounding time and the ability to RSVP to join in person or remotely. Regardless of whether or not the family opted in to enroll, nurses would still receive notifications of rounding time. The electronic survey was created using REDCap tools hosted at the University of Minnesota [15,16].

Data Collection

The surveys were sent to 180 potential participants on a rolling basis via email. For the trainee physicians, attending physicians, and advanced practice providers, they received 1 email if they had been on service in the prior 2 weeks, and 1 reminder email. For the nurses, the complexity and inconsistency of their schedules required sending the survey to the listserv of all nurses who work in the NICU and limiting responses via branching logic in the survey to only those who had worked in the study period. All nurses received 1 email each week during the study. All participants were asked to complete 1 survey per 2-week period in each study phase. All data were securely stored within Box [17] and REDCap [15,16].

Data Analysis

Quantitative Analysis

Descriptive statistics (counts and percentages) were used to summarize survey questions for the preimplementation and postimplementation periods. Wilcoxon rank sum tests were used to compare the question responses between the periods. *P* values <.05 were considered statistically significant. SAS (version 9.4; SAS Institute) was used for the analysis.

Qualitative Analysis

The open-ended survey responses were analyzed using the rapid template analysis approach [18,19]. Template analysis is a structured approach in which researchers identify major domains covered in a data collection and provide summaries of participant responses for each domain. They then place each summary in a matrix to identify recurring themes under each domain. Coding was done by 2 coauthors (RFR and ESJ). The whole process was iterative until coders came to an agreement. We analyzed 59 and 60 open-ended survey responses, respectively, to each question, "What was most useful about using Q-rounds?" and "What would you suggest changing about Q-rounds to make it more useful?"

Results

Q-rounds was successfully implemented during the crossover period of the study to notify nurses and families of when they were expected for rounds and to allow families to join remotely. The software was used for rounds daily during the intervention period.

XSL•FO
RenderX

A summary of survey respondents by role is provided in Table 1. There were 118 respondents in the preimplementation phase and 110 in the postimplementation phase. Nurses comprised most respondents in both phases: (n=66, 55.9% preimplementation and n=71, 64.5% postimplementation).

Table . Summary of clinical role by survey period.

	Preimplementation (n=118), n (%)	Postimplementation (n=110), n (%)
Attending physician	15 (12.7)	6 (5.5)
Advanced practice provider	24 (20.3)	24 (21.8)
Resident physician	9 (7.6)	5 (4.5)
Fellow physician	4 (3.4)	2 (1.8)
Nurse	66 (55.9)	71 (64.5)
Other	0 (0)	2 (1.8)

The analysis of the quantitative survey data is summarized in Table S1 in Multimedia Appendix 1. The additional questions in our survey, although results not discussed here, are included in Table S2 in Multimedia Appendix 1 for review.

The quantitative findings were supported by our qualitative analysis of the open-ended survey results of physicians, advanced practice providers, and nurses. Of the 110 participants of the postimplementation survey, 66 responded to at least one of the 2 open-ended questions that were thematically analyzed.

The most common coded response regarding usefulness of the software was for improved planning for rounds (n=20, 55%), followed by improved efficiency (n=6, 17%), parent attendance (n=6, 17%), and finally, nurse attendance (n=4, 11%). The most common coded response for suggestions for improvement was for improving the notification system (n=11, 37%), adding additional team members to be notified for rounds (n=10, 33%), improving the timing accuracy of the notifications (n=6, 20%), and lastly, improving education for team members and families regarding Q-rounds (n=3, 10%).

Improved Perceived Attendance by Key Personnel

In the postimplementation period, there was an increase in the perception of nurse presence for the entirety of rounds, with the perception of the nurse being present “most” or “all the time” increasing from 48/105 (46%) to 24/36 (75%; *P*<.001). Similarly, there was an increase in the perception of the family being present for rounds, with clinicians indicating that family was present “at least sometimes” increasing from 45/106 (42%) to 36/36 (97%; *P*<.001). There was no significant difference in time spent waiting for nurses to arrive for FCR (*P*=.47) or the ability to provide daily family updates (*P*=.55). There was no difference in the perception of time waiting for nurses.

The above findings were further supported by the following quotes from the clinicians about their perception of significantly improved attendance:

> *More opportunity for me to be part of family updates, whether listening in and showing/stating agreement with the resident, providing coaching for the resident during family update, or being able to direct/deliver the update.* [Attending physician 115]

> *Simply clicking a button to get the next patient’s nurse and family was so much easier than making calls.* [Attending physician 2]

> *Increased availability for RNs and Parents to join rounds; Improved expectations regarding rounds (i.e.: RN can see an estimated time for rounds and knows when to expect rounds to happen).* [Nurse practitioner 38]

> *Facilitating nurse communication/participation in a timely way.* [Attending physician 23]

While there was an increased perceived opportunity for parents to join, survey participants cited the need for increased family education regarding the software and improvement in the timing of notifications for nurses and families:

> *It was difficult to help families navigate how to add additional parent to Q-rounds.* [Attending MD 2]

> *[We need] better education to parents on how it works to encourage more involvement.* [Nurse practitioner 11]

> *[Would like] allowing for updated time calls when they decide to push rounds back or another patient rounds take really low.* [Nurse 88]

> *[Would be useful to have] calls for updates in expected time changes for rounds if more than 10 minutes different than originally anticipated.* [Nurse 57]

A highly suggested improvement was also to add notifications for other team members:

> *Notifying respiratory therapy would also be useful.* [Fellow MD 1]

> *Include other allied health staff.* [Attending MD 45]

Perceived Enhanced Rounding Efficiency and Planning

There was no change in perceived rounding length (*P*=.40), or the time spent discussing each patient (*P*=.54), which was also supported by the previous observational study [14]. Despite these findings, after implementing Q-rounds, there was an increase in clinicians’ perception of rounding efficiency with the percentage of clinicians who agreed with the statement that rounding was efficient, increasing from 56/105 (53%) to 62/84 (75%; *P*=.006). Similarly, more clinicians indicated they were

XSL•FO
RenderX

satisfied with rounds after implementation of Q-rounds (62/84, 74%) compared to before implementation (59/105, 56%; *P*=.003). Importantly, there was no significant change in satisfaction with trainee teaching time (*P*=.82).

This was supported by a qualitative analysis theme identified highlighting the improved efficiency of the rounding process after the intervention:

> *This decreases the amount of time spent updating families after rounds. It is a huge benefit in regard to workflow and time management.* [Nurse practitioner 71]
>
> *Q-rounds coordinates and calls the nurses and families for us leaving me more time to open charts and notes and prepare. This helps minimize time between patients.* [Nurse practitioner 44]

Furthermore, there was improved perceived ability to have a plan for rounds, including having a rounding order and rough timeline of rounds. Examples of quotes supporting this theme include the following:

> *Knowing a general timeline helped me not be in the thick of a time-consuming treatment/bath/educational moment so I could attend rounds.* [Nurse 86]
>
> *Organization of the rounding structure and personnel, keeping the team on focus.* [Nurse practitioner 36]

Discussion

Principal Findings

This study surveyed clinicians and nurses on their perceptions of rounding practices before and after the implementation of novel rounding software. We found that the respondents had improved perceptions of rounding efficiency and satisfaction with rounding. We also found a perceived improvement in nurse and parent attendance. While there were suggestions for improving the software, they were mainly related to providing education, fine-tuning the notification timing, and including additional team members in the notifications. Both our quantitative analysis and coding of open-ended survey responses supported findings from our previous observational study, which showed that Q-rounds improved nurse and parent attendance [13]. Direct quotes from the clinicians further endorsed the value Q-rounds adds in terms of improving perceived efficiency of rounding practices and overall patient care delivery.

This approach directly addresses barriers to FCRs, such as giving nurses advanced notice of rounding timing and accommodating family schedules, not only by giving advance notice but also by allowing them to join via telephone [8,9]. Our results align with previous studies, showing that schedule-based FCR increases clinician satisfaction [12], and novel nursing contact strategies increase nurse attendance [20]. As with others, we found that families are highly interested in knowing when to expect the medical team for rounds [21], and explicit invitations help to increase caregiver participation [22]. Our intervention is novel, however, in that previous interventions typically focused on approaches at either getting more families or nurses to rounds, but not both [23]. Thus, Q-rounds was broadly regarded as an innovative mechanism for implementing FCR within the NICU, reinforcing prior evidence that FCR enhances the engagement and participation of patients and their families [7]. Our approach is novel in its ability to be seamlessly integrated into the EHR, directly contact parents via technology such as phone app updates, and allow for either in-person or phone family participation. By meeting families where they are, we hope to improve care participation across all socioeconomic backgrounds. We are planning future studies to look more deeply at demographic and social determinants of health factors that may point to this approach, allowing families to participate in FCR who are often unable to attend in the hospital. Future studies will also assess other potential benefits of the increase in multidisciplinary FCR afforded by this approach, including impacts on length of stay and patient satisfaction.

Beyond increasing the presence of key personnel during rounding and making rounds more effective and efficient, the primary goal of FCR is, as the name suggests, to engage families and ensure their presence in the decision-making process. Prior research has demonstrated that when families are more present during rounds and actively involved in shared decision-making, their satisfaction with both the care provided and with the physicians increases [7,8]. Although the referenced study was conducted in an urban midsized city setting, we can see a strong role for virtual or “Q-rounds” in rural environments as well as larger, high-stress, fast-paced cities with commuting delays. Especially in rural settings, various sociodemographic factors such as competing family responsibilities, time limitations, and transportation challenges can make in-person participation difficult. Virtual rounds allow patients and families to engage remotely, ensuring they remain involved in care despite these constraints. Additionally, virtual rounds are valuable in situations where exposure to patients must be minimized, for example, during pandemics, outbreaks of contagious conditions, or when caring for immunocompromised patients. Using a virtual rounding platform reduces infection risk while still maintaining a family-centered approach, regardless of whether the family can be physically present at the bedside.

In a follow-up observational study conducted 2 years after initial implementation, we evaluated whether the early benefits associated with the virtual rounding queue software were sustained over time [24]. We also examined its performance across 2 distinct rounding models: table rounds and walking rounds [24]. When comparing family attendance across the 2 rounding cohorts, overall family presence was similar; however, the walk rounding cohort showed a significantly higher rate of in-person attendance and a greater proportion of nurses present for the entirety of rounds [24]. Rounding duration did not significantly change across any of the table rounding cohorts over time, helping address persistent concerns that FCR reduces efficiency [24]. An important consideration for broader implementation is the feasibility of updating the virtual queue during walk rounds, where the team is physically moving from 1 bedside to the next. Centers that rely heavily on walk-around workflows may require modest adaptations, such as designating a specific team member to update the queue, using hands-free or voice-activated features, or some shortcut functionalities.

XSL•FO
RenderX

There are limitations to this study. This was an initial implementation, limited to rounding teams of the same unit in a single medical center. Future studies will aim to expand to additional units, teams, and medical centers to more fully understand the effect of Q-rounds. While our results found no significant difference in satisfaction regarding time to teach trainees, findings are constrained by the low number of resident physicians who completed the surveys. Further studies focusing on trainees, including medical students, residents, and fellows, are needed to better understand their educational benefits from Q-rounds. Our study did not incorporate family feedback, which will be obtained in a future study. The fact that we were unable to individually target nurses to participate and had to use a large listserv of the entire NICU staff, including those who only work night shifts, prohibited us from being able to calculate a true response rate. We also had a lower response rate (66/110, 60%) for clinicians who answered the open-ended qualitative questions as compared to the quantitative survey questions, which may have limited our thematic analysis. It is worth noting that the clinicians asked to continue to use this approach for rounding in the NICU after the study was complete, and it has since become the standard for rounding across all 4 teams in the 68-bed NICU as well as other units in the same hospital.

At the time of this study, Q-rounds was an internally developed, grant-supported research tool implemented within a single health system, and there were no direct institutional costs associated with its use. Since completion of this pilot, the technology has undergone commercialization and is now available for use at other institutions. Generalizability may therefore be influenced by local resource considerations. For example, at the time of this study, Q-rounds was only able to integrate with Epic's EHR. Institutions seeking to replicate this approach would need to either develop a comparable internal tool or adopt an existing solution, both of which carry financial and operational implications.

Conclusions

Q-rounds provides an innovative approach that addresses multiple previously identified hurdles to FCR, including real-time updated scheduling and the ability to work with families' schedules by creating an option that allows families to confirm attendance by phone or in person. Clinicians perceived having a technical solution that provides real-time updates to nurses and families about the timing of rounds, with the ability for families to join remotely or in person, as an effective way to facilitate multidisciplinary FCR. While previously shown to improve nurses' participation, here we showed that Q-rounds was associated with improved clinician perceptions of efficiency, increased nurse and family participation in rounds, and increased satisfaction with rounds. Future evaluation of Q-rounds integrated into other EHRs and the development of additional features to support multidisciplinary FCR, including virtual family participation by video, enhanced interpreter coordination, and options for families to submit questions in advance of rounds represent potential directions for broader implementation.

Acknowledgments

The authors would like to thank the Q-rounds staff and leadership team, the Fairview Health Services IT staff and leadership team, the neonatal intensive care unit at M Health Fairview Masonic Children's Hospital, Matt Loth, and Bailee Hill for their contributions to the study, as well as all clinicians who participated in this study.

Funding

Abstract

This study assessed families' comfort levels with information-sharing between health care providers and the Special Supplemental Nutrition Program for Women, Infants, and Children (WIC) using a survey-based approach.

(JMIR Pediatr Parent 2026;9:e89731) doi:10.2196/89731

KEYWORDS

WIC; food insecurity; electronic health records; Special Supplemental Nutrition Program for Women, Infants, and Children; data sharing

Introduction

The Special Supplemental Nutrition Program for Women, Infants, and Children (WIC) is an evidence-based federal nutrition program that provides nutrition education, breastfeeding support, health care referrals, and access to healthy foods for low-income families [1]. Studies demonstrate that WIC participation is associated with improved birth outcomes, reduced infant mortality, and better overall child nutrition [2]. Given the benefits of WIC and underenrollment among eligible children, there is increasing interest in strengthening partnerships between health care settings and WIC to facilitate family enrollment and engagement [3].

Although health care systems and WIC care for a shared population, they exist in information silos, utilizing different electronic systems. While states allow sharing of specific data between health care settings and WIC, a form must be completed and faxed, creating barriers. Integrating WIC referrals within clinical care may improve WIC uptake, data sharing, and nutrition/health outcomes, but little research has explored family perspectives about information exchange between health care providers and WIC regarding their child's health [4]. Better understanding family perceptions of information exchange could facilitate improvements in the design of effective, family-centered referral pathways. This study aims to assess families' comfort levels with information-sharing between health care providers and WIC using a survey-based approach.

Methods

Study Design and Intervention

This cross-sectional study was part of a mixed methods study that implemented an innovative electronic health record (EHR)–based WIC screening and referral tool [5,6]. Briefly, WIC staff in three counties were granted secure, online, read-only access to the health system's EHR [7], allowing review of medical charts, sending and receiving secure messages with health care teams, and receiving WIC referrals. This intervention was permissible under a memorandum of understanding that allowed data sharing between the health care system and county health departments. Participants gave verbal permission to have their information shared with WIC, which was documented in the EHR.

Data Collection and Analysis

To understand parent/caregiver perceptions of information-sharing, a telephone-based survey was developed based on a review of the literature [8]. The survey was pilot-tested for face validity with resulting minor changes in sentence structure or word choice. The survey had four sections: (1) WIC participation history, (2) WIC benefit usage, (3) communication between health care team and WIC, and (4) self-reported demographics, including race/ethnicity (Hispanic vs non-Hispanic and Asian, Black, White, or Other [specify]) and food insecurity status using the Hunger Vital Sign [9].

XSL•FO
RenderX

Race/ethnicity were included as variables since WIC participation rates vary by race/ethnicity. Caregivers were eligible to participate if their child was ≤5 years old and attended one of eight participating clinics, received WIC benefits within the past year, underwent WIC EHR screening, and spoke English/Spanish. Eligible participants were purposively sampled via weekly EHR extractions of WIC screening results and were recruited via telephone, consented, and verbally administered the survey by trained research staff (AP, BO-S) in the participant's preferred language. The staff member conducting the survey in Spanish was certified bilingual. Recruitment occurred from March to July 2022. Results were entered into Research Electronic Data Capture. Participants received a US $25 gift card as renumeration.

Results were analyzed using descriptive statistics. Bivariate comparisons between participant groups based upon demographic and other characteristics were made using χ^2 testing or *t* testing (SAS, version 9.4; SAS Institute).

Ethical Considerations

The Wake Forest University School of Medicine Institutional Review Board approved this study (IRB00078127).

Results

Of 100 survey respondents, 93% were mothers. Respondents had a mean age of 29.9 years; 33% were Black, 19% White, and 53% Hispanic; 53% had completed high school (Table 1).

Table . Participant demographics (N=100).

Participant demographics	Values
Caregiver relationship, n (%)	
Mother	93 (93)
Father	4 (4)
Nonrelated caregiver	3 (3)
Caregiver age, mean (SD)	29.9 (6.1)
Caregiver race, n (%)	
White	19 (19)
Black	33 (33)
Other	48 (48)
Caregiver ethnicity, n (%)	
Hispanic	53 (53)
Non-Hispanic	45 (45)
Missing	2 (2)
Child age, mean (SD)	3.5 (0.98)

[a]Other race/ethnicity included: Costa Rican, Hispanic, Mexican, Mayan, multiracial, Puerto Rican, and Salvadorian. These answers were provided via an open-ended text box after "Other" was chosen.

One third (35%) reported food insecurity (FI); 90% reported receiving WIC benefits for ≥1 year (see Multimedia Appendix 1 for full survey results). Overall, 79% were comfortable and 17% were uncomfortable about their child's doctor communicating directly with WIC. Ninety-one percent were very or somewhat comfortable with WIC accessing their child's EHR and 6% were uncomfortable; 95% were very or somewhat comfortable with secure messaging between their child's doctor and WIC. Caregiver race/ethnicity and age were not associated with reported comfort levels (Table 2).

XSL•FO
RenderX

Table . Bivariate comparison between demographics and comfort levels with different activities involving the Special Supplemental Nutrition Program for Women, Infants, and Children's (WIC's) access to electronic health record (EHR) data.

Demographic	Comfortable with doctor communication with WIC[a]	*P* value	Comfortable with WIC staff having access to child's EHR[a]	*P* value	Comfortable with doctors and WIC using the EHR to send secure messages[a]	*P* value
Caregiver race, %						
White	79.0	.84[b]	89.5	.96[b]	89.5	.21[b]
Black	78.8		90.9		100	
Other	83.3		91.7		93.8	
Caregiver ethnicity, %						
Hispanic (n=53)	84.9	.52[b]	92.5	.81[b]	94.3	.39[b]
Non-Hispanic (n=45)	80.0		91.1		97.8	
Comparing mean (SD) age (years) across comfortable versus uncomfortable caregivers						
Comfortable[a] caregivers	29.7 (6.3)	.57[c]	30.0 (6.1)	.60[c]	29.9 (6.2)	.79[c]
Uncomfortable caregivers	30.6 (5.3)		28.9 (6.6)		30.6 (4.0)	

[a]For the "Doctor Communication" question, "comfortable" designation combines individuals with "comfortable" and "neither comfortable nor uncomfortable" survey responses, and for the EHR questions, the "comfortable" designation combines individuals with "very comfortable" and "somewhat comfortable" survey responses in Multimedia Appendix 1.

[b]For comparing rates of "comfortable" responses across categorical groups (eg, race, ethnicity), *P* values are for χ^2 tests.

[c]To compare the mean ages of caregivers who were comfortable versus not for each task, *t* tests were used.

Discussion

While pediatricians, WIC nutritionists, and caregivers alike have identified data security and confidentiality as potential barriers to implementing integrated care models [4], WIC participants in this study were overwhelmingly comfortable with information sharing and integrated communication between health care providers and WIC. These comfort levels did not significantly vary by caregiver age, race, or ethnicity, signifying broad acceptability across demographic groups. Over one-third of caregivers reported FI, and almost all received WIC benefits for a year or longer.

These findings highlight an opportunity—caregivers were largely open to enhanced communication between health care systems and WIC. A prior study showed the majority of health care providers and WIC staff in favor of an EHR-based referral intervention [5]. Given the high prevalence of FI and the favorable attitudes toward EHR-based information sharing, health care systems may be uniquely positioned to bridge service gaps through continued thoughtful collaboration with community-based nutrition programs like WIC. Increasing the uptake of WIC and enhancing communication between the two systems have public health relevance, such as strengthening prevention/early intervention efforts on FI and obesity and reducing inconsistent messaging [10].

Although the American Academy of Pediatrics and the National WIC Association recommend health care referrals to WIC [11,12], practical and policy barriers prevent uptake of this recommendation. Chief among these policy barriers is that, without specialized legal data sharing agreements, bidirectional data sharing between health care systems and WIC is prevented by the Health Insurance Portability and Accountability Act [13]. Modifying such policies to allow for easier bidirectional data sharing could support direct referrals to/from health care practitioners and WIC, improve care coordination, and increase communication between the two entities, which often share populations but are siloed. To support such policies, more research is needed to determine whether WIC accessing the EHR improves efficiency of care and decreases costs and care duplication.

This study had several limitations. While modest, the sample size was limited by funding. Results are from one institution, which may limit generalizability of findings. Social desirability and selection biases may have influenced participant responses; all surveyed caregivers had consented to information sharing/referral, which may have prejudiced their comfort levels with bidirectional communication. Future studies should explore the impact of such information sharing on FI outcomes, parent/caregiver trust, and health care utilization and outcomes over time.

Funding

This project was supported by a grant from Healthy Eating Research, a national program of the Robert Wood Johnson Foundation. This project was also supported by the Wake Forest University School of Medicine Clinical and Translational Science Institute, funded by the National Center for Advancing Translational Sciences (NCATS), National Institutes of Health, through Grant Award Number UM1TR004929. The funding organizations had no role in the design and conduct of the study; collection, management, analysis, and interpretation of the data; preparation, review, or approval of the manuscript; and decision to submit the manuscript for publication.

Data Availability

Deidentified individual participant data (including data dictionaries) will be made available upon reasonable request from the corresponding author. Data are available on request due to privacy/ethical restrictions.

Authors' Contributions

KAS drafted the initial manuscript and critically reviewed and revised the manuscript for important intellectual content.
BO-S and AP collected data and critically reviewed and revised the manuscript for important intellectual content.
KHL conceptualized and designed the study, designed data collection instruments, carried out the initial analysis, and critically reviewed and revised the manuscript for important intellectual content.
KM conceptualized and designed the study, designed data collection instruments, drafted portions of the initial manuscript, and critically reviewed and revised the manuscript for important intellectual content.

Conflicts of Interest

None declared.

Abstract

In this interview study with 24 adolescent-serving clinicians, participants described current online sexual and reproductive health resources they share with adolescents and highlighted areas of improvement to better meet the developmental needs of this age group.

(JMIR Pediatr Parent 2026;9:e89643) doi:10.2196/89643

KEYWORDS

adolescent; sexual and reproductive health; digital literacy; social media; health literacy

Introduction

Adolescents frequently search for and encounter information about sexual and reproductive health (SRH) online [1,2]. While some of this information may be high-quality, patients also access misleading, inaccurate information that can negatively impact health outcomes, with long-term implications [3,4].

Clinicians depend on reliable, accessible online resources to support effective patient education and engagement; however, they may be unfamiliar with peer-recommended websites. The objective of this paper was to identify commonly used online SRH resources, examine expert-identified key considerations for adolescent populations, and assess potential gaps in existing materials to inform the development of improved resources.

Methods

Overview

These findings are part of a broader qualitative study focused on improving clinician-adolescent communication about online information [5]. Self-identified adolescent SRH experts providing clinical care in the United States were recruited through national listserves (Society for Adolescent Health and Medicine, Society of Family Planning) to participate in audio-recorded semistructured interviews over videoconferencing. Clinicians were asked the following questions embedded within a larger interview guide: “Are there any online resources that you provide adolescent patients about SRH? What are resources that you wish you had?”

Transcripts were audited for accuracy, and data were analyzed via the matrix method through rapid qualitative analysis [6] by two team members, with careful review by three additional team members. Participants were provided an opportunity to review and provide feedback on the synthesized findings.

Ethical Considerations

This study was designated exempt by the University of North Carolina at Chapel Hill Institutional Review Board (#24 - 2060). All participants provided informed consent through an electronic survey prior to participation. Data were stored in password-protected files accessible only to the research team. Participants were compensated with a US $50 gift card for their time.

Results

Participant Characteristics

Overall, 24 clinicians participated in our study, representing all US regions. Most were White (n=18, 75%), cisgender women (n=19, 79%), and physicians (n=20, 83%) who were trained in pediatrics (n=17, 71%) and practiced in academic settings (n=20, 83%; Multimedia Appendix 1).

Common Resources

Clinicians described using 10 online sources for high-quality patient-facing information, with various considerations shared for each (Table 1). Many clinicians described being comfortable using 1 to 2 specific resources, and some discussed finding it challenging to keep up with new options. The most recommended patient-facing websites were Bedsider and the Center for Young Women's/Men's Health from Boston Children's Hospital, although several participants cautioned that Bedsider may be most appropriate for older adolescents and young adults.

XSL•FO
RenderX

Table . Clinician-recommended sexual and reproductive health (SRH) information sources with considerations for adolescent populations.

Resource name, description, and social media handle (if applicable)	Reasons to recommend the resource	Limitations or specific patient considerations
Amaze: Provides an overview of developmentally appropriate SRH topics through animated videos (@amazeorg)	• Patient-friendly content that may be especially appropriate for younger adolescents • Corresponding parent content • Available in many languages	• May be less relevant for older adolescent populations
Bedsider: An online resource focused on contraception, abortion, relationships, and health sexuality (@bedsider)	• Patient stories • Interactive tools • Consistent social media presence	• May be more focused on sex positivity versus medical management • Parents may find content inappropriate for younger adolescents
Centers for Disease Control and Prevention: Overview of information about contraception and STIs[a], including options like pre-exposure prophylaxis	• Up-to-date materials across SRH topics • Familiar to most clinicians • Standardized recommendations and guidelines	• Some clinicians concerned about current accuracy and availability of SRH information due to administrative changes
Go Ask Alice: Interactive website with question-and-answer format, offered through Columbia University	• Interactive and provides direct answers to specific questions	• Not described beyond concerns related to the responsibility of clinicians to provide accurate information and being concerned about offline complications after following online advice
Individual clinician social media content creators (eg, @drjenniferlincoln, @drjengunter)	• Allows adolescents to access information on the platforms they already use • Informal education and more engaging content formats • May be targeted to specific demographic or cultural groups	• Hard for clinicians to verify content and may not feel comfortable recommending content that they have not seen • May prefer recommending institutional or organizational social media content
Individual institutional resources: Format varies by institution (eg, websites, brochures/pamphlets, social media accounts)	• May be perceived as more trustworthy depending on patient/family relationship with the institution • Can offer local service recommendations	• May be redundant if other institutions are providing similar resources • More upkeep • Institutional social media often more focused on parents
Planned Parenthood: Provides local clinical services and online educational content (@plannedparenthood)	• Site covers a variety of sexual and reproductive health topics (eg, contraception, STIs) • Can provide local recommendations for how to access care	• Political baggage and may be concerning to parents (ie, assumed connection to abortion)
Reproductive Health Access Project: Online patient-friendly guides for different forms of contraception and abortion care (@reproductiveaccess)	• Nongendered user guides and fact sheets • Based on patient-centered values (ie, not just efficacy)	• Not described
Scarleteen: Sexual education site focused on queer identities (@scarleteenorg)	• Interactivity • LGBTQ+[b] friendly information • Engagement on social media	• Not described
Young Women's and Young Men's Health: Online health resource pages managed by Boston Children's Hospital (@bch_cywh for Young Women's Health)	• High-quality, comprehensive health information across a variety of topics (including beyond SRH) • Available in Spanish	• Gendered name may make site feel less applicable to gender minority youth • Fewer interactive features (ie, more reading)

[a]STI: sexually transmitted infection.

[b]LGBTQ+: lesbian, gay, bisexual, transgender, queer/questioning, plus (others).

Considerations When Sharing Resources

Clinicians stressed the importance of matching resources to the developmental stage of patients, their general literacy skills, and cultural background (Table 2). A few explained that they did not want to overload patients by sharing too many options. Clinicians also discussed the importance of considering the role of parents when administering resources, describing three common scenarios. First, some described providing joint educational resources for adolescents and parents to review together (eg, if a patient was considering contraception to manage heavy menstrual bleeding). Second, some clinicians

XSL•FO
RenderX

provided direct parent-facing resources to help support the child's pubertal development and discussion of common SRH topics. Finally, some clinicians described being cautious in situations where parents may be monitoring adolescents' internet use without their child's knowledge (eg, through search histories), prompting potential concerns about certain content recommended to adolescents (eg, political baggage with Planned Parenthood).

Table . Current and future considerations when recommending sexual and reproductive health (SRH) resources to adolescent patients.

Themes and subthemes	Illustrative quotations
Considerations when recommending online SRH resources	
Developmental stage	• "For things like Bedsider, it was really designed for 21- to 29-year-olds. It's very sex positive, like the Frisky Friday emails and things that are for people who are very comfortable with their sexuality and concepts around sexual health. I think it resonates a lot less with people who are earlier in their journey, or are in cultural communities for which sex positivity isn't the way that this is framed... So I want I want it to be somewhat values-aligned." (Participant 8)
Cultural relevance	• "But there's another [clinician influencer that I recommend] that talks a lot about PCOS and sexual health. And she is actually Muslim. And it's a nice perspective to see that from a Muslim healthcare provider [since I care for] a large Muslim population with my patients." (Participant 15)
Literacy skills and accessibility of information	• "But a lot of my patients don't really like to read, or they don't have good reading skills, or they don't read well in English, and they'd rather watch something. They'd rather listen to something and watch something at the same time, or they prefer to be presented in like a case vignette style of a story or in shorter clips or shorter amounts of information... They can watch, listen, interact, get feedback." (Participant 18) • "We give Bedsider and Young Women's Health to every single person with a uterus that comes in a clinic because they're accessible and have such good information." (Participant 11)
Parental supervision or content directed to parents	• "I hear from patients not uncommonly that they can't look at websites like Planned Parenthood, because if their parents saw a Planned Parenthood in a search engine history or on a web browser, they would freak out because of the historical baggage that comes with the name Planned Parenthood. I don't ever talk about it in [state name]." (Participant 4) • "Amaze, literally at the top, has a whole parent section, and so I think that they acknowledge that parents will be on the website. They expect it, and they're not trying to hide anything. And so that's why I really like that." (Participant 4)
Desired qualities in future online resources	
Adolescent codevelopment and guidance	• "I think that it is important to have adolescents and young adults involved... I think that it's very clear to me that I'm no longer an adolescent, and so like I don't know where the spaces are that this information will be accessed, where [are] the most relevant places people are going and how people are searching. We can hypothesize all we want, but I think that if we really want to create resources and put them in places, the adolescents are on the internet and social media. We need to engage that traffic in those decisions. Maybe I would Google my institution and that's how I would get to the resource, but that might not be how an adolescent is doing it." (Participant 24) • "Yeah, I think something that engaged patients to create it and not healthcare providers. I mean, we could be involved. But we really need patients and young people to explain how to explain this to their peers... So, for example, for the birth control sheets that we came up with like in [state name] we engaged young people, and it turned out talking about menstrual cycles was horrible. They were like, 'What...is a menstrual cycle?' and we were like, 'Oh, it's your period.' And even the word contraception was hard. They were like, 'Can you just say birth control?'" (Participant 4)
Availability in languages other than English	• "I think one of the downfalls of a lot of resources, especially for my patients, is that are that they're not available in languages really other than Spanish and so it doesn't matter if I'm pointing to the best information in the world...[if] they can't access it or read it." (Participant 25)

XSL•FO
RenderX

Themes and subthemes	Illustrative quotations
Established organizations putting content on social media	• "We have a resource sheet and I remember putting it together and being like, 'Would I really use this in clinic?'... When I stopped to think about it from more of a research perspective, I was like, 'I don't think people are going to use this.' And I didn't want it to just be a thing that nobody used. I think that's what made me think about like, maybe Bedsider is a good example. They have an Instagram page, they have a TikTok handle, so why am I giving them the website when they're not going to go to a website?" (Participant 22)
Knowledge about individual creators making high-quality content	• "I know that there are a number of great OB/Gyns, for example, that do a lot of reproductive health. That can be great. I know a lot of institutions now are trying to have representatives send out information in different contexts with a little bit more scientific rigor ideally... I know there are definitely a ton of other providers out there who are making good evidence-based content. But I think the question is can we take part of that, and then combine it with other sources?" (Participant 3) • "I just started doing a dive...on some of the information available on social media related to abortion. And so I haven't yet incorporated giving Instagram accounts or TikTok accounts to patients, but I'm thinking about that, as we did in a deep dive, and what might be coming up for folks, and so wondering if there's room to say, 'Oh, this is an account I suggest you follow, or something like that, and something to consider.'" (Participant 24) • "If I were more of an active social media user and I knew the content creators out there that I think are like really nailing this like I would definitely recommend specific people." (Participant 8)
Engaging, interactive format versus static, text-based resources	• "People really don't like static resources anymore. And this is subjective, but from doing trainings and hearing from people and then dealing with students, something that's like, 'Here's a website that lays out a bunch of text and tells you about stuff,' I don't think it speaks to people anymore. So I think...videos and interactives, and it's real people, and it's not necessarily like an explanation of something, but it's storytelling, I think, is helpful for people. Interactives where people can enter—like decision aids kinds of things, like 'These are the side effects that would bother me,' people are able to interact with and personalize things. That trend toward personalization is very widespread people want things that are tailored to them." (Participant 13)
Patient/family-facing centralized location	• "I think having a more centralized website available. There's bits and pieces of every website that I can pick from knowing what the complaint is, and I can do that as a physician. But I think for patients and parents to be able to go to is the biggest bang. I don't think those are readily available." (Participant 25)

Improvements for Future Resources

Participants expressed a desire for more resources to be available in languages other than English (Table 2). Some described challenges with information on social media being more engaging and accessible than resources created by health care institutions, making it less likely that patients would visit recommended websites than use social media resources. Accordingly, clinicians often wished for specific social media content to recommend, although a few described concerns about this type of resource recommendation since they did not feel that they were able to vet all information from individual creators. Social media accounts from health care institutions were sometimes seen as a good way to combine these goals, although clinicians often described these as currently being aimed at parents as opposed to adolescents.

In general, participants recommended that future resources be created or revised in partnership with adolescents who can help ensure that the resources are developmentally appropriate and engaging, and use patient-friendly language. They also recommended posting these resources in a centralized location that can be updated regularly by experts, which they described would be especially helpful for general pediatricians who may be less familiar with adolescent SRH, as well as for adolescents and parents.

Discussion

Clinicians recommended a variety of online SRH resources to refer adolescents to outside of the clinical encounter. Resources had pros and cons, with certain sources being more appropriate for different developmental stages. Importantly, this study was

XSL•FO
RenderX

not exclusively focused on generating a list of online resources—thus, this may not be an exhaustive list of adolescent-focused SRH online resources—nor does it comprehensively cover all factors that may impact individualized resource provision. Other limitations include a relatively small and homogeneous clinician sample and data collection embedded in a larger study, both of which may reduce the diversity of resources discussed.

Future work is needed for adolescent-engaged content development [7], resources available in languages other than English [8], and integration of high-quality medical content into commonly used platforms (eg, social media) to more effectively reach patient populations who often encounter health information on social networking sites [9]. Additionally, while the Society for Adolescent Health and Medicine currently has a website where many of these resources are compiled, it does not include some of the considerations mentioned by participants (eg, parental concerns) that may impact individualized resource provision [10]. Creating an up-to-date, detailed resource database that is easily accessible to patients, families, and clinicians—potentially supplemented by a list of recommended social media accounts to follow—is one way to help bridge this gap.

These findings can be used to improve identification of developmentally relevant and accurate online SRH content—as well as creation of new resources—that can improve adolescent well-being amid a complex digital information environment.

The Role of Japan's "Hello Baby" Home Visit Program: Secondary Analysis of Municipal Evaluation Data

Abstract

Given growing concern about maternal loneliness in Japan, this secondary analysis of municipal evaluation data suggests that the nationwide Universal Home Visit Program for Families with Infants ("Hello Baby") may serve as an initial point of contact and an entry point for expanding parenting support networks, with most mothers receiving a visit and reporting encouragement to talk with someone afterward.

(JMIR Pediatr Parent 2026;9:e97276) doi:10.2196/97276

KEYWORDS

parenting; loneliness; home visit; social networking; infant; Japan

Introduction

Under Japan's national policy for child health and development, established in February 2021, the proportion of parents who wish to raise their children in their local community is used as a performance indicator. The policy aims to foster communities that collectively nurture and safeguard children's healthy development. Maternal loneliness and isolation are key concerns, and support systems are needed to help mothers build local connections [1,2]. Loneliness scales have been applied to parents raising children [3], and social prescribing has been proposed as a policy response to connect mothers with supportive people and resources in their communities [4]. Universal, early-contact programs that reach almost all families may therefore play an important role.

The home visit program for families with infants, known as the Konnichiwa Akachan (Hello Baby) home visit program, was established under the Child Welfare Act in 2009 and has since been implemented nationwide by municipalities. The program visits households with infants up to 4 months of age to listen to parents' concerns, provide parenting information, assess family needs, and connect families to appropriate services. In Fukushima City, public health nurses and community volunteers each conduct one home visit per infant, and the program is evaluated annually [5]. In this report, we analyze the most recent program evaluation data to examine parents' willingness to share what they learned from Hello Baby home visits with others as a form of proactive networking.

Methods

Study Design

The Hello Baby program evaluation data were obtained from an anonymous survey conducted by Fukushima City in February 2024. The survey targeted households in Fukushima City with children born between April 1 and July 31, 2023. Invitations to participate were mailed to eligible households, and responses were collected through an online system.

Survey Items

The main survey items were whether respondents received a visit from a health care professional (yes/no); whether they received a visit from a community support volunteer (yes/no); the appropriateness of the timing of the visit (too early, too late, or just right); the degree to which they obtained information about the local area (5-point Likert scale); the degree to which the materials provided were useful (5-point Likert scale); whether the visit prompted them to talk with someone about parenting (yes/no); and whom they spoke with (multiple responses permitted). To assess feelings about receiving the visit, respondents were asked to rate their agreement with each of the following 4 statements: "I felt listened to by the visitor," "My anxiety was reduced," "I gained confidence in parenting," and "I would welcome being approached by a community support volunteer in my local area." Likert scale responses ("strongly agree," "agree," "neither agree nor disagree," "disagree," and "strongly disagree") were dichotomized by combining the first two categories as "Agree" and the remaining three categories as "Do not agree."

XSL•FO
RenderX

Statistical Analysis

We first conducted a descriptive analysis of whether the home visit prompted respondents to talk with someone and with whom as our major outcome proxy indicator of proactive networking. Then, we examined the associations between the main outcome indicator and their feelings about receiving the visit by using the χ^2 test. Statistical analyses were conducted using SPSS (version 28), and a *P* value of <.01 was considered statistically significant.

Ethical Considerations

This study involved a secondary analysis of anonymized data, and it did not fall under the Japanese Ethical Guidelines for Medical Research Involving Human Subjects [6]. Ethical review by Fukushima Medical University was therefore not required.

Results

Of the 449 households eligible for the program, responses were obtained from 173 (response rate: 38.5%). A total of 94.2% of respondents received a visit from a health care professional, and 91.9% received a visit from a community support volunteer. Overall, 69.6% of respondents reported that the visit prompted them to talk with someone (Table 1). The most common conversation partners were their husband (68.2%), their mother (38.2%), and their friend(s) (17.9%).

Reporting that the visit prompted them to talk with someone was significantly associated with perceiving the timing of the visit as appropriate, finding the materials provided to be useful, and obtaining information about the local area. Regarding respondents' feelings about the visit, feeling listened to by the visitor, experiencing reduced parenting anxiety, gaining confidence in parenting, and welcoming being approached by a known community support volunteer in the local area were all significantly associated with talking with someone as a result of the visit (Table 2).

Table . Summary of Hello Baby home visit characteristics (N=173).

	Participants, n	Percentage
Visit from a health care professional		
Received	163	94.2
Not received	10	5.8
Visit from a community support volunteer		
Received	159	91.9
Not received (telephone contact only)	14	8.1
Timing of visit		
Too late	1	0.6
Just right	151	87.3
Too early	18	10.6
Did the visit prompt you to talk with someone?		
Yes	119	69.6
No	52	30.4

I would welcome being approached by a community support volunteer in my local area					
Do not agree	5	23.8	16	76.2	<.001
Agree	114	76	36	24	

[a]The χ^2 test was used.

Discussion

Our findings suggest that Japan's Hello Baby home visit program might serve as an opportunity for parents of infants to engage with others in their community. Similar effects of home visiting have been reported in international reviews [7]. Expanding social networks is a core need for mothers, and it is crucial that they realize they do not have to undertake child-rearing entirely on their own [8]. Beginning to talk with others about parenting can be considered a positive sign of recognizing the existing social network. Maternal loneliness is known to be exacerbated by a lack of social support and to increase parenting stress [9]. Even when parents find it difficult to build relationships on their own, face-to-face contact with visitors can help prevent social isolation by facilitating connections with neighbors and the local community. As home visit programs provide opportunities to identify parents' circumstances, including loneliness [10], and link them with social support, their role is likely to become increasingly important [2].

This study has several limitations. First, because existing program evaluation data were used, detailed participant characteristics could not be assessed, and in-depth analyses were not possible. Second, the analysis relied on single-year survey data from one municipality, with a response rate below 40%, which limits generalizability. Respondents might have been somewhat more engaged with the program than nonrespondents, which could have influenced the overall pattern of responses. Further epidemiological studies in Japan are needed to examine the impact of home visit programs on parents' social connectedness [11].

Abstract

This pilot study examined the feasibility and acceptability of implementing a digital in-home air quality monitor among families with children with asthma (N=20). Interview and survey data indicated that the use of this tool was both feasible and acceptable, while highlighting affordability as an important concern for use in future clinical practice for asthma management.

(JMIR Pediatr Parent 2026;9:e92070) doi:10.2196/92070

KEYWORDS

air quality monitor; pediatric asthma; feasibility; acceptability; implementation; digital monitoring

Introduction

Approximately 6 million US children have asthma, and between school and home, they spend 80%-90% of the day indoors [1]. There is evidence that indoor air exposure significantly affects asthma severity. Studies emphasize that the indoor environment and housing quality are crucial determinants of asthma outcomes, yet self-reported assessments are subject to recall bias and misclassification of exposures [2]. The emergence of digital indoor air quality monitors offers a possible scalable and sustainable approach to indoor air data collection that could aid in tailored recommendations for the home environment [3,4]. However, studies utilizing these monitors are still limited in clinical care, and concerns remain about equitable deployment of these tools [3]. The aims of this study are (1) to assess the feasibility and acceptability of using digital in-home air quality monitors in the homes of children with asthma and (2) evaluate the feasibility of providing a WiFi hotspot to overcome internet connectivity barriers.

Methods

Study Design

This was a pilot feasibility study with 20 participants recruited from a pediatric pulmonary clinic from December 2023 to March 2024. Eligibility criteria included (1) children aged 4-17 years old, (2) the *ICD-10* (*International Classification of Diseases, Tenth Revision*) code for persistent asthma in the past 12 months, (3) sleeping in the same room of the same house for 4 or more nights a week (ie, the child's bedroom), and (4) English-speaking caregivers.

The study intervention included an air quality monitor (uHoo Smart Air Monitor) that was placed in the child's bedroom for 3 months, a pre-paid WiFi hotspot (Simple Mobile Moxee Wi-Fi Hotspot), and a summary review with a pediatric allergist at the end of the study. Relative to commercial grade monitors, the uHoo air quality monitor is marketed directly to consumers and may be a more affordable option for some households (US $300). It uses sensors with auto-calibration algorithms to obtain measurements of 8 air quality parameters: carbon monoxide, carbon dioxide, nitrogen dioxide, ozone, particulate matter 2.5, relative humidity, total volatile organic compounds, and

XSL•FO
RenderX

temperature [5]. This device was chosen because of its cost and its acceptable stability and calibration, measured in a laboratory [5]. The WiFi hotspot was paired with the air quality monitor for internet connectivity to upload the data to the uHoo web portal. Participants did not have access to the uHoo app or portal that displayed real-time data and were informed at enrollment that aggregated data would only be reviewed at the completion of the study.

Baseline surveys at enrollment inquired about demographics, home environment, asthma control, digital literacy (ranging from 0-12, with higher scores indicating higher literacy) [6], and asthma self-management (ranging from 0-5, with higher scores indicating higher self-efficacy) [7]. Exit surveys, completed 3 months from enrollment, assessed asthma control, feasibility, acceptability, and usability with the System Usability Scale (SUS) [8]. Feasibility was defined a priori as 1 week of continuous data collection by monitors. Acceptability was assessed through the brief exit semistructured interview and survey. SUS scores range from 1-100, with 70 indicating an "acceptable" level of usability. After the exit survey, a semistructured interview was completed by televideo, and before the interview, the pediatric allergist reviewed the summary air quality findings from the monitor, the child's asthma control scores, and home practices to improve air quality.

Descriptive statistics included frequencies, proportions, and median and IQRs for sample characteristics and survey responses. Interviews were audio-recorded and transcribed, and a deductive approach was used for qualitative analysis (coders: LS, KB, OO, KK) regarding feasibility and acceptability. A convergent mixed methods approach was used to connect interview responses with the survey data.

Ethical Considerations

The Ann & Robert H. Lurie Children's Hospital of Chicago Institutional Review Board (IRB 2023 - 6409) approved this study. The institutional review board determined that this study involves no greater than minimal risk.

Results

The study sample was mostly composed of mothers (n=17, 85%), those living in an apartment/duplex (n=13, 65%), and those with a high school diploma or less (n=12, 60%) (Table 1). Baseline digital health literacy and asthma management self-efficacy were high.

[c]Asthma Control Test (ACT) and Child Asthma Control Test (c-ACT) were combined due to small sample size.

Feasibility

Nineteen of 20 enrolled participants successfully collected continuous indoor air quality data for at least 1 week and averaged 81 (SD 19) out of 90 days. One participant never completed set-up of the device at home. Indoor air data collected an average of 72% (SD 16%) of the available hours for each participant, ranging from 34% to 97%, and 74% of available days had at least 12 hours of data collection. Feasibility measures were rated highly (Table 2 and Multimedia Appendix 1).

Table . Feasibility and acceptability of using a digital indoor air quality monitor.[a]

	Value, n (%)
Feasibility survey questions (n=15)	
How often did the child sleep in the same room as the air quality monitor?	
Everyday	15 (100)
>50% of days in a week (4 or more)	0 (0)
<50% of days in a week (3 or less)	0 (0)
How would you rate the set-up of the air quality monitor (uHoo- the white device) at home?[b]	
Easy/very easy	15 (100)
How would you rate the set-up of the Wi-Fi hotspot at home (the black device?)[b]

Acceptability survey questions (n=15)	
How likely are you to use the air quality monitor in the future if this device was provided to you in clinic?[c]	
Neutral	2 (13)
Very likely/likely	13 (87)
How likely are you to recommend this technology to a family caring for a child with asthma?[c]	
Neutral	2 (13)
Very likely/likely	13 (87)
Would you have joined the study if the WiFi hotspot was not provided?	
Yes	11 (73)
No	1 (7)
Not sure	3 (20)

[a]All participants who completed the exit interview (n=13) had corresponding exit survey data.

[b]Other item responses included very difficult and difficult or neutral.

[c]Other item responses included very unlikely and unlikely.

Acceptability

Fifteen of 20 enrolled participants completed exit surveys and 13 completed exit interviews. Most participants rated acceptability questions highly (Table 2). While most participants reported they would have joined the study if the WiFi hotspot was not provided, only half interviewed (n=7) stated that they would use the monitors if they had to pay for it. Participants described that the “price may be prohibitive” and “insurance probably should cover” it. On the SUS, participants rated the intervention with a median of 67.5 (IQR 56.3 - 81.3).

Discussion

This study demonstrated that data collection with digital indoor air quality was feasible and acceptable to a socioeconomically varied sample of families with children with asthma.

The high feasibility may be due to the pre-pairing of monitors with WiFi hotspots so that participants only had to plug in each device at home with no additional set-up. The air monitor intervention’s usability score, despite scoring similarly to other air pollution monitors (SUS: 50-66), fell slightly below the

XSL•FO
RenderX

threshold for acceptable usability, suggesting further inquiry is needed to understand how usability can be improved. Nevertheless, this rating was similar to how the public rated using cellphones in past evaluations (SUS: 66.5) [8]. Nevertheless, over a quarter of participants were unsure if they would have joined without the WiFi hotspot. Proponents of health equity have highlighted that neighborhood broadband access and perceived digital self-efficacy can limit access and use of digital health tools [9].

For acceptability, most participants reported a future interest in using a digital air monitor if provided by the clinic, and the data reviewed with the pediatric allergist were well-received. This finding fits with those from other digital health studies, that is, that closed-loop communication by the health care team about patient-generated health data is crucial to enhance chronic disease self-management [10]. However, this study's aggregated data report, short enrollment period, and device limitations prohibited more tailored recommendations for improving asthma control.

Despite interest in the monitors, half of the participants also identified that they could not afford the cost of the monitor themselves. A recent Centers for Medicare & Medicaid Services (CMS) policy will address this cost barrier to digital health adoption by reimbursing technology-supported health care, including wearable devices and health coaching apps, for Medicare-insured patients with certain chronic conditions [11]. While this CMS model may alleviate costs for some, this will not address affordability for pediatric populations, and expanded access models for technology-supported pediatric health care should be considered.

Study limitations included (1) participants' lack of real-time air quality data during the study, which affected their ability to make at-home modifications, (2) the inability of this type of air monitor to detect indoor environmental allergens (eg, mold, dander), and (3) the short enrollment period and small sample size, which limited inferences about sustained engagement with the air monitors and impact on asthma control, respectively.

Though the feasibility and acceptability of the digital air quality monitoring intervention were promising in this study, affordability was highlighted by participants as a key barrier to the use of these tools in clinical care. Future studies should also incorporate real-time feedback and associated clinical management with air quality monitoring year-round.

Acknowledgments

We are grateful for the expertise and contributions of the patients with asthma and clinicians from the Lurie Children's Division of Pulmonary and Sleep Medicine.

Generative artificial intelligence was not used in the formation of the manuscript.

Abstract

Background: Adolescents' high engagement with smartphones creates opportunities for mobile health (mHealth) apps targeting dietary behaviors. However, despite the availability of diverse dietary mHealth apps, user engagement remains low. Existing quantitative literature has identified barriers and facilitators to app effectiveness in youth (aged 10-19 years) but has not fully captured the nuanced perceptions of adolescents (aged 12-19 years), who represent a unique life stage. Synthesizing similarities and differences in adolescents' perceptions of what they value in dietary mHealth apps from qualitative studies may provide a more comprehensive understanding of app engagement and future app design.

Objective: We aimed to synthesize adolescents' perceptions of using diverse dietary mHealth apps.

Methods: A scoping review was conducted according to the 5-stage framework by Arksey and O'Malley. Eligible studies were published in English and reported on adolescents (aged 12-19 years) with perceptions of dietary mHealth apps using qualitative methods. Apps that were not specific to diet, relied only on SMS text messaging, were delivered as part of a school-based intervention or telemedicine service, or were housed on a website or social media platform were excluded. Five evidence sources (PsycINFO, Embase, Medline, Web of Science, and CINAHL) were searched. Extracted data were charted by 1 researcher following a pilot test. Similarities and differences in adolescents' perceptions were synthesized across studies using thematic analysis.

Results: Of the 1195 search results, 1.2% (n=14) met the eligibility criteria. We identified six themes that represented adolescents' perceptions of using dietary mHealth apps: (1) functionality and design, (2) content and depth, (3) social connection and support, (4) entertainment and gamification, (5) goal setting and motivation, and (6) perceived effectiveness. Overall, adolescents favorably perceived apps that were easy to navigate, fostered social connections, were personalizable, and were gamified. Apps that were felt to increase awareness of personal eating habits, often through tracking calories and foods consumed, and foster awareness of personal well-being were especially discussed in relation to perceived app effectiveness.

Conclusions: The findings of this review provide an innovative synthesis of adolescents' perceptions of diverse dietary mHealth apps, using qualitative data. Notably, dietary mHealth apps that were perceived as easy to navigate, tailored (eg, in terms of content), and gamified and those that included social engagement were perceived favorably, regardless of their dietary target and features. Apps that were perceived to improve adolescents' current dietary awareness were particularly valued. Inclusion of these elements in dietary mHealth apps may promote greater engagement. App developers should work with adolescents to establish how specific apps can incorporate these elements into their design, including how best to track dietary habits and integrate AI into app features.

XSL•FO
RenderX

Introduction

Adolescence is a critical period marked by rapid physical growth and cognitive development [1,2]. There is broad consensus across disciplines that promoting health-protective behaviors during this life stage, including adequate consumption of fruits and vegetables, can help reduce the risk of chronic disease in adulthood [1,2]. Despite this, evidence from around the world indicates that adolescents' dietary behaviors often do not align with established recommendations [3-5]. For example, the literature from Canada and the United States reports that adolescents tend to consume diets high in sugar, fat, and sodium and frequently skip breakfast [3,4]. These patterns are consistent with findings from Europe and Oceania [6]. In contrast, current dietary guidelines emphasize the importance of consuming fruits and vegetables, whole grains, and protein-rich foods, while limiting foods that have added sodium, sugars, or saturated fats [7,8].

Similar misalignment between dietary recommendations and apparent fruit and vegetable consumption, fast food intake, and sugary carbonated beverage consumption has been observed in Thailand, Suriname, and Nepal [5]. Collectively, this body of evidence highlights that improving adolescents' dietary habits remains an ongoing global public health priority [3-6].

In high-income countries, smartphones may offer a promising avenue to address the gap between adolescents' dietary habits and expert dietary recommendations, given their widespread use within this population, with ownership rates frequently exceeding 90% [9,10]. Dietary interventions delivered through a mobile health (mHealth) platform (eg, apps) have shown significant improvements in dietary habits [11,12]. These interventions may facilitate behavior change by being highly accessible to adolescents [13-15] and often anonymous, thereby reducing barriers such as stigma and cost associated with accessing in-person support [15,16].

General mHealth app use has been associated with significant reductions in sugar-sweetened beverages [11,12,17] and energy-dense snacks [11,12]. Additionally, a systematic review of 14 digital interventions, including 9 targeting dietary outcomes among youth (aged 9-18 years), found improvements in fruit and vegetable intake in 3 studies [17]. However, excessive smartphone use (including use of apps) has also been associated with poorer dietary habits, including reduced fruit and vegetable intake and higher intake of fast food and sugar-sweetened beverages [18]. This dual potential highlights the importance of understanding variations in adolescents' app experiences to identify those most likely to benefit from dietary mHealth interventions [11].

Literature evaluating mHealth app experiences has predominantly focused on identifying barriers and facilitators to app use and effectiveness [11]. A 2023 systematic review of 14 studies outlining youths' (aged 10-19 years) experiences with 13 mHealth apps, 7 of which focused exclusively on diet, identified personalized messages and rewards as key facilitators of effectiveness [11]. Two additional systematic reviews published within the past 5 years, drawing on qualitative studies of youth (aged 4-18 years), reported similar findings, highlighting the value of personalization and rewards, along with simple interfaces, varied content, and inclusion of social support features [19,20].

However, these studies did not distinguish adolescents' perceptions and experiences from those of younger children. This limitation is important, as adolescence is characterized by rapid physical growth and pubertal changes that influence appetite [21] and nutritional needs [22]. It is also a period of identity formation, shifting dietary motivation, and increasing eating outside the home [23,24]. Consequently, findings that aggregate broad age ranges may obscure adolescent-specific experiences with mHealth apps. More recent systematic reviews have not addressed this gap and instead focus on specific outcomes such as sustainable dietary habits (eg, reduction in meat consumption) [25,26]. Consequently, there remains limited understanding of adolescents' perceptions of mHealth apps aimed at general healthy eating.

Poorer app experiences contribute to app disengagement, which may compromise intervention fidelity regardless of app quality [27]. Adolescents who do not fully engage with an app or discontinue use early are likely to be exposed to fewer of its key components and content, limiting its potential to influence dietary behaviors [27]. Given that low engagement is a persistent concern in mHealth research [11,18,28], with many users disengaging within the first month, a more nuanced understanding of adolescents' perceptions of mHealth apps is needed. Such insights could inform app design and improve engagement, thereby enhancing the likelihood of meaningful dietary changes [29]. Existing evidence syntheses have largely focused on barriers and facilitators to app use and effectiveness, often emphasizing the inclusion or exclusion of features [11,19,20] and intervention components [25,26]. However, these approaches may overlook broader experiential factors that shape engagement. This study aimed to build on existing reviews by synthesizing adolescents' perspectives on mHealth app use, identifying both similarities and differences in experiences.

Methods

Overview

We conducted a scoping review following Arksey and O'Malley's [30] methodological framework. Details of our methods and the subsequent results are reported according to the PRISMA-ScR (Preferred Reporting Items for Systematic Reviews and Meta-Analyses Extension for Scoping Reviews) guidelines [31]. The PRISMA-ScR checklist can be found in Checklist 1.

Protocol and Registration

The review protocol was created by the research team and uploaded to the OSF prior to the initiation of the search [32].

Eligibility Criteria

To be eligible for this review, studies had to be published in English and report on adolescents (aged 12-19 years) and their engagement with an mHealth app related to diet and nutrition. This included studies that explored user perceptions of using these apps. We included qualitative and mixed methods studies

XSL•FO
RenderX

that captured perceptions but only analyzed their qualitative data to increase our understanding of the nuances in reported adolescent perceptions that are not typically captured with quantitative data [33]. We excluded studies that reported on adults aged >19 years and children aged <12 years, as they do not experience the same behavioral, social, and biological changes that adolescents face [34]. Furthermore, literature reviews, scoping reviews, systematic reviews, and meta-analyses were not eligible for inclusion. Studies that reported on a school-based intervention, telemedicine services, online platforms, social media, and SMS text messaging systems were excluded to ensure that smartphone apps were the primary focus. Theses, dissertations, conference papers, protocols, and methodology papers were also excluded. There were no restrictions on the year of publication.

Information Sources

In consultation with the research team and 2 trained research librarians, PsycINFO, Embase (Ovid), Medline (Ovid), Web of Science, and CINAHL (EBSCO) were selected as appropriate sources of information.

Search

The search strategy was created in consultation with the university research librarian in 3 stages. First, the search terms were determined using the population, concept, and context framework [35]. Second, the research team identified 3 core papers that had recently been published and were considered critical to answering the research question based on the team's field expertise in dietary behavior change. Finally, with the research librarian, a research assistant developed and tested search syntaxes in all of the identified sources of evidence until all core papers were captured in the searches. The final searches that captured those core papers were considered robust and used. The search strategy and syntax can be found in Table 1.

XSL•FO
RenderX

Table . Search strategy and example of syntax used.

Domains and inclusion	Exclusion	Example syntax[a]
Population		
Adolescents aged 12-19 years	Youth aged <12 years and >19 years	(MH "Adolescence") or (adolescen* or teen* or youth or youths)
Concept		
Perceptions (barriers, facilitators, and experiences)	Telemedicine apps, website-based platforms, SMS text messaging and chat systems, and apps delivered through a social media platform (eg, Facebook) instead of their own unique platform	(MH "Health services accessibility") or (experience* or view* or outlook* or barrier* or facilitator* or challenge* or opportunit* or access* or needs or concern* or perception* or perspectiv*)
Mobile health app	Telemedicine apps, website-based platforms, SMS text messaging and chat systems, and apps delivered through a social media platform (eg, Facebook) instead of their own unique platform	(MH "Mobile Applications") or ((mobile or tele* or virtual or digital or mhealth or m-health or smartphone or cellular) N2 app*)
Dietary behaviors and/or nutrition	Telemedicine apps, website-based platforms, SMS text messaging and chat systems, and apps delivered through a social media platform (eg, Facebook) instead of their own unique platform	(MH "Eating behavior+" or (MH "Diet+" or (MH "Eating") or (diet* or eat or eating or nutrition)
Context		
Apps available to the general adolescent public.	Apps delivered as part of a school-based intervention	No limits applied to avoid prematurely missing an article. Instead, criteria were applied during abstract screening.
Study design		
Report on adolescents' perceptions using qualitative methods	Literature reviews, scoping reviews, systematic reviews, meta-analyses, dissertations, conference papers, protocols, and methodology papers	No limits applied to avoid prematurely missing an article. Instead, criteria were applied during abstract screening.
Language		
English	Non-English	No limits applied to avoid prematurely missing an article. Instead, criteria were applied during abstract screening.

[a]Example syntax shown for the Cumulative Index to Nursing and Allied Health Literature (CINAHL) database. All search syntax components (population and concept) were combined with the Boolean operator AND. Truncation (*), exploding the search to include the main heading and all narrower related terms (+), adjacency operators (N2; within 2 words), and controlled database vocabulary (MH: Medical Heading) were tailored to each respective database. The search syntax included terms related to nutrition apps that were delivered as part of a medical intervention (eg, MH "health services accessibility"). After the search, the research team amended the original inclusion criteria to exclude all nutrition apps delivered as part of a medical intervention (eg, telemedicine) to avoid capturing perceptions that were related to medical support and not the app itself (eg, a clinical care team). The decision was made prior to any abstract screening and applied across all originally returned articles.

Selection of Sources of Evidence

All returned articles from the 5 searched databases were exported into Covidence (Veritas Health Innovation), a web-based reference management software system [36]. Duplicate records were automatically removed by Covidence software. Two research students then independently screened all titles and abstracts for eligible studies. Following this, full texts were reviewed by the same 2 research students. All screening (abstracts and full texts) was done individually, with discrepancies discussed and resolved with the project's senior authors (ASA and TRC).

Data Charting Process

A third research student who was not involved in screening (MBM) completed data extraction independently. MBM used Microsoft Excel (version 2408; Microsoft Corp) to manage the extracted data. Extracted data items were tentatively created prior to the data extraction phase based on previous reviews the research team had conducted. The final list was refined during a pilot extraction using 10% (n=3) of included studies.

Data Items

Extracted data items from the 3 piloted studies encompassed publication information (year, journal, and author names), study

XSL•FO
RenderX

information (location; delivery setting; design; research questions; hypotheses; methods of data collection, analysis, and recruitment; inclusion and exclusion criteria; study length; and stated limitations), participant characteristics (age and/or grade; total sample size; attrition rate; sex and/or gender; prevalence of clinical conditions; and ethnic, racial, and/or cultural background), app details (length of use, app description, stage of development, app name, targeted behaviors, measured outcomes, and app development framework), and app perceptions (barriers, facilitators, attitudes, beliefs, motivators, and suggestions for improvement). After initial extraction, the research team identified the most relevant data items based on the eligible studies. For example, studies did not test the efficacy or effectiveness of a specific dietary intervention; thus, data items such as “length of intervention” were not relevant.

Critical Appraisal of Individual Sources of Evidence

We did not perform a critical appraisal of the included individual sources of evidence, as per the standard protocol of a scoping review [31].

Synthesis of Results

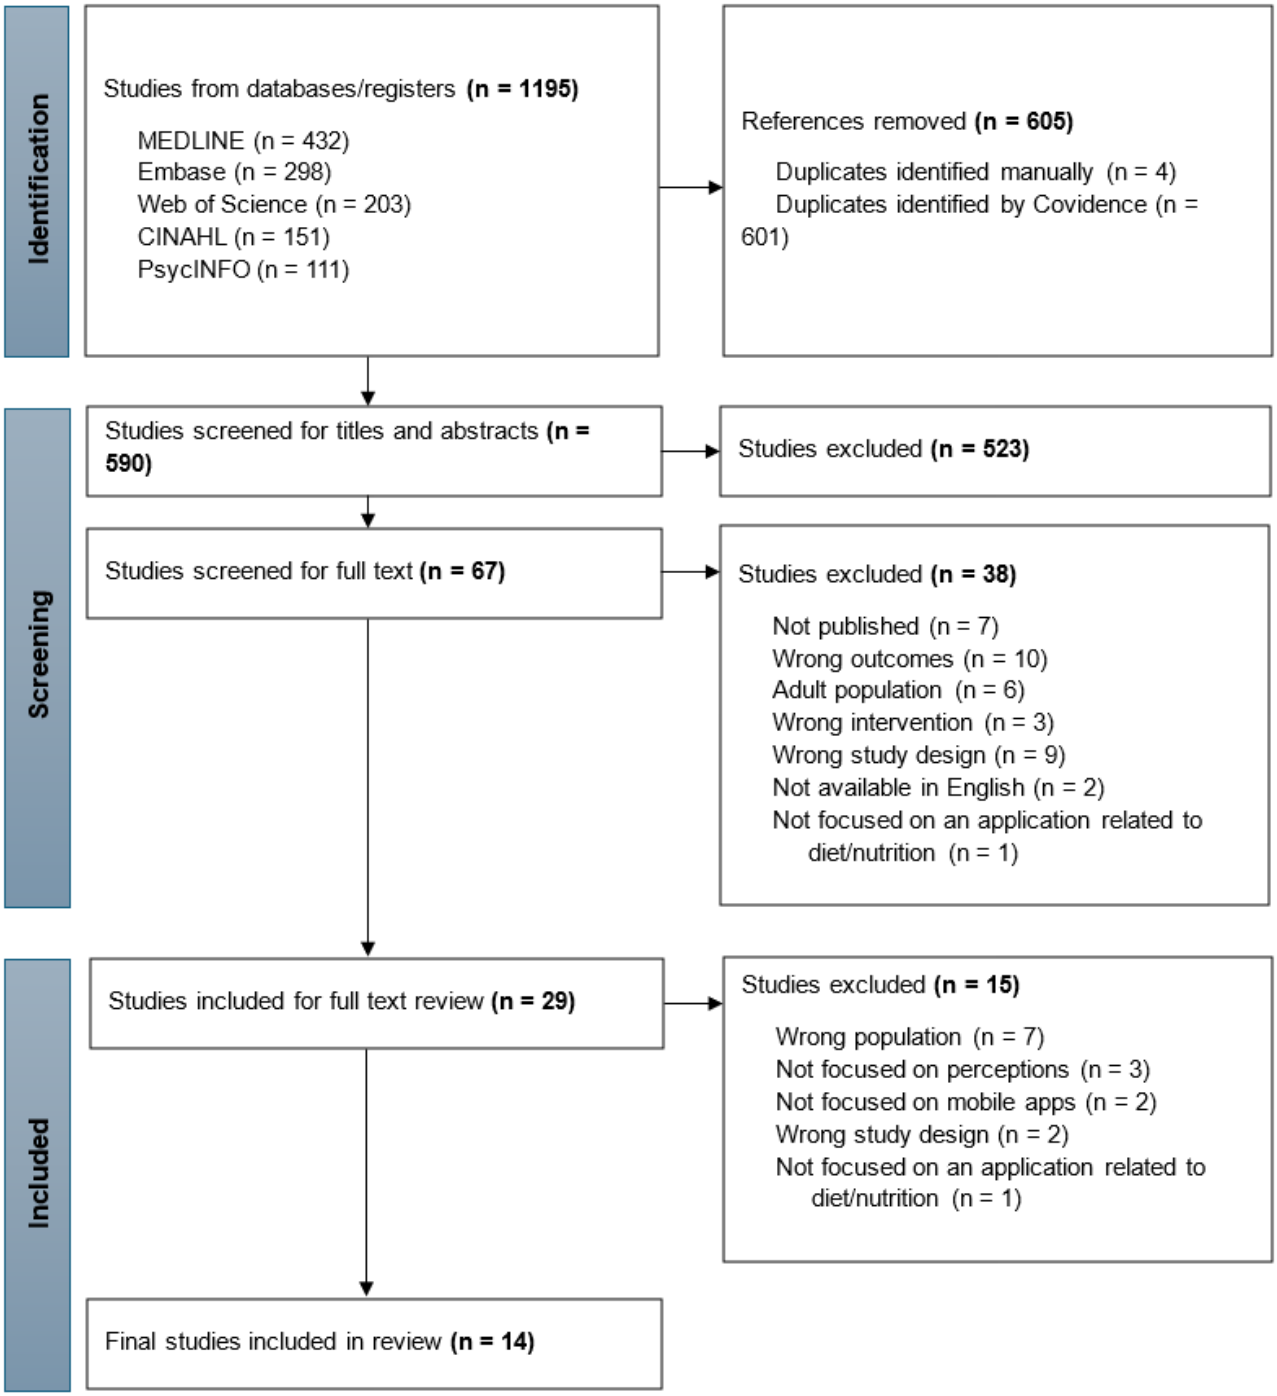
We conducted a thematic analysis [37] to synthesize the extracted data on adolescent perceptions of using dietary mHealth apps. A research student (MBM) first extracted stated app perceptions from the 14 studies using the predetermined categories from the extraction template (eg, barriers). Next, MBM inductively coded similarities and differences in extracted data within a category regarding app perceptions across eligible studies to develop a codebook. Codes were added during the review of each subsequent study. Added codes were then compared with codes from previously reviewed studies in an iterative fashion. Codes were grouped together to inform subthemes based on similarities and differences in underlying meaning. Subthemes were then mapped to inform broader overarching themes. The development of the codebook and the mapping of the themes occurred through discussion among the broader research team (ALD, TCB, and ASA). A summary of all themes and their subthemes is presented in Table 2.

XSL•FO
RenderX

Table . Summary of identified themes and subthemes exploring adolescents' perceptions of dietary mobile health (mHealth) apps.

Themes and subthemes	Sample quotes[a]
Functionality and design (app performance, display, and access)	
Accessibility	"…participants had problems using a type of mobile phone that they were not accustomed to [Android]." [38]
Ease of use	"Participants did not want to spend too long figuring out how to use the app." [39]
Tracking	"Entering information on food consumed was difficult at times." [40]
Visual appeal	"…wanted a brighter color theme." [41]
Concept and depth (quality, depth, and delivery of nutritional information)	
Trusted feedback	"[Adolescents] appreciated getting feedback about their dietary intake in the…app." [38]
Multicomponent	"Features that were suggested by adolescents included information about emotions, mood, and their impact on motivation." [42]
Social connection and support (role of social features in influencing app use)	
Peer connection	"Peers…influenced young people to use apps and device through promoting understandings that they were 'cool,' 'in trend,' and/or 'popular'." [43]
Family interaction	"If you know people who always use it, you can ask them about it, they always recommend apps you should use." [43]
Entertainment and gamification (importance of making apps fun via gamification)	
Tells a story	"They liked the storyline of the game and its mountains climbing theme." [44]
Captures my attention	"I loved this video because of how lively it was! And I accept the mindful eating challenge!" [45]
Rewards	"High levels of enjoyment, especially earning points in the game, were reported." [44]
Goal setting and motivation (emphasis on goal-setting as a way to motivate app use)	
Personalized	"[Participants] liked the idea of being able to set progressive challenges and their own goals." [40]
Hold accountable	"If you accomplished all three goals very well, you'll get a gold badge…If you didn't accomplish any goals, you will not get a badge." [46]
Perceived effectiveness (perceptions of what contribute to app effectiveness)	
Tracking eating habits	"I sometimes did not eat things because then I would have to record them." [38]
Increased knowledge	"Importance of an app that provides them with educational information and manages individualized patient information." [47]
Mind-body connection	"I tried eating my dinner last night mindfully. When I did, I was surprised at how much better my food tasted and how I ate less than [normal]." [45]

[a]Quotes were extracted from the respective article's text or supplemental materials.



Results

Selection of Sources of Evidence

Initially, 1195 studies were identified from the databases. A total of 605 (51%) duplicate studies were removed by Covidence, and 590 (49%) were screened for eligibility. Of the screened studies, 1% (n=14) met the stated criteria. The flow diagram with a complete justification for exclusion can be found in Figure 1.

XSL•FO
RenderX

Figure 1. PRISMA-ScR (Preferred Reporting Items for Systematic Reviews and Meta-Analyses Extension for Scoping Reviews) flowchart.

Characteristics of Sources of Evidence

A summary of extracted study characteristics is provided in Multimedia Appendix 1. Most studies were conducted in high-income countries in North America (4/14, 29%) [39,42,44,45] and Europe (n=6, 43%) [38,40,41,43,48,49], with 4 (29%) conducted outside of these regions, in the Dominican Republic, Indonesia, Korea, and Vietnam [46,47,50,51]. A total of 8 (57%) studies recruited adolescents from schools [38,40,41,43,46,49-51], 4 (29%) from clinical settings (eg, hospitals) [39,42,44,48], and 2 (14%) from community organizations [45,47]. Sample sizes ranged from 5 to 245 adolescents. Participants were between the ages of 12 and 19 years, with female subgroups ranging from 3 to 149 participants and male subgroups ranging from 0 to 106 participants. Only 6 (43%) papers were published before 2020 [38,42,43,45,48,50]. A total of 9 (64%) studies used mixed methods [38,40,41,43-45,48-50], whereas 5 (36%) used qualitative methods only [39,42,46,47,51].

Of the 14 described apps, 6 (43%) focused on diet and nutrition [38,40,41,46,50,51], while 4 (29%) other apps involved additional health behaviors such as physical activity [43-45,49]. Only 2 (14%) studies explored perceptions of adolescents living with a clinical condition (type 1 diabetes) [47,48], and 2 (14%) focused on weight management [39,42]. A total of 6 (43%) apps were in the pilot-testing stage [38,41,45,48-50], 3 (21%) were in development [40,44,46], 3 (21%) were available for download

XSL•FO
RenderX

on the market [39,43,51], and 2 (14%) were described as a concept [42,47].

When it came to the use of behavioral theory to guide development, 1 (7%) study mentioned the use of integrated social cognitive theory, self-determination theory, and narrative transportation theory [44]. One other study used development frameworks such as the integrate, design, assess, and share framework (1/14, 7%) [40].

Critical Appraisal Within Sources of Evidence

We did not perform a critical appraisal within sources of evidence of the included studies, as per the standard protocol of a scoping review [31].

Synthesis of Results

We identified 6 themes to describe adolescents' perceptions of using dietary mHealth apps that are outlined in the following sections. A summary of all identified themes with examples of the text extracted can be found in Table 2.

Theme 1: Functionality and Design

This theme addresses adolescents' experiences with the technical performance and usability of dietary mHealth apps. Four subthemes captured adolescents' perceptions of what hindered and supported their use of dietary mHealth apps (accessibility, ease of use, visual appeal, and tracking).

Adolescents spoke about the important role of creating apps that were accessible regardless of their device and personal context. In particular, this included the need for apps that could be used across software platforms and were accessible on their personal devices, not just those provided by a research team [48]:

> *…downloading [the app] to their own phones, they would continue to use the applications.*

Additionally, adolescents expressed a need for apps that could evolve with their personal content, including having the ability to log diverse foods that they consumed and having access to food lists that were continually updated [51]:

> *…highlighted the importance of updating the list of beverages and drinks, as some kinds of drinks were not included in the database.*

Motivation to use an app was discussed relative to its perceived ease of use and visual appeal. Adolescents spoke about the value of apps that were simple, responsive, readable, and similar to apps they already integrated into their everyday lives [39]:

> *[Participants] used popular apps such as Facebook, Instagram, and Snapchat and specifically reported that they preferred certain weight management apps because it reminded them of those popular app.*

Esthetic components of apps, including design choices about color, font size, and display layout, were also highlighted as important characteristics [51]:

> *I don't think it captures the user's interest much [without images].*

Most apps explored in the 14 studies included some form of dietary tracking (eg, calorie counting). Importantly, adolescents often valued having such features within an app, but recognized nuances associated with these features that influenced having a positive app experience. For some, tracking dietary data led to concerns about privacy, was burdensome, and created confusion when errors appeared [38]:

> *[Participants'] views that the recording of dietary intake was burdensome.*

Theme 2: Content and Depth

This theme reflected adolescents' views on the quality, depth, and delivery of nutritional information and was reflected in 2 subthemes (trusted feedback and multicomponent apps).

Adolescents valued apps that they felt provided accurate and trusted dietary and nutrition information. This included helping with reading food labels [39], understanding their personal nutrition needs, and providing space to receive feedback from experts:

> *[Adolescents] liked taking pictures of barcodes on food items with their telephone so that they could identify the nutritional information regarding foods that they were considering eating.*

In addition to receiving trusted dietary and nutrition advice, adolescents also emphasized how apps that delivered content related to other behaviors, such as physical activity [47] and mental health, were desirable:

> *Participants suggested the possibility of having an exercise section in the app.*

Theme 3: Social Connection and Support

This theme emphasizes the role of social features in influencing adolescents' engagement with dietary mHealth apps. Two subthemes (peer connection and family interaction) were identified.

Adolescents spoke about the value of having spaces within the dietary mHealth apps to communicate with their peers. This was valued as a tool to discuss behavior change strategies, gain encouragement when goals were achieved [42], and socialize irrespective of the topic:

> *Encouragement and coping support were also discussed as potential benefits to a social support feature, which would allow for adolescents to share encouraging messages with peers and to seek out or offer advice.*

Adolescents valued apps that included options to compete or play in-app games with peers [40], and adolescents recognized the added motivational value that could come from having an app and its messaging seem more desirable when their peers also used it:

> *Participants suggested that they could be more engaged with the game if they could interact with other players.*

Family support was also recognized as a way to promote app use through normalization of its use. In contrast to peer-based

XSL•FO
RenderX

support, adolescents spoke about how dietary mHealth app use could contribute to disruption of family routines, depending on what an app asked an adolescent to do [46]:

> *Inconvenience for family members in waiting for the process of taking pictures completely before starting to eat their meals.*

Theme 4: Entertainment and Gamification

This theme captured adolescents' perceptions of the importance of making apps fun via gamification aspects and specifically was broken down into 3 subthemes (tell me a story, capture my attention, and rewards).

Adolescents appreciated apps that used a storyline to deliver relevant dietary information and/or behavior change strategies [40]:

> *Positive about the main idea of the game, mainly because of the novelty of the topic and the setting of the game.*

Use of flashy and attention-grabbing digital content such as videos and images was also desired [49]:

> *Perhaps it would be good to have images? I don't think it captures the user's interest much [without images].*

Finally, the use of rewards helped make engagement fun [40]:

> *Being rewarded with medals that were visible to friends would be seen in a positive way as being motivating to them.*

Theme 5: Goal Setting and Motivation

This theme reflects adolescents' perspectives that goal setting could act as a powerful feature to motivate app use and is separated into 2 subthemes (personalized and hold accountable).

Being able to set and monitor personal dietary goals was expressed positively by adolescents across the studies [46]:

> *Enjoyed seeing daily statistics for individual dietary goals.*

Use of goal setting as a feature to motivate dietary behavior change was also talked about in conjunction with the use of reminders [39] and rewards for completing a goal:

> *Self-monitoring features, such as having reminders, alerts, or notifications to keep them on track with their healthy behavioral goals was a highly preferred feature.*

Theme 6: Perceived Effectiveness

This theme summarizes adolescents' perceptions of specific app components that they attributed to the effectiveness of a dietary mHealth app in altering their behaviors. Specifically, tracking eating habits, increased knowledge, and mind-body awareness were 3 identified subthemes.

Tracking eating habits was favorably viewed as helping adolescents self-monitor their habits and shift their behaviors. This was discussed through the act of recording nutrients and meals consumed, as well as by tracking what was eaten in relation to other aspects of health and well-being outcomes such as monitoring diabetes [47]:

> *The new app could assist them in managing their disease [such as] assistance with carbohydrate counting and food identification, better decisions on food choices using a list of glycemic indexes, and assistance with daily management of the disease.*

Perceptions of increased knowledge, whether related to nutrient needs or to related aspects of health, were further attributed to increased desire to make dietary changes [45]:

> *Better visual understanding of the cornerstones of diabetes self-management: food intake,....*

Finally, observing changes in feelings of well-being [45] further helped adolescents feel that using a dietary mHealth app was valuable:

> *[Adolescents who perceived] the app to be very helpful and enjoyable and reported feeling more relaxed, focused, and peaceful.*

Discussion

Summary of Evidence

This scoping review synthesized evidence on adolescents' perceptions of dietary mHealth apps across 14 studies. Importantly, we focused on adolescents aged 12 to 19 years, in contrast to the broader age ranges of prior reviews that also focused on youth (aged 10-19 years) [11,19,20]. From the evidence synthesis, six themes were identified that captured adolescents' perspectives: (1) functionality and design, (2) content and depth, (3) social connection and support, (4) entertainment and gamification, (5) goal setting and motivation, and (6) perceived effectiveness. Our findings build upon prior reviews that have focused on presenting barriers and facilitators of app features [11,19,20,25,26] to provide a more nuanced perspective that can be used across diverse dietary mHealth apps.

Overall, adolescents value dietary mHealth apps that are simple, fun, and raise awareness of their current habits. Technical ease [19,20], esthetic appeal [19,20], gamification [11,19,20], avenues of social support [20,25], and use of goal setting [19,20,25,26] have all been reported in prior literature as essential facilitators to dietary mHealth app engagement, matching key themes that arose in this scoping review. Importantly, apps that were perceived to be more effective by adolescents specifically included dietary tracking and increased knowledge that moved beyond just nutrition facts, opening up novel avenues for research to consider.

Calorie Counting, Dietary Tracking, and Behavior Change Promotion

Tracking eating habits emerged as a critical subtheme influencing adolescents' perceived dietary changes. This included approaches such as calorie counting and tracking different types of foods consumed. Such dietary self-monitoring is a common feature of many dietary mHealth apps [52]; a 2021 systematic review found that 20 out of 28 included nutrition apps incorporated calorie counters [52]. The review identified

XSL•FO
RenderX

goal setting, personalization, and dietary self-monitoring [52] as key facilitators of app engagement.

Within behavioral medicine, calorie counting is categorized as a behavior change technique (BCT), reflecting dietary self-monitoring [53]. Evidence supports its effectiveness: a meta-regression of 122 diet and physical activity interventions in adults found that self-monitoring accounted for the greatest variability in outcomes, with stronger effects observed when combined with other techniques [54]. These findings align with the present results, suggesting that dietary self-monitoring through strategies such as calorie counting may support behavior change. However, recent literature has raised concerns about calorie counting as a dietary strategy. It can be burdensome, requires a high degree of nutrition literacy [55], and may promote an overemphasis on numerical targets rather than internal cues of hunger and satiety (eg, intuitive eating) [56].

Many countries have adapted national dietary guidelines that use plate-based eating (eg, MyPlate) [56]. These approaches guide intake using proportions of macronutrients (eg, protein) and broader food groups (eg, grains), offering a more visual and intuitive framework for food choices. A Canadian study examining the perspectives of registered dietitians (n=44) and the general public (n=52) found that plate-based approaches were valued for promoting dietary self-awareness through simple visual representations of foods on a plate [55]. Despite this, few mHealth apps have adopted plate-based approaches.

Given that adolescents in this scoping review, as well as prior studies [19,20], report valuing simple and visually engaging app content, plate-based eating may represent a promising dietary self-monitoring strategy in digital content. Beyond simplicity, this approach connects how they feel with what they eat by shifting focus away from numerical targets. This aligns with principles of intuitive eating that emphasize internal cues such as hunger and satiety [56] and are associated with lower odds of poor mental well-being (eg, high depressive symptoms and low self-esteem), body dissatisfaction, and negative weight control behaviors (eg, skipping meals) among adolescents in longitudinal research (n=1491) [57]. Participants in this scoping review also expressed interest in app content linking mental health and dietary behaviors (eg, mind-body awareness subtheme). Taken together, these findings suggest that incorporating plate-based eating into mHealth apps warrants further exploration as a developmentally appropriate and potentially supportive dietary self-monitoring strategy.

Peers and Family Systems as Enactors of Social Support

In this scoping review, social interaction emerged as a key component of valued dietary mHealth apps, consistent with previous reviews [20,25,52]. Importantly, peers and the family unit were identified as particularly important sources of social support. In contrast to prior research, our findings did not highlight a perceived need for the involvement of clinical professionals, suggesting that adolescents may prioritize informal support networks over formal health care input in the context of app use.

A 2023 scoping review of 43 studies evaluating dietary mHealth apps among individuals living with chronic disease (n=256,430; eg, cancer) found that social features connecting users with clinicians or health coaches were key to sustaining behavior change [58]. In contrast, interactions with health professionals were not a central focus for adolescents included in our scoping review. This divergence may reflect differences in health status; adolescents managing complex or chronic conditions may face a greater burden, increasing the perceived value of clinical support.

This interpretation is consistent with findings from studies included in our review, where adolescents valued app content that linked dietary behaviors to disease management (eg, effects on insulin levels in diabetes). As such, these findings suggest that preferences for social support features may vary depending on the health context. Future research is needed to better understand when and for whom different forms of support, such as health coaches or clinical professionals, are most relevant and effective for adolescents using mHealth apps.

In the growing world of AI, it is also important to clarify adolescents' perspectives on AI as a social support feature (eg, a chatbot). A scoping review that explored youths' (aged 10-19 years) acceptability of chatbots in nutrition and physical activity apps found that, in 2 of the 5 reviewed studies, adolescents expressed satisfaction with a chatbot [59]. Interestingly, when the authors discussed the findings on chatbots with a youth advisory panel, youth brought forward additional concerns surrounding the possibility of spreading misinformation through chatbots and data privacy [59]. Although adolescents in our scoping review did not explicitly discuss chatbots, they did highlight privacy concerns with sharing data in an app. This highlights the need to further explore the role of AI within dietary mHealth apps as a source of information or dietary consultant and to understand how adolescents perceive the use of AI within dietary apps as a potential social support feature in greater depth.

Multicomponent Apps

In this scoping review, adolescents expressed an interest in the inclusion of physical activity and mental health support. Previous literature has replicated this finding, with many apps integrating both behaviors alongside each other [11,19,59]. Importantly, our findings highlighted adolescents' perceptions that mental health information and features that foster reflection on emotions and mood were valuable. Although numerous apps exist that target aspects of mental health and well-being [60], such apps are often stand-alone apps that do not encompass dietary aspects or are developed for individuals living with eating disorders [61]. This raises questions as to the extent to which mHealth apps should target more holistic approaches to health as a facet of physical and mental well-being in 1 place, and if such an approach would have benefits for adolescents' behavioral outcomes.

Limitations

Most included studies in this review were conducted in North America and Europe, which limits the generalizability of our findings to diverse cultural contexts and countries where

XSL•FO
RenderX

smartphone use is lower. As recent literature has reported lower smartphone use among adolescents from low- to middle-income countries, especially among female adolescents [62], our findings may not be relevant to all adolescents. We further did not evaluate any objective measures of app efficacy and effectiveness. This means that we are not able to draw conclusions about associations between changes in behaviors and our findings. Furthermore, data charting and synthesis were conducted by a single reviewer, which may have introduced bias in study selection and interpretation. To help mitigate this risk, the research team collaboratively developed the data extraction form and resolved ambiguities through consensus. We also did not have the ability to probe for more specific perceptions of app use across unique devices and contexts. It is possible that the type of device a user owns (eg, Android vs iOS) or context (eg, delivered through a school vs clinical site) may impact adolescents' perceptions of the apps, and these nuances are not captured here. Finally, given the rapid evolution of adolescent smartphone use and mHealth app development, our findings may not reflect the most recent innovations that are on the market today. Future reviews should consider using living methods to allow continual updating of information as it becomes available.

Conclusions

This scoping review provides comprehensive and novel insights into adolescents' perceptions of dietary mHealth apps across a range of dietary mHealth apps—a group whose perceptions have not been explored in depth. Adolescents expressed an interest in apps that are easy to navigate, foster social connections, can be personalized, and have gamified elements. In particular, apps that were perceived to improve awareness of one's dietary habits through tracking and connections to aspects of well-being were desired. Future work is needed to explore how dietary tracking can be best facilitated and the extent to which AI has a role within adolescent-focused dietary mHealth apps.

Acknowledgments

The authors acknowledge Katherine Miller and Prubjot Gill, the two research librarians at the University of British Columbia who assisted in selecting the sources of information and developing the search syntax for this scoping review. The authors also thank Erica McFarland and Hector Silva, who assisted with the preliminary search of the data. Abstract

Background: Medication errors represent a major patient safety concern among hospitalized children due to developmental variability, weight-based dosing, and limited communication capacity. However, the global burden and determinants of pediatric inpatient medication errors remain insufficiently characterized.

Objective: This study aims to estimate the worldwide prevalence of medication errors in hospitalized pediatric patients and to identify factors associated with their occurrence.

Methods: A systematic review and meta-analysis was conducted using Embase, MEDLINE, Web of Science, PubMed, and the Cochrane Library from database inception to June 2025. Observational studies involving pediatric inpatients younger than 18 years were included. The review followed the Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) 2020 statement. Data were pooled using a DerSimonian-Laird random-effects model, with subgroup and sensitivity analyses performed to explore heterogeneity.

Results: A total of 61 studies from 29 countries or regions were included. The pooled prescribing error rate was 28%, the pooled administration error rate was 32%, and 54% of the hospitalized pediatric patients experienced at least one medication error. Prescribing error rates were higher in lower-middle–income countries (44%), intensive care units (34%), antibiotic prescriptions (30%), and studies conducted between 2013 and 2025 (32%). The proportion of patients experiencing medication errors was the highest in upper-middle–income countries (64%), whereas administration error rates were the highest in low-income countries (71%), although these subgroup findings should be interpreted cautiously because of limited numbers of studies and wide CIs. Factors associated with medication errors included intravenous administration (odds ratio [OR] 6.86, 95% CI 3.17 - 14.83), hospital stay longer than 5 days (OR 1.94, 95% CI 1.33 - 2.81), and prescription of 3 or more medications (OR 2.12, 95% CI 1.66 - 2.70).

Conclusions: Medication errors are highly prevalent among hospitalized children worldwide, with substantial variation by region, income level, care setting, and time period. Errors are closely associated with treatment-related factors, underscoring the need for targeted system-level strategies to improve pediatric medication safety.

KEYWORDS

medication errors; pediatric patients; hospitalized children; meta-analysis; prevalence; associated factors; systematic review

Introduction

Medication errors have become a major public health issue threatening patient safety worldwide [1] and are particularly prominent in pediatric health care settings [2]. Children and neonates are reported to be up to 3 times more likely to experience medication errors than adults [3,4]. Due to the limited availability of pediatric-specific formulations, adult medications often require dose calculations, manipulation, or reconstitution to meet individualized pediatric treatment needs [5,6]. In

XSL•FO
RenderX

addition, factors such as complex dose calculations [7], age-related differences in drug metabolism [8], the use of unlicensed or off-label medications [8], and children's limited ability to communicate symptoms and treatment-related concerns [9] may further increase the risk of medication errors. These errors may lead to adverse drug events, prolonged hospitalization, increased health care costs, and even irreversible harm or death [10]. Medication errors impose a substantial burden on health care systems worldwide. In the United States, medication errors are associated with annual costs exceeding US $29 billion, including an estimated additional US $28 million in hospital costs each year [11,12]. In the United Kingdom, medication errors result in economic losses of £9,846,258 annually for the National Health Service and consume a considerable number of bed-days [13]. The World Health Organization has estimated that medication errors cost approximately US $42 billion globally each year [14].

The National Coordinating Council for Medication Error Reporting and Prevention (NCC MERP) [15] defines a medication error as any preventable event that may cause or lead to inappropriate medication use or patient harm while the medication is in the control of a health care professional, patient, or consumer. These events may be related to professional practice, health care products, procedures, or systems and may involve prescribing, order communication, product labeling, packaging, nomenclature, compounding, dispensing, administration, education, monitoring, and use. Medication errors thus span multiple stages of the medication-use process. Prior studies [16] suggest that most medication errors in children occur during the prescription, dispensing, and administration stages. Among them, prescription errors account for 3% to 37% of children's medication errors, dispensing errors account for 5% to 58%, and administration errors account for 72% to 75% of children's medication errors [17].

Although numerous studies in recent years have examined the epidemiology of pediatric medication errors [18-20], substantial methodological heterogeneity persists. Inconsistencies in the operational definitions of medication errors, variation in data collection methods, diversity of study settings, and differences in denominators have resulted in wide variability in reported prevalence, limiting comparability across studies. Gates et al [21] stratified pooled estimates of medication error prevalence in hospitalized children by ward type and use of health information technology, but their work focused solely on quantitative synthesis of prevalence without systematically addressing associated factors. This lack of root cause analysis limits the ability to develop efficient and targeted prevention strategies in clinical practice.

To address these gaps, we conducted a systematic review and meta-analysis with two primary objectives: (1) to evaluate the occurrence of medication errors among hospitalized pediatric patients worldwide and (2) to identify factors associated with medication errors in hospitalized children. By consolidating epidemiological evidence, our study aims to support the development of more precise and evidence-based strategies for the prevention of pediatric inpatient medication errors.

Methods

Search Strategy and Study Selection

The systematic review and meta-analysis was conducted and reported in accordance with the Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) 2020 statement (Checklist 1). A comprehensive search was conducted in Embase, Web of Science, the Cochrane Library, MEDLINE, and PubMed from database inception to June 2025. A combination of MeSH terms and free-text terms was used, including "children," "hospitalized," and "medication errors." Detailed search strategies for each database are provided in Multimedia Appendix 1. This study was registered with PROSPERO (registration number: CRD42024613159).

Inclusion criteria were (1) hospitalized pediatric patients aged less than 18 years, including those in general pediatric wards, pediatric intensive care units (PICUs), and neonatal intensive care units (NICUs); (2) studies reporting the prevalence of medication errors or investigating associated factors; and (3) observational studies (cross-sectional, cohort, or case-control).

Exclusion criteria were (1) studies focusing exclusively on specific patient populations (eg, oncology patients) or specific drug categories; (2) studies based solely on voluntary reporting systems, as these systems rely on active reporting by health care professionals and may underestimate the true prevalence of medication errors; however, studies that combined voluntary reporting with active surveillance methods, such as direct observation, medical record review, or other systematic detection approaches, were included; (3) non-English publications; and (4) conference abstracts, posters, studies with insufficient data, or studies for which the full text was unavailable.

Data Extraction and Quality Assessment

Two investigators independently extracted data using Microsoft Excel, including first author, publication year, country or region, study design, ward type, study period, age range or mean age (SD) of included children, data collection methods, source of medication error definition, prevalence of medication errors (%), and associated factors. Discrepancies were resolved by a third investigator. For overlapping datasets, the study with the larger sample size was prioritized.

Cohort and case-control studies were assessed using the Newcastle-Ottawa Scale (NOS), with scores of 0 to 3, 4 to 6, and 7 to 9 indicating low, moderate, and high quality, respectively [22]. Cross-sectional studies were evaluated using the Agency for Healthcare Research and Quality (AHRQ) criteria, with scores of 0 to 3, 4 to 7, and 8 to 11 indicating low, moderate, and high quality, respectively [23]. Studies of all quality levels were included to capture all available evidence in the field.

Outcome Definitions

This study initially planned to extract data on various types of medication errors, including prescribing errors, dispensing errors, and administration errors. However, because some error types were reported in only a limited number of studies and exhibited substantial variability in reporting methods,

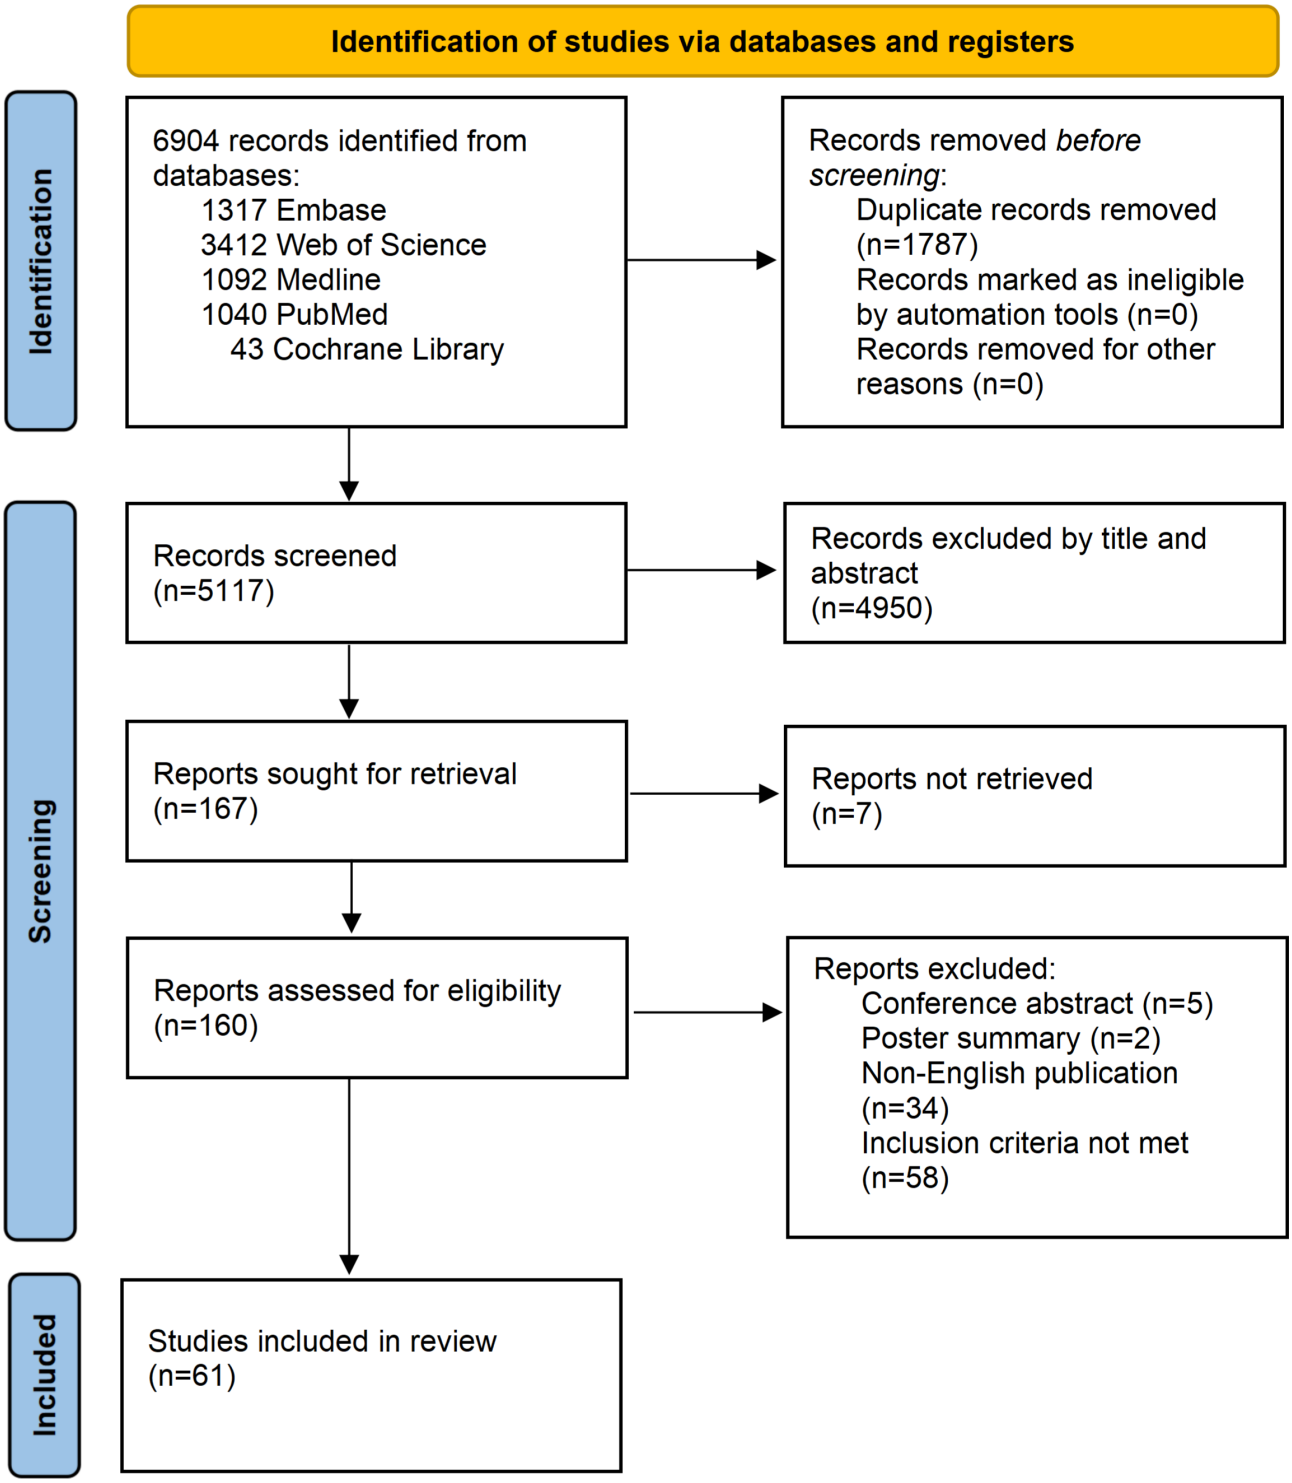
XSL•FO
RenderX

meta-analyses were conducted only for outcomes that met the criteria for quantitative synthesis, namely the proportion of patients experiencing medication errors, prescribing error rates, and administration error rates.

To avoid misinterpretation arising from differences in units of analysis, the outcome measures were defined as follows. The prescribing error rate was defined as the proportion of prescriptions containing at least one medication error among all prescriptions, reflecting the occurrence of medication errors during the prescribing process. The administration error rate was defined as the proportion of medication administrations involving at least 1 medication error among all medication administrations, reflecting the occurrence of medication errors during the medication administration process. The proportion of patients experiencing medication errors was defined as the proportion of patients who experienced at least one medication error during the observation period among all patients, reflecting the overall burden of medication errors among hospitalized pediatric patients. Because these outcomes were calculated using different units of analysis (prescriptions, medication administrations, and patients), their estimates represent different aspects of medication error occurrence and should not be directly compared.

Statistical Analysis

All statistical analyses were performed using Stata (version 17.0). Neither the Freeman-Tukey double arcsine transformation nor the logit transformation was applied to the original proportions. For the meta-analysis of medication error occurrence among hospitalized pediatric patients, the effect size was the medication error rate. For the meta-analysis of factors associated with medication errors, the effect size was expressed as the odds ratio (OR) with its corresponding 95% CI. Given the substantial heterogeneity among the included studies (I^2> 50% and P<.05), pooled estimates were calculated using the DerSimonian-Laird random-effects model. Subgroup analyses were conducted according to relevant study characteristics and associated factors to explore potential sources of heterogeneity. To assess the robustness of the findings, several sensitivity analyses were performed. A leave-one-out analysis was conducted to evaluate the influence of individual studies on the pooled estimates. In addition, restricted maximum likelihood (REML) estimation was applied within the random-effects framework to examine the impact of different τ^2 estimation methods on the pooled results. Publication bias was assessed using both Egger's test and visual inspection of funnel plot symmetry. All statistical tests were 2-sided, and P<.05 was considered statistically significant.



Results

Literature Search

A total of 6904 records were identified through searches of Embase, Web of Science, the Cochrane Library, MEDLINE, and PubMed. After removing 1787 duplicates, 4950 records were excluded based on titles and abstracts, and 7 reports were excluded because the full text was not available. Following full-text review, 99 articles were further excluded for not meeting the inclusion criteria, leaving 61 studies for analysis. The study selection process is summarized in Figure 1.

Figure 1. Flow diagram of the study selection process.

Characteristics and Quality Assessment of the Included Studies

Details of the included studies are provided in Table 1, with sample sizes ranging from 20 to 8691 participants. The studies were conducted across 29 countries or regions, including 14 high-income, 8 upper-middle–income, 4 lower-middle–income, and 3 low-income countries. Ward types included general pediatric wards, PICUs, and NICUs. Among the included studies, 35 were cross-sectional, with AHRQ scores ranging from 4 to 7 (Table S1 in Multimedia Appendix 2), and 26 were cohort studies, with NOS scores ranging from 3 to 9 (Table S2 in Multimedia Appendix 2). To ensure that all available data were used to estimate medication error rates, no studies were excluded based on methodological quality; all original studies reporting medication errors were included.

The types of medication errors reported in the included studies included prescribing errors, administration errors, dispensing errors, and medication reconstitution errors. However, because only a limited number of studies reported on dispensing errors and medication reconstitution errors, and substantial variability existed in outcome definitions and reporting methods, reliable

XSL•FO
RenderX

quantitative synthesis was not feasible for these error types. Therefore, meta-analyses were conducted only for the proportion of patients experiencing medication errors, prescribing error rates, and administration error rates among hospitalized pediatric patients.

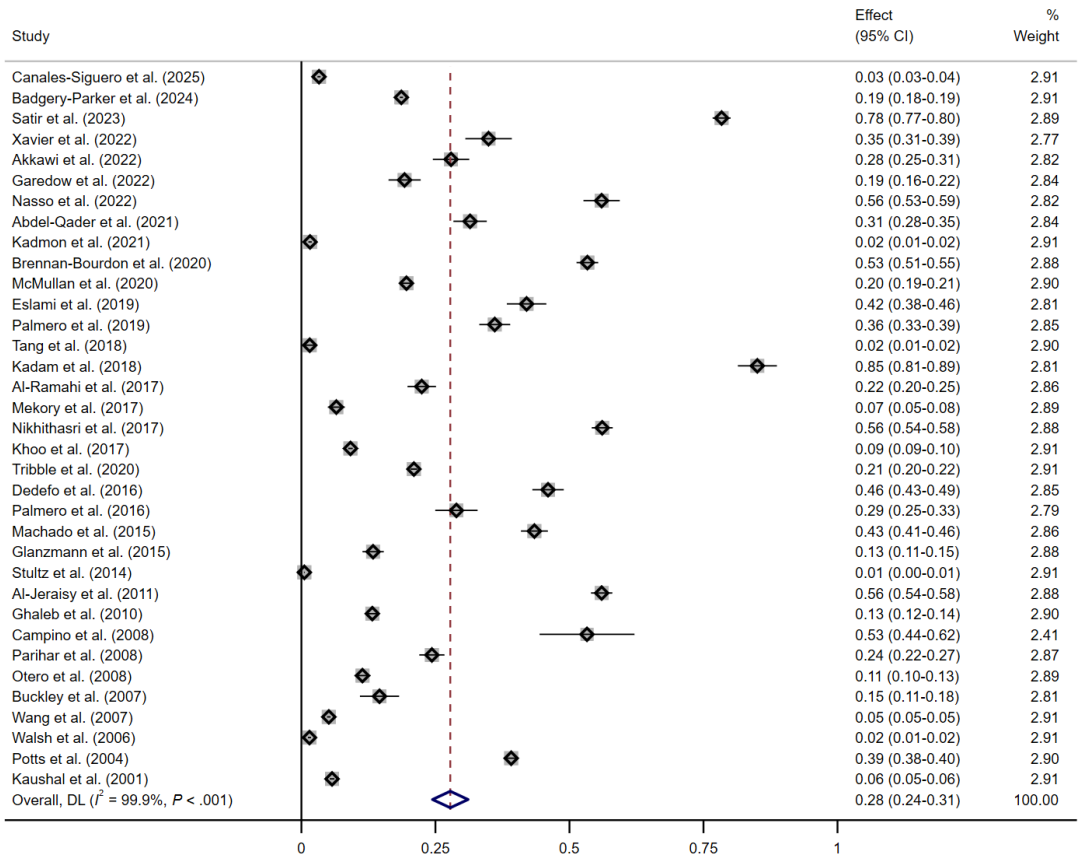
[i]NICE: National Institute for Health and Care Excellence.

[j]PICU: pediatric intensive care unit.

[k]PEC: pediatric emergency care.



[l]ASHP: American Society of Health-System Pharmacists.

Meta-Analysis of Prescribing Errors in Hospitalized Pediatric Patients

Based on the denominators used in the included studies, we reported prescribing and administration error rates as well as the proportion of patients experiencing medication errors. Thirty-five studies [3,24,26,30,32-35,38,39,42,44,47,49-51,56-59,61-66,70,74,76-81,83] reported prescribing error rates in hospitalized children. Significant heterogeneity was observed among studies (I^2=99%; P<.001). Sensitivity analyses using a leave-one-out approach indicated that no single study significantly influenced the overall results. Therefore, a random-effects model was applied. The pooled prescribing error rate among hospitalized pediatric patients was 28% (95% CI 24% - 31%; Figure 2).

XSL•FO
RenderX

Figure 2. Forest plot of prescribing error rates in hospitalized pediatric patients. Weights are from random effects model. DL: DerSimonian-Laird [3,24,26,30,32-35,38,39,42,44,47,49-51,56-59,61-66,70,74,76-81,83].

Subgroup Analysis of Prescribing Error Rates in Hospitalized Pediatric Patients

Subgroup analyses of prescribing error rates are presented in Table 2, with the number of included studies reported for each category. When stratified by study design, prescribing error rates were comparable between cohort studies (28%, 95% CI 23% - 34%) and cross-sectional studies (27%, 95% CI 22% - 32%). By country income level, prescribing error rates appeared higher in lower-middle–income countries (44%, 95% CI 24% - 64%) compared with low-income countries (33%, 95% CI 16% - 51%), although the number of studies in each subgroup was limited and CIs were wide. Regional subgroup analysis showed variability across geographic areas. The highest estimate was observed in Latin America and the Caribbean (36%, 95% CI 8% - 64%), whereas North America showed a lower estimate (12%, 95% CI 7% - 17%). However, these differences should be interpreted cautiously due to limited study numbers and substantial uncertainty. Regarding ward type, intensive care units showed higher prescribing error rates (34%, 95% CI 29% - 39%). For prescription types, antibiotic medications showed slightly higher error rates (30%, 95% CI 24% - 36%) compared with nonantibiotic medications (27%, 95% CI 24% - 31%). For temporal trends, studies conducted between 2013 and 2025 showed higher prescribing error rates (32%, 95% CI 26% - 38%) compared with those conducted between 2000 and 2012 (18%, 95% CI 14% - 22%). However, this finding should be interpreted cautiously given potential differences in study settings, definitions, and data collection methods across time periods.

Meta-Analysis of the Proportion of Patients Experiencing Medication Errors

Based on the denominators used in the included studies, we reported the proportion of patients experiencing medication errors, as well as prescribing and administration error rates. Eighteen studies [25,28,29,31-33,36,37,40,41,47,48,52,55,56,61-63] reported the proportion of patients with medication errors. The meta-analysis showed significant heterogeneity across studies (I^2=99%; P<.001). A sensitivity analysis using the leave-one-out method indicated that no single study had a substantial impact on the pooled results. Therefore, a random-effects model was applied. The analysis estimated that 54% of the hospitalized pediatric patients experienced at least 1 medication error (95% CI 42% - 67%), as shown in Figure 3.

Figure 3. Forest plot of the proportion of hospitalized pediatric patients experiencing medication errors. Weights are from random effects model. DL: DerSimonian-Laird [25,28,29,31-33,36,37,40,41,47-49,52,55,56,61,62].

Subgroup Analysis of the Proportion of Patients Experiencing Medication Errors

The results of the subgroup analysis are presented in Table 3, with the number of studies reported for each subgroup. By study design, similar proportions were observed in cohort studies (57%, 95% CI 24% - 90%) and cross-sectional studies (54%, 95% CI 41% - 67%). By national income level, upper-middle–income countries showed a higher proportion (64%, 95% CI 50% - 77%) than other groups, but the number of studies was small. By region, estimates varied from 26% (95% CI 25% - 26%) to 85% (95% CI 78% - 90%). These results should be interpreted with caution due to limited studies and wide CIs. By prescription type, nonantibiotic prescriptions showed a higher proportion (66%, 95% CI 53% - 79%). By time period, the estimates were similar between 2018 and 2025 (55%, 95% CI 37% - 72%) and 2000 - 2017 (52%, 95% CI 34% - 69%).

Meta-Analysis of Medication Administration Errors in Hospitalized Pediatric Patients

Fifteen studies [25-27,43,45,46,50,53,54,57,68,72-74,82] reported medication administration error rates in hospitalized pediatric patients. Meta-analysis revealed substantial heterogeneity among studies (I^2=99%; P<.001). Sensitivity analysis using the leave-one-out method indicated that no single study significantly influenced the overall estimate. Therefore, a random-effects model was applied, showing that the pooled rate of medication administration errors was 32% (95% CI 21% - 44%; Figure 4).

XSL•FO

Figure 4. Forest plot of medication administration error rates in hospitalized pediatric patients. Weights are from random effects model. DL: DerSimonian-Laird [25-27,43,45,46,50,53,54,57,68,72-74,82].

Subgroup Analysis of Medication Administration Error Rates in Hospitalized Pediatric Patients

The results of the subgroup analysis for administration error rates are presented in Table 4, with the number of studies reported for each subgroup. By study design, cohort studies showed higher estimates (39%, 95% CI 15% - 62%) than cross-sectional studies (29%, 95% CI 16% - 42%). By national income level, low-income countries showed a higher estimate (71%, 95% CI 69% - 73%) compared with other groups, but the number of studies was limited. By region, estimates varied across areas, ranging from 3% (95% CI 3% - 3%) to 71% (95% CI 69% - 73%). These differences should be interpreted cautiously due to limited data and uncertainty. By ward type, ICU (33%, 95% CI 10% - 57%) and general wards (33%, 95% CI 18% - 48%) showed similar estimates. By study period, estimates were 40% (95% CI 20% - 60%) and 29% (95% CI 11% - 47%), with overlapping CIs.

Meta-Analysis of Factors Associated With Medication Errors in Hospitalized Pediatric Patients

Intravenous administration, hospital stay longer than 5 days, and prescription of 3 or more medications were identified as factors associated with medication errors in hospitalized pediatric patients. Among these, intravenous administration was most strongly associated with medication errors (OR 6.86, 95% CI 3.17 - 14.83), followed by the prescription of 3 or more medications (OR 2.12, 95% CI 1.66 - 2.70) and a hospital stay longer than 5 days (OR 1.94, 95% CI 1.33 - 2.81; Table 5).

XSL•FO
RenderX

Table . Meta-analysis of factors associated with medication errors in hospitalized pediatric patients.

Associated factors	Number of studies	Minimum OR[a]	Maximum OR	Pooled OR (95% CI)	I^2 (%)	*P* value for heterogeneity
Route of administration (intravenous vs oral)	4	3.36	21.18	6.86 (3.17-14.83）	89.4	<.001
Sex (male vs female)	3	0.82	1.09	1.00 (0.80-1.26）	0.0	.61
Hospital stay (>5 days vs <5 days)	5	1.34	3.46	1.94 (1.33-2.81）	63.1	.03
Number of prescribed medications (≥3 vs 1 - 2)	5	1.24	7.02	2.12 (1.66-2.70）	40.1	.15
Weight (>20 kg vs <10 kg)	2	1.13	1.7	1.28 (0.63-2.58)	0.0	.60
Night shift	2	0.81	3.06	1.52 (0.41-5.60)	94.9	<.001

[a]OR: odds ratio.

Sensitivity Analysis

Sensitivity analyses were conducted using a leave-one-out approach. Sequential exclusion of each study did not materially change the pooled estimates for prescribing errors, proportion of patients experiencing medication errors, or administration errors, indicating the robustness of the findings (Figures S1-S3 in Multimedia Appendix 3). To assess the robustness of the pooled estimates, the results obtained using the DerSimonian-Laird method were further validated using the REML method. The pooled effect estimates derived from the 2 methods were highly consistent, with substantial overlap in the corresponding 95% CIs, indicating good robustness of the study findings (Figures S4-S6 in Multimedia Appendix 3).

Publication Bias

Because fewer than 10 studies were included for each factor associated with medication errors, publication bias was only assessed for medication error rates. Multiple methods were used to evaluate publication bias. Funnel plots for prescribing errors, administration errors, and proportion of patients with medication errors showed asymmetry (Figures 7-9 in Multimedia Appendix 3). Egger tests indicated potential publication bias for prescribing errors and administration errors (z=9.39; P<.001 and z=2.25; P=.03). However, nonparametric trim-and-fill analyses (imputed studies=0) suggested that no additional studies were needed. Therefore, the observed asymmetry likely reflects true heterogeneity between studies rather than solely publication bias.

Discussion

Principal Findings

This systematic review and meta-analysis evaluated the overall medication error rates and associated factors in hospitalized pediatric patients. We found that 54% of the pediatric inpatients experienced a medication error, which is lower than the 69.5% reported by Bante et al [31]. The pooled prescribing error rate was 28%, comparable to the 28.9% reported by Palmero et al [63] but higher than the 17.5% reported by Koumpagioti et al [84]. The administration error rate was 32%, slightly lower than the 37% reported by Westbrook et al [27]. These discrepancies may be attributable to differences in the characteristics of the included populations, definitions of medication errors, and data collection methods. Furthermore, intravenous administration, hospital stay longer than 5 days, and prescription of 3 or more medications were identified as factors associated with medication errors, providing clinically relevant insights for error prevention strategies.

This systematic review and meta-analysis evaluated prescribing error rates, the proportion of patients experiencing medication errors, administration error rates, and associated factors among hospitalized pediatric patients. Notably, substantial heterogeneity was observed across all primary outcomes, and therefore the pooled estimates should be interpreted with caution. The observed heterogeneity may be attributable to methodological and clinical differences among the included studies [85]. Specifically, studies varied in their units of analysis, with some reporting errors per patient and others per prescription or medication administration. Variations were also identified in medication error detection methods, including direct observation, medical record review, and database-based data extraction, which may differ in their ability to identify errors. Furthermore, the included studies were conducted across diverse clinical settings, such as general pediatric wards, NICUs, and PICUs, where patient characteristics, medication-use processes, and risk profiles may differ substantially. In addition, definitions of medication errors were not uniform across studies. Collectively, these factors may have contributed to the high level of heterogeneity and may limit the generalizability of the pooled findings [86]. Therefore, the results of this review should be interpreted as reflecting the overall trends across the included studies rather than precise estimates applicable to all pediatric inpatient settings.

Subgroup analyses across prescription, patient, and administration dimensions highlight the complexity and heterogeneity of pediatric medication errors. Geographic and economic differences were observed, with higher estimates reported in Latin America and the Caribbean, Africa, and low-

XSL•FO
RenderX

to middle-income countries. These findings may reflect differences in health care resources, reporting practices, and system development; however, they should be interpreted cautiously given the limited number of studies in several subgroups and substantial heterogeneity. Lower estimates observed in North America may be associated with more developed medication safety systems; however, this explanation remains speculative and was not directly examined in the included studies. Temporal trends showed higher prescribing error rates and a higher proportion of patients experiencing medication errors in more recent studies, which may reflect improved detection and reporting practices over time. In contrast, administration error rates appeared to decrease in recent years. PICUs consistently showed higher error rates, likely reflecting the complexity and high-risk nature of these clinical settings [87,88].

The findings of this study suggest that medication errors in hospitalized pediatric patients are closely associated with treatment-related factors, including intravenous administration, hospital stay longer than 5 days, and the prescription of 3 or more medications. However, as this study is based on observational data, the results reflect statistical associations rather than causal relationships, and residual confounding cannot be excluded.

Intravenous administration was associated with a higher likelihood of medication errors compared with oral administration (OR 6.86). This finding suggests that intravenous delivery may be an important factor associated with medication errors. Similar results have been reported by Westbrook et al [27], who observed 5137 medication administration events in hospitalized children and found that intravenous medications were associated with higher error rates, reaching 77.4% for injections and 64.7% for infusions. The complexity of intravenous medication processes, including dose calculation, dilution, preparation, and infusion rate adjustment, may contribute to the increased risk of errors. Pediatric dosing, which is often based on body weight or body surface area [62], further increases complexity. Rajakumar et al [89] also reported that such individualized dosing increases the risk of medication errors. In addition, pediatric doses are often substantially lower than adult doses, and even minor calculation or measurement errors may result in clinically significant dosing deviations, potentially leading to serious harm [74].

Patients with a hospital stay longer than 5 days were more likely to experience medication errors compared with those with a stay of 5 days or less (OR 1.94). This finding is consistent with the study by Bante et al [31], which also reported that longer hospital stays were associated with a higher risk of medication errors. Longer hospitalization may be associated with increased exposure to medications, resulting in a greater number of prescribing and administration processes, which in turn increases the opportunity for errors. However, any assumption that prolonged hospitalization directly leads to reduced adherence to verification procedures should be interpreted with caution, as this was not directly examined in the included studies.

Children receiving 3 or more prescribed medications had a higher likelihood of medication errors compared with those receiving fewer than 3 medications (OR 2.12). However, evidence regarding the underlying mechanisms of this association remains limited. This finding may be related to increased complexity in medication management as the number of prescriptions increases, including prescribing, verification, dispensing, and administration processes. It may also reflect greater exposure to medication-related procedures in patients receiving multiple drugs. In addition, patients receiving polypharmacy are often clinically more complex, which may contribute to higher observed error rates. Nevertheless, these explanations remain speculative, as the included studies did not provide sufficient information on drug classes, dosing frequency, or disease severity. Therefore, further research is needed to clarify the relationship between polypharmacy and medication errors and to explore potential underlying mechanisms.

Limitations

This study has several limitations. Although uniform inclusion criteria were applied, the definitions and classification systems for medication errors varied across the included studies. This may have led to misclassification bias, as certain error types may have been included in some studies but excluded in others. In addition, only studies published in English were included, which may have resulted in the omission of relevant evidence published in other languages, potentially limiting the global generalizability of the findings. Substantial heterogeneity was observed across the included studies, which may limit the interpretability and generalizability of the pooled estimates. Furthermore, only 3 outcomes were quantitatively synthesized, including the proportion of patients experiencing medication errors, prescription error rates, and administration error rates. Although some studies reported additional types of medication errors, such as dispensing errors and reconstitution errors, the limited number of studies and inconsistencies in reporting prevented meaningful meta-analysis of these outcomes. Therefore, the findings may not fully capture the overall burden of all types of medication errors in hospitalized pediatric patients. Future studies should adopt more standardized reporting frameworks for different types of medication errors to enable more comprehensive evidence synthesis.

Conclusions

The findings of this study indicate that medication errors remain a significant patient safety concern among hospitalized pediatric populations worldwide. Prescription errors and administration errors are the most frequently reported and relatively well-evidenced types of medication errors, and a substantial proportion of hospitalized pediatric patients experience at least 1 medication error. Intravenous administration, hospital stay longer than 5 days, and the prescription of 3 or more medications may be associated with an increased risk of medication errors, suggesting that treatment-related factors are closely linked to medication safety in pediatric inpatients. However, these findings should be interpreted as observational associations rather than causal relationships. These results highlight the importance of strengthening medication safety practices in pediatric inpatient settings to improve treatment quality and patient safety. Future research is needed to further investigate less-studied types of medication errors, such as dispensing and

XSL•FO
RenderX

reconstitution errors, to provide a more comprehensive understanding of the overall burden and to support the development of targeted interventions.

Abstract

Background: Sickle cell disease (SCD) is a genetic blood disorder affecting millions globally, with life-threatening complications, and most patients live in sub-Saharan Africa. Particularly, children with SCD have a high risk of stroke. Although early screening for stroke could help prevent many cases, access to effective stroke screening remains limited in low-resource settings (LRS). Existing traditional approaches are highly operator-dependent, costly, resource-intensive, or difficult to deploy at scale in pediatric care. These limitations highlight the urgent need for accessible, scalable, and child-appropriate stroke screening and assessment tools suitable for low-resource health care contexts.

Objective: The aims of this systematic literature review are to (1) uncover system-level barriers affecting stroke screening accessibility for patients with pediatric sickle cell disease (PSCD) in LRS, including underserved contexts within high-income countries; (2) identify existing and emerging stroke screening and assessment technologies and their implementation characteristics, such as feasibility, scalability, portability, and training requirements; and (3) propose a user-centered mobile health (mHealth) framework for stroke screening that improves accessibility and feasibility in resource-constrained health care settings.

Methods: PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) guidelines were followed to organize the search process. A systematic search was conducted using an advanced query and defined eligibility criteria in the academic databases of PubMed, IEEE Xplore, Wiley Online Library, and Google Scholar. Studies published in English between January 1, 2021, and October 31, 2025, were selected. Collected data were arranged in a preformatted Microsoft Excel spreadsheet for analysis. Risk-of-bias assessment was performed using various risk-of-bias assessment tools because of the heterogeneity of the included studies. Narrative synthesis was used for data synthesis.

Results: The literature search initially identified 1465 studies, of which 28 (2%) were selected for analysis. Among the 28 studies, 10 (36%) focused on stroke screening accessibility for patients with PSCD in either low- and middle-income countries or other income-level countries for LRS, and 18 (64%) outlined key features and the feasibility of stroke screening technologies. Identified barriers were organized into 4 major categories (workforce and training constraints, health care system and infrastructure barriers, sociocultural and awareness factors, and economic and logistical constraints), emphasizing difficulties in accessing stroke screening in LRS. Additionally, existing and emerging stroke screening technologies were classified into 5 groups: nonimaging, imaging, light-based optical spectroscopy, biomarker-based, and artificial intelligence– and machine learning–based mHealth wearable approaches. Finally, a comprehensive mHealth app is proposed for an easy-to-use screening experience to address stroke screening challenges for patients with PSCD in LRS.

Conclusions: This study contributes to identifying major barriers to stroke screening in LRS and highlights key characteristics of stroke screening solutions that can be used in the future. It also contributes to the design of a holistic mHealth solution for implementing stroke screening clinical care for patients with PSCD in LRS.

Introduction

Background

Sickle cell disease (SCD) is a genetic blood disorder affecting millions of people globally, most of whom live in sub-Saharan Africa. About 75% of patients with SCD are from this region and experience high mortality rates, with an estimated 50% to 90% of affected children dying before the age of 5 years due to infections or life-threatening complications [1,2]. Children with SCD often experience severe complications. Studies indicate that about 11% of children with SCD in these regions experience stroke by the age of 20 years [3,4]. For instance, each year, at least 20,000 babies are born with SCD in Uganda, and up to 80% of these children do not survive beyond the age of 5 years because of complications and limited access to adequate health care [4,5]. Weak health care infrastructure, high costs, and limited availability of specialized medical personnel in these low-resource settings (LRS) further compound the challenges faced by these children. Particularly in rural regions, health care disparities present significant obstacles [5-7]. Despite ongoing efforts, mortality among children with SCD remains high because of inadequate and delayed stroke screening, emphasizing the urgent need for affordable and accessible solutions in LRS [5,8].

Several stroke screening tools exist for pediatric patients with SCD, differing in mechanism, accessibility, and clinical requirements. These stroke screening and assessment technologies include nonimaging techniques such as transcranial Doppler (TCD), the current gold standard; imaging methods such as magnetic resonance imaging (MRI) or magnetic resonance angiography (MRA); biomarker-based approaches; light-based optical spectroscopy techniques such as speckle contrast optical spectroscopy (SCOS), an emerging noninvasive technology; and artificial intelligence (AI)- and mobile health (mHealth)-enabled solutions for early stroke detection.

Traditional approaches, such as TCD ultrasonography, are the gold standard for stroke screening in pediatric sickle cell disease (PSCD) and can assess stroke risk in children with SCD aged 2 to 16 years [9]. Few centers in sub-Saharan Africa have the neuroradiology facilities needed to conduct TCD screenings. A clinical trial in Nigeria revealed that only around 3000 TCD assessments were performed out of 40,000 children needing screening, covering less than 8% [10]. Regular TCD detection of abnormal blood flow in the brain has proven effective in reducing stroke incidence in these children [11]. Studies have shown that consistent TCD screening can drastically lower stroke rates [3,12]. However, TCD has 2 major drawbacks: its operation is highly dependent on the expertise of operators, and although it is effective for assessing major brain arteries, it is not suitable for examining blood flow in smaller or specific parts of the brain [13]. For these reasons, despite its efficacy, TCD is still not widely implemented in resource-limited settings.

MRI or MRA is another crucial tool for stroke screening, delivering detailed images that reveal silent cerebral infarcts (SCI) and other cerebrovascular problems [14]. Research shows that MRI provides a broader view of cerebrovascular changes than TCD, leading to earlier interventions and better outcomes [15]. However, MRI is often unavailable in low-resource areas because of its high cost and lengthy availability procedures [16]. Moreover, the need for dye contrast and sedation in children adds complexity to its use. Hence, more affordable and less cumbersome imaging techniques are necessary as alternatives to MRI [14].

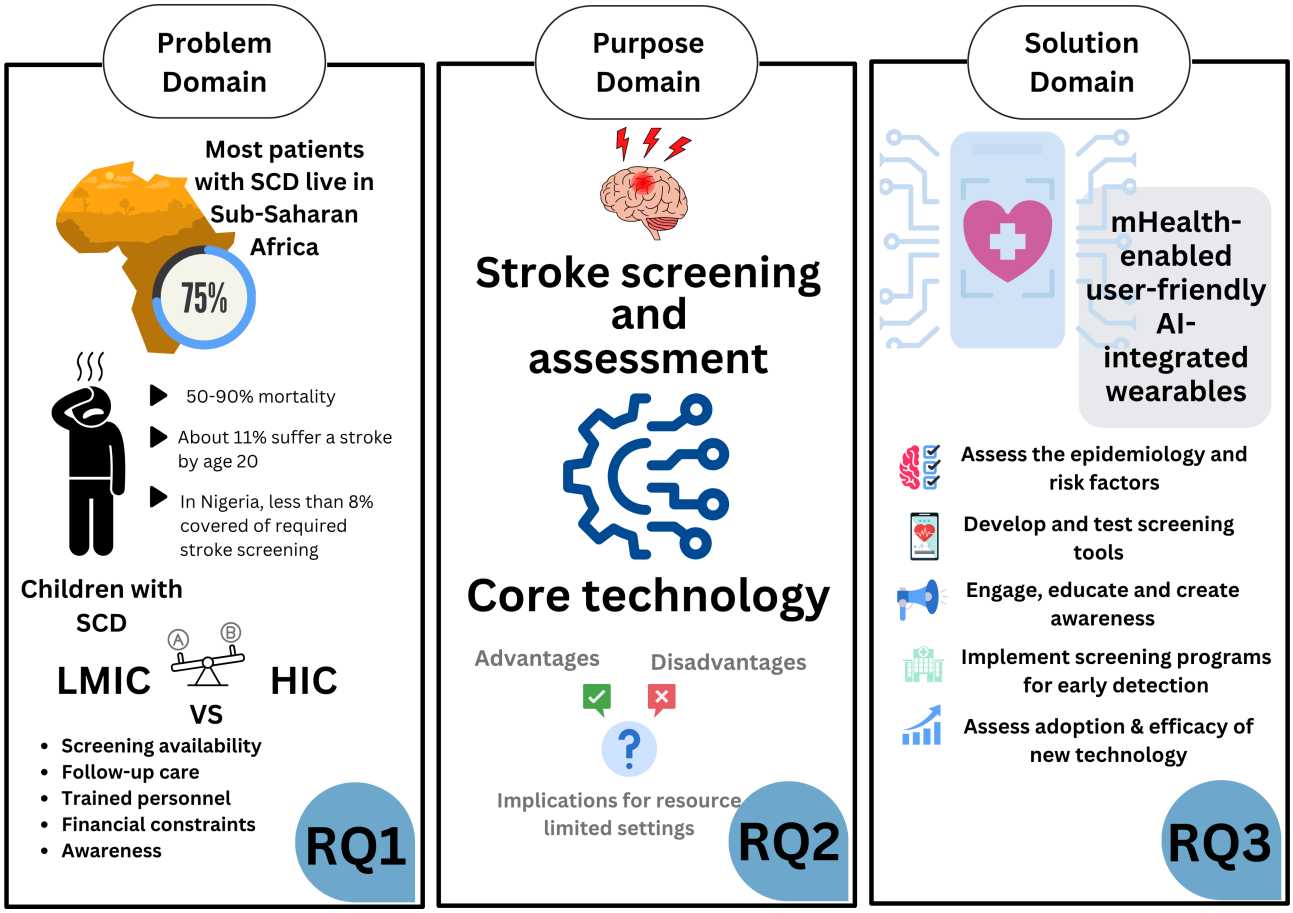
Recent advances in biomarker and genomic research now enable stroke risk assessment in patients with SCD [17]. Biomarker screening quantifies proteins and inflammatory markers, while genomic screening identifies genetic variations linked to susceptibility [18]. However, research on biomarkers and genomic screening for stroke prevention in SCD is ongoing [19].

Light-based SCOS solutions have shown promise in noninvasively assessing stroke risk [20]. Although this approach demonstrates significant potential for accessible and scalable stroke risk assessment, SCOS remains an emerging technology that requires further clinical validation for real-world use [21].

In addition, emerging technologies, such as wearable devices, have great potential for managing SCD because they allow continuous monitoring of vital parameters, such as oxygen saturation and heart rate [22,23]. These devices can alert both patients and health care professionals, enabling timely interventions before complications become life-threatening [24]. Although wearable devices vary in affordability, their continuous use may be impractical in resource-limited settings because of factors such as discomfort from wearing them all the time, the need for regular charging, and unreliable access to electricity [25].

mHealth technologies can significantly impact the management of SCD, especially in LRS [26]. For instance, mobile apps can monitor symptoms such as pain episodes [27,28], track disease progression, and enable timely interventions while also supporting patient engagement [29-31]. Overall, mHealth solutions have great potential in preventing chronic diseases because they can continuously track vital signs such as oxygen saturation and heart rate, providing real-time health information for improved disease management in critical situations [32].

Nevertheless, despite the great potential of mHealth solutions, significant gaps remain, particularly regarding their application to SCD [33,34]. Additionally, it is imperative to identify the



XSL•FO
RenderX

barriers that impede the adoption of these mHealth solutions in LRS [35]. Furthermore, these mobile apps could foster better patient engagement in care by encouraging patients to actively participate in managing their condition [36-38].

Objective

Therefore, this study aims to explore the key barriers to stroke screening implementation for pediatric patients with SCD in LRS. We examine the feasibility of conventional and emerging practices for stroke screening assessment and investigate how a more modular, AI-enabled mHealth solution can promote early detection and management, support patient involvement, enhance monitoring, and improve overall health outcomes for pediatric patients with SCD. The findings of this systematic literature review are centered around the following 3 research questions, as illustrated in Figure 1.

Figure 1. Objective of this study and research question (RQ) generation, organized around the problem domain, purpose domain, and solution domain. AI: artificial intelligence; HIC: high-income country; LMIC: low- and middle-income country; mHealth: mobile health; SCD: sickle cell disease.

The study addressed the following research questions (RQs) as follows:

1. Problem domain (PSCD stroke): What are the key barriers influencing the implementation of stroke screening for patients with PSCD in LRS, including both low- and middle-income countries (LMICs) and resource-constrained contexts within other income-level countries?
2. Purpose domain (stroke screening and assessment): What existing and emerging stroke screening and assessment technologies have been evaluated in individuals with PSCD or broader populations with stroke, and what implementation characteristics (feasibility, scalability, portability, and training requirements) are relevant to their potential use in PSCD stroke screening?
3. Solution domain (addressing aims through mHealth solutions): How can an integrated, user-centered mHealth-based stroke screening framework be proposed to address accessibility barriers and support early stroke detection and follow-up care for patients with PSCD in LRS?

Methods

Overview

This systematic review was conducted according to the PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) guidelines (Checklist 1). This review was registered with PROSPERO (CRD420251172487) and the full protocol can be accessed through the PROSPERO database. No amendments to the protocol were made following registration.

Eligibility Criteria

Studies were eligible for inclusion if they met the population, intervention, comparison, and outcome (PICO) criteria outlined in Table 1. Table 1 summarizes the inclusion and exclusion criteria based on the PICO framework, as described in Textbox 1.

XSL•FO
RenderX

Table . Summary of inclusion and exclusion criteria.

Criteria	Inclusion criteria	Exclusion criteria
Population	• Pediatric patients (<18 y) at risk of stroke and diagnosed with SCD[a]. • Studies not exclusively focused on PSCD[b] were included only if they provided indirect, contextual, or technology-enabling evidence relevant to stroke screening implementation in PSCD or low-resource settings.	• Studies not focusing on stroke screening among patients with SCD. • Studies focusing exclusively on adult populations without relevance to pediatric or implementation contexts.

Intervention	• Any stroke screening or assessment method, including:
	  • Imaging: MRI[c] and MRA[d]
	  • Nonimaging: TCD[e]
	  • Laboratory biomarkers
	  • Optical spectroscopy or SCOS[f] tools
	  • Wearable devices
	  • mHealth[g] tools
	  • AI[h]- and ML[i]-based stroke assessment models
	• Studies not exclusive to PSCD were included only when they provided insights into implementation, scalability, or accessibility, offering possibilities for adaptation in stroke screening of PSCD in low-resource settings.
		• Studies unrelated to screening interventions (treatment-only studies).

Comparison	No comparator was required because the focus was on narrative and thematic synthesis.	• N/A[j]

Outcome	• Reports on at least one outcome related to:
	  • Screening feasibility or accessibility
	  • Accuracy or reliability
	  • Workflow or training requirements
	  • Implementation barriers or facilitators
	  • Portability, cost, or infrastructure needs
		• Studies not reporting any outcome related to screening implementation or feasibility.

Study design	• Quantitative, qualitative, mixed methods, or observational studies. • Retrospective cohort studies, cross-sectional studies, implementation studies, narrative reviews, systematic reviews, or technical feasibility studies. • Peer-reviewed journal articles or conference papers. Preprints were included only when they provided unique technology-enabling insights not yet available in peer-reviewed literature and were clearly labeled as preprints. • Published between January 1, 2021, and October 31, 2025.	• Editorials, interviews, comments, unstructured observations, and position papers.

[a] SCD: sickle cell disease.

[b]PSCD: pediatric sickle cell disease.

[c]MRI: magnetic resonance imaging.

[d]MRA: magnetic resonance angiography.

[e]TCD: transcranial Doppler.

[f]SCOS: speckle contrast optical spectroscopy.

[g]mHealth: mobile health.

[h]AI: artificial intelligence.

[i]ML: machine learning.

[j]N/A: not applicable.

Textbox 1. Population, intervention, comparison, and outcome (PICO) framework for search query generation

Population

- Direct: pediatric patients (<18 y) who are at risk of stroke, particularly diagnosed with SCD.
- Indirect: Broader populations with stroke or neurological disorders were included only when studies provided indirect, technology-enabling, or contextual evidence relevant to stroke screening implementation in low-resource settings.

Intervention

- Studies examining stroke screening or assessment methods, including imaging (magnetic resonance imaging and magnetic resonance angiography), nonimaging approaches (transcranial Doppler), blood biomarkers, laboratory markers, wearable devices, mobile health tools, artificial intelligence–and machine learning–based technologies, or emerging screening modalities

Comparison

- No comparator was required because the focus was on narrative and thematic synthesis.

Outcome

- Studies reporting on screening feasibility, accessibility, accuracy, workflow processes, implementation challenges, barriers, facilitators, or overall effectiveness of stroke screening methods.

Definition of LRS

In this review, LRS was defined by the health care delivery context in which the essential capacity for routine stroke screening is hindered by a functional lack of medical infrastructure, specialized workforce, accessible funding for screening, or socioeconomic disparities [39]. This is a setting-level construct and may occur in both LMICs and underserved contexts within high-income countries (HICs) and other income-level countries. Country income status, such as LMIC, HIC, or other income-level countries, was recorded separately as a national-level descriptor.

Operationalization of Resource Setting

Although national income categories (LMIC or HIC) are frequently used as proxies for resource context, they do not capture the full range of constraints affecting health care delivery. Existing studies conceptualize that "LRS" consists of one or multiple interconnected domains of constraints, such as financial pressure, suboptimal health care service delivery, underdeveloped infrastructure, paucity of knowledge, research challenges and considerations, restricted social resources, geographical and environmental factors, human resource limitations, and the influence of beliefs and practices [39]. Using this concept, studies were classified as conducted in LRS if one or more system-level challenges hindered the routine delivery of stroke screening during the full-text screening and data extraction process. Although studies were initially tagged as conducted in LMICs or HICs using World Bank income classifications, the final classification was guided by this system-level conceptual framework rather than country income alone.

Database Selection and Search Strategy

The search was conducted in electronic databases including PubMed, Wiley Online Library, IEEE Xplore, and Google Scholar. A predefined search strategy, incorporating both Medical Subject Headings (MeSH) terms and free-text keywords, was used. The search terms were developed to capture literature related to stroke screening barriers, particularly those related to PSCD, stroke screening technologies, mHealth apps, and stroke screening challenges in LRS. Studies published in English between January 1, 2021, and October 31, 2025, were included. An advanced search string was built to search the databases. Search strategies were employed to align with the research questions, ensuring comprehensive coverage of the relevant literature.

The advanced search string used in this search was ((“stroke screening” OR “stroke risk assessment” OR “stroke prevention”) AND (“pediatric” OR “children” OR “child” OR “adolescent”) AND (“sickle cell disease” OR “SCD” OR “sickle cell anemia”) AND (“barriers” OR “enablers” OR “implementation” OR “training”)) OR ((“stroke screening” OR “stroke risk assessment” OR “stroke prevention”) AND (“TCD” OR “Transcranial Doppler” OR “mobile health” OR “mHealth” OR “wearable technology” OR “wearables” OR “wearable” OR “artificial intelligence” OR “AI” OR “MRA” OR “MRI” OR “Magnetic Resonance” OR “machine learning” OR “ML” OR “blood biomarkers” OR “biomarkers”)) (With filter in PubMed: Free full text filter, Wiley online library: Open Access Content).

Resource-setting terminology such as “low-resource,” “resource-limited,” “underserved,” or “resource-constrained” was not used as a mandatory search filter because these labels are not standardized and are applied inconsistently across disciplines and regions and are often absent from titles and abstracts. Instead, identification of LRS was prespecified as part of the full-text screening and data extraction process, using predefined system-level criteria described in the “Eligibility Criteria” section. This approach was used to avoid missing relevant studies while ensuring systematic and reproducible classification of the resource context.

Selection Process

The screening process was conducted according to the PRISMA framework [40]. Two reviewers (NJ and NA) independently conducted the literature screening process. During the identification step, we gathered our search results from the selected databases and exported them into the reference

XSL•FO
RenderX

management tool Zotero (Corporation for Digital Scholarship) to remove duplicates [41]. During the screening and eligibility steps, a title-based screening was conducted using keywords derived from the advanced search queries. Following this, the screening was conducted based on an abstract review. Finally, studies meeting the initial criteria were subjected to full-text review based on the inclusion and exclusion criteria. Both reviewers performed these steps. Discrepancies were resolved through discussion or adjudication by a third reviewer (NS).

Risk-of-Bias Assessment

Risk-of-bias (RoB) assessment was conducted to evaluate the methodological quality of the included studies. Because the review comprised diverse study designs, including qualitative, quantitative, mixed methods, and technology-focused feasibility studies, the appropriate appraisal tools were applied accordingly. We used the Joanna Briggs Institute (JBI) Qualitative, JBI Analytical Cross-Sectional, JBI Text and Opinion, JBI Systematic Review and Research Syntheses, Newcastle-Ottawa Scale Cohort, Quality Assessment of Diagnostic Accuracy Studies–2 (QUADAS-2), Prediction Model Risk of Bias Assessment Tool (PROBAST), RoB 2.0, and Mixed Methods Appraisal Tool (MMAT; McGill University) for RoB assessment purposes (Multimedia Appendix 1). The assessment focused on key domains, including clarity of aims, methodological rigor, sampling, data collection, analytical transparency, and relevance to clinical or technological implementation. Studies were evaluated independently by 2 reviewers (NS and NA). Disagreements between the 2 reviewers were resolved through discussion.

Data Extraction

Data extraction was performed independently by 2 reviewers using a standardized Microsoft Excel form. The extracted data included study characteristics (author, year, country, study design, sample size, and population type; Multimedia Appendix 2). We also extracted study details and intervention details (resource settings, stroke screening accessibility challenges, barrier categories, tool type, tool characteristics, training requirements, outcomes, and challenges; (Multimedia Appendices 3 and 4). Extracted data were cross-checked for consistency and completeness. Due to the variation in methodologies across studies, conducting a meta-analysis was considered unsuitable. Instead, information was narratively synthesized. Data extraction was conducted manually from a total of 28 included studies (27 peer-reviewed studies and 1 preprint) following the identification and selection process outlined in the PRISMA framework.

Data Synthesis

For this systematic literature review, due to the heterogeneity in interventions, outcomes, and contexts, we employed narrative synthesis, as a meta-analysis was not feasible based on the reviewed studies. As this review did not involve statistical hypothesis testing or meta-analysis, no *P* values were reported. No statistical effect measures, such as risk ratios or mean differences, were used because the outcomes were qualitative and heterogeneous. We narratively synthesized qualitative data related to our research questions, applied thematic analysis to categorize different barriers to stroke screening accessibility, and used narrative synthesis to highlight the key characteristics and outcomes of technological solutions for stroke screening. We categorized included studies as direct evidence, which pertains to clinical stroke screening or assessment in populations with PSCD, and indirect evidence, which pertains to barriers or technology-enabling studies from broader populations with stroke or neurological disorders. Barriers were extracted, coded, and categorized into thematic domains (workforce and training challenges, health care and infrastructure, sociocultural and awareness, and logistical and economic factors). Studies focusing primarily on stroke screening technologies were included whether they involved pediatric patients with SCD or broader populations with stroke. We included them because they demonstrated scalability, feasibility, or potential applicability as future screening tools for PSCD and interpreted them in terms of implementation and accessibility characteristics rather than as direct clinical validation in populations with pediatric SCD. Finally, we grouped stroke screening technology domains into 5 higher-level categories (nonimaging, imaging-based, light-based tools, biomarkers, and AI- and ML-based mHealth solutions).

Certainty of Evidence

Certainty of evidence was not assessed using grading of recommendations assessment, development, and evaluation (GRADE) or similar frameworks because the included studies were highly heterogeneous. We included descriptive outcomes rather than quantitative effect measures. As recommended for narrative syntheses, we provide contextual interpretation of findings rather than formal certainty ratings.

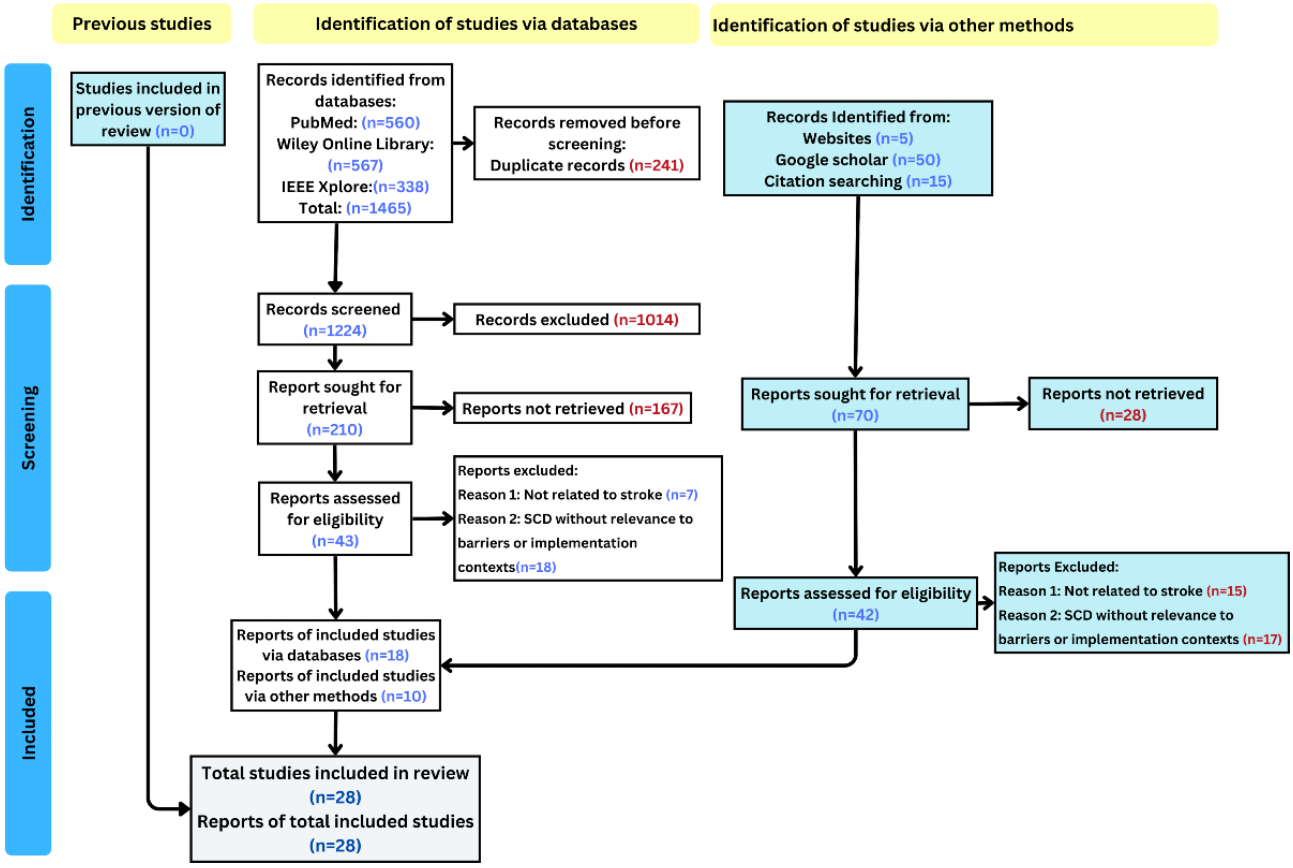
Ethical Considerations

Institutional review board approval was not required because the study did not involve human participant research. Zotero was used for screening and managing large volumes of literature while considering transparency and accountability, bias and fairness, privacy and confidentiality, as well as validity and reliability through continuous monitoring and the application of human judgment at each step.

Applicability of CHERRIES Guidelines

This study did not involve online surveys or web-based data collection. All analyzed data were obtained from previously published peer-reviewed studies, and 1 clearly identified preprint study was found through database searches. Therefore, the CHERRIES (Checklist for Reporting Results of Internet E-Surveys) guidelines are not applicable to this review.

Results



Overview

Initially, a total of 1465 studies were retrieved. After excluding 241 duplicates, 1224 studies remained. During the initial screening stage, 1014 studies were excluded after reviewing the study titles and abstracts. The full texts of the remaining 85 studies were reviewed, and 57 studies were excluded based on the eligibility criteria. Finally, 28 studies were included in the

XSL•FO
RenderX

systematic review. The final selection was recorded in a PRISMA flowchart in Figure 2.

Figure 2. PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) flowchart illustrating the selection of the included studies and the inclusion and exclusion criteria. SCD: sickle cell disease.

Study Characteristics

The 28 studies included in this review were conducted across diverse global regions (Multimedia Appendix 2). The largest number of studies was conducted in the United States (n=7, 25%) [11,15,20,42-45], followed by Nigeria (n=4, 14%) [46-49], India (n=4, 14%) [50-53], broader sub-Saharan Africa (n=2, 7%) [54,55], and China (n=2, 7%) [56,57]. Additional studies were conducted in Uganda (n=1, 4%) [14], Congo and Zambia (n=1, 4%) [58], Europe (n=1, 4%) [59], the Dominican Republic (n=1, 4%) [60], Taiwan (n=1, 4%) [18], Malaysia (n=1, 4%) [61], Iraq (n=1, 4%) [21], and globally (n=1, 4%) [62]. The publication years spanned from 2021 to 2025, with most studies (n=16, 57%) published between 2024 and 2025 [18,20,21,43-46,51-54,58-60,62,63], reflecting rapidly emerging research on stroke screening technologies and accessibility. Most studies were published in 2024 (n=9, 32%) [18,20,44-46,51-53,59], followed by 2025 (n=7, 25%) [21,43,54,58,60,62,63], 2022 (n=5, 18%) [14,48-50,55], 2021 (n=5, 18%) [11,42,47,56,61], and 2023 (n=2, 7%) [15,57]. Earlier foundational studies from 2021 to 2022 represented 10 (36%) of the included works [11,14,42,47-50,55,56,61].

Regarding research design, the studies used a wide range of methodologies, including qualitative descriptive studies (n=2, 7%) [42,46], retrospective observational analyses (n=4, 14%) [11,15,44,58], retrospective cohort studies (n=2, 7%) [18,43], narrative reviews (n=3, 11%) [54,56,62], cross-sectional studies (n=2, 7%) [14,59], mixed methods design and evaluation studies (n=2, 7%) [48,63], quantitative observational studies (n=2, 7%) [47,49], cluster randomized controlled trial (n=1, 4%) [61], the SACRED (Stroke Avoidance for Children in República Dominicana) trial (n=1, 4%) [60], an observational comparative study (n=1, 4%) [20], a systematic review (n=1, 4%) [55], and feasibility or technology evaluation studies (n=8, 29%) [21,44,45,50-53,57]. The focus of the studies also varied substantially, with a large proportion (n=10, 35%) centered on stroke screening accessibility and implementation challenges in LRS in both LMICs and HICs for children with sickle cell anemia (SCA) [42,43,46-49,54,55,59,60]. Additionally, 11 (39%) studies focused on novel or emerging stroke screening technologies, including MRI or MRA, optical and laser spectroscopy, blood biomarkers, AI-enhanced electrocardiogram (ECG), mobile apps, and AI-enabled multimodal tools [11,14,15,18,20,21,44,45,50-53,56-58,61-63]. Across these studies, population types ranged from children with SCA, caregivers, patients with stroke, healthy volunteers, and health care providers, allowing for a broad understanding of both accessibility barriers and technological advancements.

RoB Assessment

Based on the assigned tools and corresponding assessments, the overall RoB across the 28 included studies showed substantial variation by study design (Multimedia Appendix 1). Of the included studies, 43% (12/28) were assessed as having low RoB. A moderate RoB was identified in 32% (9/28) of the studies, primarily among retrospective observational,

XSL•FO
RenderX

cross-sectional, mixed methods, and observational study designs. In contrast, a high RoB was observed in 25% (7/28) of the studies, especially among feasibility and technology-based diagnostic accuracy studies assessed with QUADAS-2 and PROBAST, as well as more complex trial designs such as cluster randomized controlled trials. The distribution of RoB assessments across different study types and tools is summarized in Multimedia Appendix 1. As this review used narrative synthesis rather than quantitative meta-analysis, statistical assessments of reporting bias were not applicable. We qualitatively evaluated whether studies selectively reported outcomes or omitted key information. Several included studies provided limited or no details about performance, training requirements, or implementation challenges, suggesting a potential risk of reporting bias. Additionally, feasibility and technology development studies frequently emphasized only positive findings without fully reporting negative results. These limitations may lead to an incomplete representation of screening tool performance across settings.

Barrier Characteristics

Overview

Using narrative synthesis, barriers were grouped into 4 domains: workforce and training constraints, health care system and infrastructure barriers, sociocultural and awareness factors, and economic and logistical constraints. The synthesized major barriers to stroke screening accessibility in LRS are presented in Multimedia Appendix 3. Of the included studies, 36% (10/28) reported barriers related to stroke screening accessibility and its implementation in different health care settings. Table 2 provides an overview of how all identified barrier categories mapped onto 4 major thematic domains: workforce and training constraints, health care system and infrastructure barriers, sociocultural and awareness factors, and economic and logistical constraints.

Table . Major categories and their corresponding barrier categories.

Major category	Barrier categories included
1. Workforce and training constraints	Lack of trained staff, lack of specialists, lack of TCD[a] sonographers, lack of operator training, costly training, high patient volume, low provider knowledge or lack of knowledge, dependence on external examiners or visiting researchers, and limited clinical workforce capacity
2. Health care system and infrastructure barriers	Inadequate infrastructure, lack of machines or insufficient equipment, inefficient infrastructure, inefficient scheduling, coordination of appointments or fragmented care, no electronic medical records, screening services only in academic hospitals, limitations in hydroxyurea initiation or monitoring capacity, infrastructure gaps for sustained monitoring, poor health system organization, restricted TCD service availability, weak hospital leadership and partnerships, and limited neurological evaluation access
3. Sociocultural and awareness factors	Lack of awareness, cultural misconceptions, cultural disbelief, social burden, linguistic barriers, low understanding of SCA[b] or stroke prevention, need for community engagement, fear or distrust of medical interventions, caregiver education gaps, and low health literacy.
4. Economic and logistical constraints	Costly treatment, high cost of TCD, MRA[c], or CBT[d], transportation issues, logistical difficulties, high lifestyle demands, low funding, socioeconomic treatment variation, travel burdens, competing domestic responsibilities, geographic inaccessibility, out-of-pocket expenses for care, appointment scheduling conflicts, and caregiver time constraints.

[a]TCD: transcranial Doppler.

[b]SCA: sickle cell anemia.

[c]MRA: magnetic resonance angiography.

[d]CBT: chronic blood transfusion therapy.

Workforce and Training Challenges

As depicted in Multimedia Appendix 3, the lack of trained staff was reported in 60% (6/10) of the studies [46,47,54,55,59,60]. These studies indicated that stroke screening methods such as Doppler ultrasound and TCD require specialized training for operators, which is one of the major barriers to performing TCD screening in many LMICs. Several studies mentioned the need to train a specialized team to operate TCD, while others suggested training existing physicians and nurses to conduct the screening method, thereby reducing the need for specialists. From the 10 studies, 1 (10%) reported a lack of specialists [48] and 1 (10%) reported a lack of TCD sonographers [49].

Health Care Systems and Infrastructure

Thirty percent (3/10) of the studies highlighted inadequate infrastructure [47,54,55], and 20% (2/10) reported complex health care as a major health care system and infrastructure-related barrier [43,60] (Multimedia Appendix 3). Many rural and remote areas lack adequate infrastructure to perform screening procedures due to lack of equipment, poor coordination of scheduling, and a lack of laboratories to perform required tests. Additionally, follow-up care is inconsistent due to transportation difficulties and health care system inefficiencies, even when screenings are completed [42,48].

XSL•FO
RenderX

Sociocultural and Awareness

Forty percent (4/10) of the studies reported that a lack of awareness among patients and health care providers indicates that their knowledge of the importance of stroke screening is significantly low [46,55,59,60] (Multimedia Appendix 3). Health care providers are not aware of the annual TCD screening, and their lack of knowledge about stroke symptoms and risk factors further results in delayed diagnosis and treatment. Most of the time, caregivers are also not aware of the importance of early detection and risk factors, which diminishes the effectiveness of screening programs. Additionally, 40% (4/10) of the studies revealed that social burden and cultural disbelief contribute to reduced stroke screening assessments [46,49,54,55].

Economic and Logistical Challenges

Fifty percent (5/10) of the studies identified costly treatment as a primary barrier [43,47,49,55,60] (Multimedia Appendix 3). From the 10 studies, 1 (10%) revealed costly operator training [48], 1 (10%) revealed costly TCD examination [49], and 1 (10%) revealed costly blood transfusion therapy [49]. Additionally, 1 (10%) study reported that many public health care systems lack the funding essential to subsidize these costs [59]. In some LMICs, the cost of screening depends on patients' personal expenses, further limiting accessibility.

Disparities of Stroke Screening Access in LRS, HICs, and LMICs

From Multimedia Appendix 3, a clear disparity exists in stroke screening accessibility across low-resource environments in both LMICs and LRS in HICs. Evidence from LMICs shows that shortages of trained personnel, limited availability of TCD machines, fragile health care infrastructure, and high out-of-pocket costs consistently restrict early stroke detection among children with SCA. Caregivers also face substantial financial and social burdens, along with inadequate awareness of stroke risks and limited community outreach mechanisms in LMICs. Infrastructure challenges, such as shortages of electronic medical records, insufficient specialists, and dependence on external partnerships, hinder the accessibility of stroke screening. Similarly, LRS within HICs demonstrated parallel barriers; however, they mostly face logistical difficulties in scheduling and coordinating care in already established health care facilities. Other significant barriers in HICs include transportation limitations and high lifestyle demands that interfere with attending appointments. Socioeconomic disadvantages are strong in HICs and are strongly associated with inconsistent access to screening, reduced follow-up, and poorer biological risk markers, reflecting systemic inequities despite comparatively advanced health systems. On the other hand, LMICs face widespread difficulties in accessing stroke screening facilities. In both contexts, limited trained staff, operational inefficiencies, and socioeconomic barriers are major concerns regarding reduced early stroke prevention.

Existing Core and Emerging Stroke Screening Technology Characteristics

Narrative synthesis from 64% (18/28) of the included studies revealed 5 distinct categories of stroke screening technologies [11,14,15,18,20,21,44,45,50-53,56-58,61-63] (Multimedia Appendix 4). At a higher level, we could categorize as follows: (1) nonimaging technology-based tools, such as TCD, (2) imaging-based modalities, such as MRI and MRA, (3) light-based optical spectroscopy-based devices, including SCOS and laser-based approaches, (4) biomarker-based and physiological signal-based approaches, such as routine blood test-derived markers, and (5) AI- and ML-enabled mHealth and wearable tools. These technologies could overlap with each other for stroke screening purposes. The last 3 categories could be considered emerging technologies as they are still progressing toward validation.

Existing Technologies

Of the included studies, 7% (2/28) reported that nonimaging TCD is suitable for early-age screening and has a low technical failure rate but is highly specialized and operator-dependent [11,58]. Similarly, 7% (2/28) of the studies focused on magnetic field-based imaging screening, such as MRI and MRA stroke screening tools, which produce high sensitivity and detailed cerebral imaging. However, these tools require radiologists to perform and interpret the results [14,15] (Multimedia Appendix 4). They are limited by high cost, inadequate infrastructure, and portability issues and are recommended only for children in serious condition.

Emerging Technologies

Light-based optical spectroscopy devices are among the emerging stroke screening technologies in 7% (2/28) of the studies. These devices are lightweight and require only basic instructions [20,21]. Similarly, 7% (2/28) of the studies examined blood biomarker-based stroke screening, whose main advantage is that it can be conducted using clinically accessible, routine blood test data [18,44]. AI and ML were used in 29% (8/28) of the studies to enhance mobile and wearable apps, as well as to improve blood biomarkers-based stroke detection or risk prediction [18,45,50,52,53,56,62,63]. These technologies showed promise in terms of accessibility, real-time analysis, and scalability. Wearable-based technologies for stroke screening were reported in 11% (3/28) of the studies [56,57,62], while 18% (5/28) examined mobile app–based stroke screening tools [45,51,52,61,63]. In addition, ECG-based cerebral blood flow monitoring devices were evaluated in 4% (1/28) of the studies and demonstrated strong performance in real-time monitoring and stroke prediction [50].

Cost, Portability, Scalability, and Infrastructure Needs

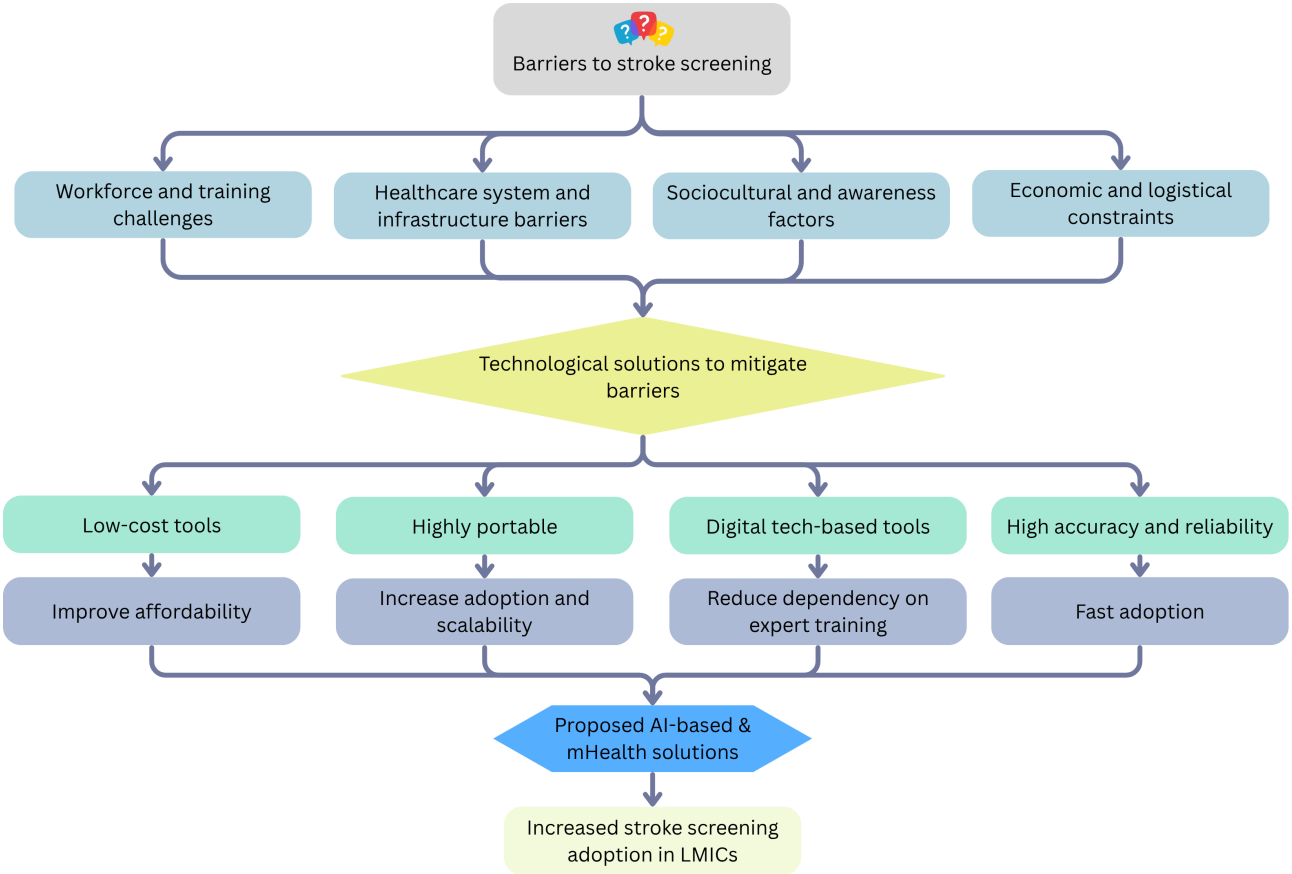
Low-cost stroke screening methods were reported in 25% (7/28) of the studies [11,20,21,44,56,58,61]. Among these studies, 7% (2/28) involved TCD-based stroke screening [11,58], 7% (2/28) examined light-based optical devices [20,21], 4% (1/28) examined blood biomarker-based screening methods [44], 4% (1/28) evaluated mobile-based solutions [61], and 4% (1/28) evaluated wearable solutions [56], which were considered highly suitable for LRS. In contrast, 7% (2/28) of the studies mentioned MRI or MRA-based techniques as high-cost [14,15], and these imaging technologies require significant infrastructure and trained specialists, making scalability challenging in LRS. Furthermore, 7% (2/28) of the studies are highly portable as they are lightweight, light-based imaging technologies [20,21].

XSL•FO
RenderX

Finally, 36% (10/28) of the studies show potential for highly scalable tools, including mobile-based technologies [45,51,52,61,63], wearable-based technologies [56,57,62], and biomarker tests [18,44], which are easily deployable in LRS due to their minimal to no infrastructure requirements.

Training Requirements

High dependency on the machine operator was mentioned in 14% (4/28) of the studies [11,14,15,58]. Emerging technologies such as light-based optical spectroscopy, blood biomarkers, mobile-based tools, AI-based systems, and wearables were reported in 50% (14/28) of the studies as being less operator-dependent and easily adoptable in LRS [18,20,21,44,45,50-53,56,57,61-63]. AI tools that are easily integrated with various devices and require little to no technical training were explored in 22% (6/28) of the studies, making them ideal for self-use or by basic clinical staff [18,45,52,53,62,63]. Mobile app devices and decision support systems, providing a new way for self-management of stroke screening, were reported in 18% (5/28) of the studies [45,51,52,61,63].



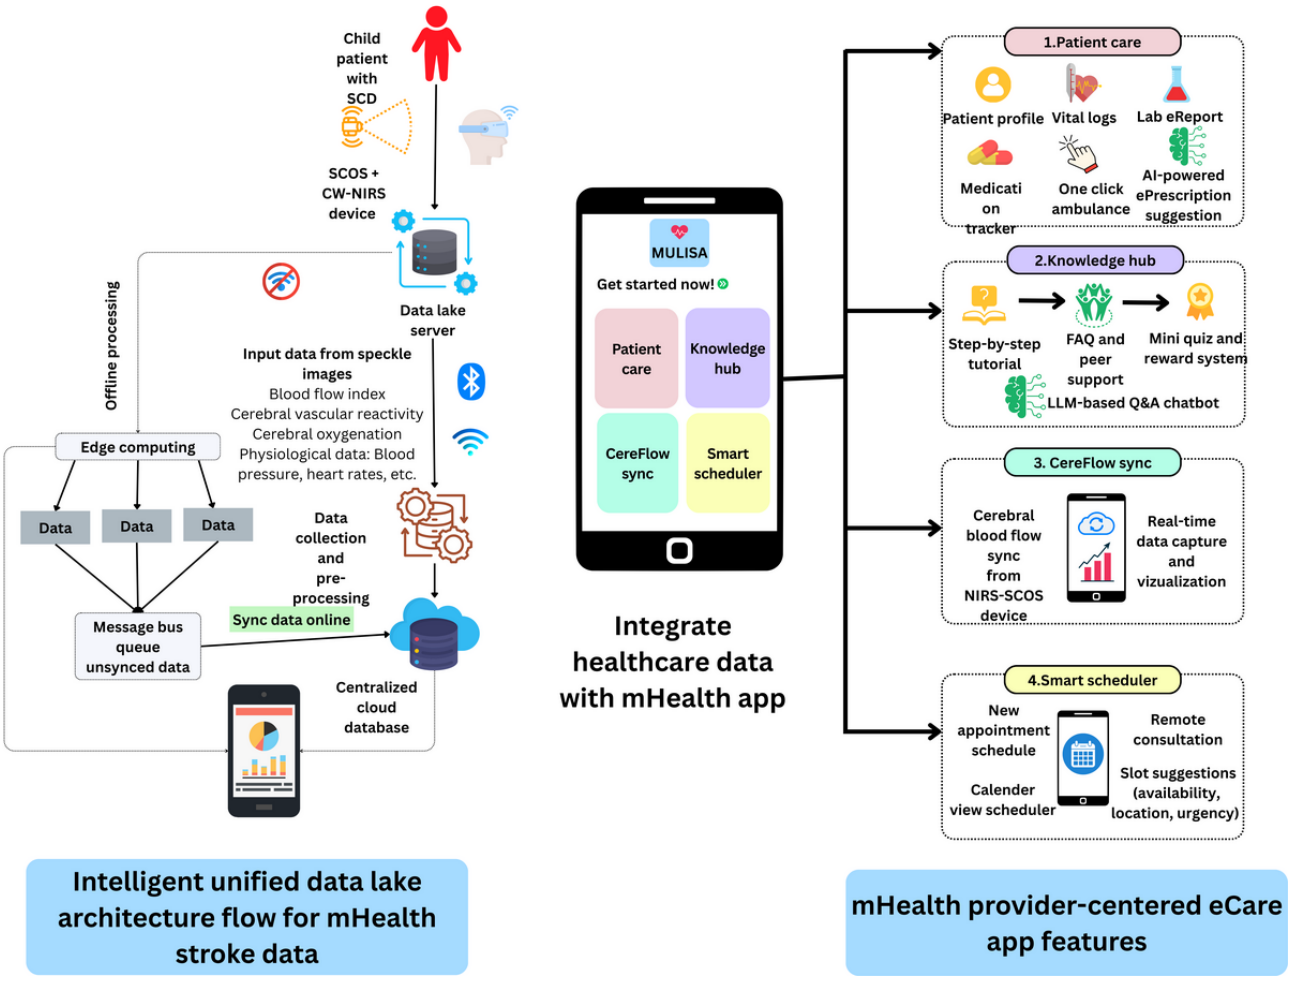
Outcomes and Challenges

Wearable-based studies showing potential for high scalability in the future were reported in 11% (3/28) of the studies [56,57,62]. AI- and ML-based studies showing an accuracy of around 90% were identified in 22% (6/28) of the studies [18,45,50,53,62,63]. An AI- and ECG-based stroke screening solution model with more than 90% accuracy was developed in 4% (1/28) of the studies [50]. An ML-based mobile app reporting around 88% user satisfaction during use was described in 4% (1/28) of the studies [63]. A multimodal mobile app demonstrating an accuracy of 80.25% was reported in 4% (1/28) of the studies [45] and 7% (2/28) of the studies focused on the implementation of TCD [11,58], which mentioned that TCD has a low technical failure rate of around 4.3% but encountered problems due to implementation challenges.

mHealth Solution From Identified Barriers and Technological Tools Characteristics

We integrate our findings from RQ1 and RQ2 to build a conceptual framework that illustrates how various barriers in LRS impact stroke screening accessibility and how different aspects of technological solutions for stroke screening can lead to an innovative approach that increases the adoption of stroke screening technologies in LMICs. The framework is illustrated in Figure 3.

Figure 3. Conceptual framework integrating the key barriers identified in research question (RQ) 1 with the benefits and addressing the limitations of stroke screening technologies from RQ2, aiming to develop an innovative mobile health (mHealth)–enabled solution for low-resource settings. AI: artificial intelligence; LMIC: low- and middle-income country.



This section addresses RQ3 by proposing a modular mHealth system specifically tailored to support stroke screening and care management in children with SCD. The system embraces a user-centered approach, emphasizing real-world health care provider workflows, intuitive mobile interfaces, and accessibility in low-resource environments. By analyzing barriers identified

XSL•FO
RenderX

from RQ1 and examining stroke screening technologies from RQ2, we suggest an end-to-end solution for stroke screening and assessment for SCD among pediatric patients. This solution will integrate a mobile app with dual-wavelength SCOS and continuous wave near-infrared spectroscopy (NIRS) devices, which will measure cerebral blood flow and oxygenation noninvasively, providing real-time, actionable insights about stroke risk into the portable mobile dashboard. This system will process real-time data, provide interactive clinical guidance and remote consultations, and enable health care providers to quickly assess a patient's condition by viewing user-friendly dashboards, allowing them to respond and provide care more easily [64]. Additionally, the solution will incorporate edge computing, making it accessible even in offline environments and ensuring stability in LRS. Overall, this innovative approach will ensure continuous monitoring, early intervention, and enhanced clinical decision-making, ultimately improving health outcomes for children with SCD. Figure 4 illustrates our novel mHealth system architecture designed to facilitate stroke screening and patient management, integrated with an NIRS-SCOS stroke screening tool. These features will be co-designed in accordance with user-centered guidelines [65], ensuring that the interface and data visualizations are both understandable and actionable, even for nonspecialist providers.

Figure 4. Modular unified lightweight intelligent stroke assistant (MULISA) mobile health (mHealth) system architecture consists of 5 major modules (data lake for raw data inputs, data processing unit, centralized server, artificial intelligence [AI] data analyzer, and main application module) and 3 supporting modules. FAQ: frequently asked questions; LLM: large language model; SCD: sickle cell disease; SCOS: speckle contrast optical spectroscopy; CW-NIRS: continuous wave–near-infrared spectroscopy.

Discussion

Principal Findings

This systematic review examined the multilevel barriers to PSCD stroke screening (RQ1), summarized existing and emerging screening technologies (RQ2), and explored opportunities for user-centered mHealth integration to address accessibility gaps in low-resource environments (RQ3).

Narrative synthesis allowed us to integrate diverse evidence and identify core barrier themes across settings, highlighting structural constraints and workflow gaps that must be addressed through integrated mHealth solutions. This review identified substantial barriers in stroke screening accessibility for patients with PSCD across LRS, driven largely by workforce challenges, limited infrastructure, awareness, and financial constraints (RQ1; Multimedia Appendix 3). Across LMICs and HICs, we found consistent themes related to a lack of staff, inadequate infrastructure, lack of knowledge, and financial constraints. These findings align with earlier regional studies reporting that TCD uptake remains low due to limited trained sonographers, insufficient radiology capacity, and fragmented care pathways [54,55]. It is also evident that economic limitations are among the most significant barriers in LMICs [49,55]. Procedures like

XSL•FO
RenderX

TCD, MRA, and chronic blood transfusion therapy are efficient stroke prevention methods but are often out of reach due to high costs [11,14,49]. Even when TCD equipment was implemented, services could not be scaled due to a lack of lab facilities, a proper appointment scheduling structure, and insufficient operational resources [47,54]. These studies also reveal that some programs fail to achieve sustainability despite initial investments due to systemic weaknesses in health care infrastructure and coordination. In HICs, cost is not reported as a dominant factor; however, operational and logistical inefficiencies, such as scheduling conflicts, limited radiology hours, and poor integration of stroke screening tools, affect screening adherence [42,43]. Cultural beliefs, socioeconomic factors, and low awareness about stroke prevention among patients' primary caregivers and health care providers reduce the possibilities of taking preventive measures in LRS in both LMICs and HICs [43,46,49,54,60]. Most people fear long-term dependency on medical treatments like blood transfusions, leading them to avoid taking medical help in the early stages of the disease [49].

To answer RQ2, we explored screening technologies and found out 5 major categories of stroke screening technologies (imaging, nonimaging, biomarkers, SCOS-based tools, and mHealth or AI solutions), each demonstrating unique strengths but varying widely in accessibility and feasibility. Furthermore, an exploration of both existing and emerging technologies related to stroke screening (Multimedia Appendix 4) highlights critical attributes, including cost, portability, scalability, infrastructure needs, training requirements, and outcomes. It reveals the significant potential of AI-driven mHealth solutions for the early diagnosis of stroke risk by analyzing the key characteristics of each stroke screening tool, particularly in resource-limited settings, and the flexibility of customizing mHealth solutions for patients with PSCD [45,52,53,63].

Finally, our findings underscore the need for an integrated, user-centered mHealth solution capable of responding to the identified barriers and leveraging the key functional attributes of emerging stroke screening tools for early stroke detection in patients with PSCD (RQ3). The potential impact of these barriers and screening tools, introduced in Figure 4, will help bridge gaps in early diagnosis, empower local health care workers, and promote timely follow-up care for critical conditions such as SCD. As this solution will be mHealth-based, it will be low-cost, highly portable, and scalable in LRS. A knowledge hub module will be incorporated to address the lack of knowledge and inadequate operator training in stroke screening assessments. This module will aid in decision-making by providing step-by-step instructions, a peer support system, and a large language model–based chatbot. AI will be used to provide advanced analytics on patient risk assessment reports by analyzing historical data [66]. User engagement will be promoted through the app, where we will design and assess the app's interactive dashboard built from collected stroke screening data from the SCOS device [67], support remote consultation, and include SCD-specific care recommendations, such as hydration tracking and pain episode logs [68]. Furthermore, the system's mobile-first architecture (using a Flutter frontend and Django backend) will ensure cross-platform compatibility and offline functionality, key advantages for deployment in rural or infrastructure-challenged areas. The whole solution will be incorporated with edge computing so that it will have consistent connectivity even in offline environments, which is a major requirement in LRS. Future field testing will involve pilot studies to evaluate usability, adoption rates, clinical effectiveness, and user satisfaction, to make this a real-world tool. Overall, this research demonstrates a promising path forward for scalable, user-centered mHealth solutions that can significantly improve pediatric stroke risk management in resource-limited settings.

Limitations

This review has several methodological limitations. There may be language and publication bias, as only English-language publications were included. Additionally, the exclusion of gray literature, conference abstracts, and non–English-language publications could mean that we have omitted valuable regional or local insights, especially from non–English-speaking LMICs, where relevant work might be found. Additionally, valuable information from other sources that are not indexed in major databases may be overlooked. Although the review followed PRISMA guidelines, screening and data extraction were independently conducted by two reviewers to minimize selection and interpretation bias. However, small differences in interpretation are likely to occur naturally.

This systematic review aimed to capture the most up-to-date stroke screening technologies; however, it has certain limitations. One of the primary concerns is the heterogeneity of the studies included in terms of their methodologies, the technologies evaluated, and the outcome measures used, which prevented us from performing a meta-analysis. As a result, this review was unable to determine which stroke screening technology is most closely linked to effective interventions.

Another notable limitation is related to the rapidly evolving and growing nature of artificial intelligence and mHealth technologies. Some of the most recent developments may not yet be available in peer-reviewed literature and, therefore, were excluded from our analysis. Furthermore, many studies focus on technical performance rather than evaluating real-world deployment, usability, and long-term sustainability.

Future Directions

There is a clear need for further research to understand the barriers present in LRS involving large populations. Emerging technologies like AI-based mobile apps stand out for their low cost and high portability, making them highly adoptable and scalable in LRS. Integrating mobile-based apps with stroke screening devices will increase the ability to detect unknown stroke signs early. Integrating AI with imaging technologies may offer future pathways to overcome some of the prevailing infrastructure and cost barriers, making imaging more accessible and enhancing diagnostic accuracy. Furthermore, additional research is needed to refine and validate emerging stroke screening technologies. Future work should also focus on improving the generalizability of these tools across diverse populations and different stroke severities, as well as enhancing the integration of these technologies with existing health care

XSL•FO
RenderX

systems. There is also potential for multimodal AI systems to provide a more comprehensive and accurate risk assessment for strokes, as well as the integration of mHealth systems with emerging technologies such as NIRS tools or ECG tools.

Conclusions

In this review, the authors have identified various key barriers limiting access to stroke screening for children with SCD in LRS and evaluated the sustainability of both standard and emerging technological solutions. This review revealed a wide array of prevailing tools that remain inaccessible due to several economic, cultural, and infrastructural barriers commonly encountered in LRS, as well as emerging stroke screening technologies that could be easily used in various health care settings. Additionally, this review demonstrated potential solutions for stroke screening and assessment, underscoring the promise of integrating mHealth solutions with portable devices and imaging systems. While significant advancements have been made in the development of stroke screening technologies, there still remains a critical challenge to ensure that these tools are accessible, accurate, and scalable in real-world settings. Finally, we uncovered an AI-enabled solution customized to address the identified barriers. This holistic solution offers a practical foundation to revolutionize stroke prevention and management, guide clinical implementation, and drive health innovation in the future, particularly in resource-limited environments.

Acknowledgments

The authors thank the mHealth Research Laboratory at Kennesaw State University for their contributions to this systematic review. The authors also appreciate the valuable input of our multidisciplinary collaborators who contributed to the conceptual development of the modular unified lightweight intelligent stroke assistant (MULISA) framework. The authors did not use generative artificial intelligence to write any portions of this manuscript.

Funding

This study was supported by Kennesaw State University Office of Research Grand Grant Challenge Fall 2024.

Data Availability

In this study, all data are generated or analyzed from previously published sources. The extracted data and findings are presented within the manuscript and as multimedia appendices. Additional information about procedures and data analysis is available from the corresponding author on reasonable request.

Abstract

Background: Adolescents with autism spectrum disorder (ASD) experience persistent barriers to accessing comprehensive and developmentally appropriate sexual health education. Conventional curricula often fail to reflect their cognitive, social, and communication needs, increasing vulnerability to misinformation and sexual exploitation. Digital health interventions offer a promising avenue to deliver tailored, interactive, and accessible learning experiences for adolescents with ASD.

Objective: This scoping review aimed to map and synthesize the evidence on digital health interventions designed to provide sexual health education to adolescents with ASD.

Methods: A scoping review was conducted using Arksey and O'Malley's framework, refined with Joanna Briggs Institute guidance and reported following the PRISMA-ScR (Preferred Reporting Items for Systematic Reviews and Meta-Analyses extension for Scoping Reviews) standards. In total, 6 databases (ie, PubMed, Scopus, CINAHL, ERIC, PsycINFO, and Web of Science) were searched from 2010 to June 2025. Eligible studies involved adolescents aged 10 to 19 years with ASD, used digital platforms to deliver sexual or reproductive health education, and were published in English. Two reviewers independently screened, extracted, and synthesized data using descriptive and thematic approaches.

Results: A total of 16 studies met the inclusion criteria. Most studies were conducted in high-income countries and delivered content through video-based, web-based, or mobile modalities. Key features associated with positive learning outcomes included personalization, strong visual interactivity, and caregiver involvement. Reported improvements focused on sexual knowledge, behavioral understanding, and user acceptability. However, methodological limitations were common, including small and nonrepresentative samples, a lack of standardized outcome measures, and minimal gender-specific or culturally adapted content. Notably, co-design with autistic adolescents and implementation in low- and middle-income countries was scarce.

Conclusions: Digital health interventions demonstrate promising early effectiveness for delivering inclusive, developmentally appropriate sexual health education to adolescents with ASD. To advance this field, future research must strengthen methodological rigor, include diverse and gender-balanced populations, use participatory design, and ensure cultural adaptability to support equitable access globally.

KEYWORDS

autism spectrum disorder; digital health; sexual education; adolescents; scoping review; PRISMA

Introduction

Adolescents diagnosed with autism spectrum disorder (ASD) often miss out on crucial sexual health education, despite ASD affecting more than 1% of young people worldwide [1]. The World Health Organization recognizes sexual health as a fundamental human right critical to psychosocial well-being [2]. Yet, adolescents with ASD commonly receive insufficient, delayed, or entirely absent sexuality education [3] during a developmental period marked by puberty, identity formation, and increasing social complexity.

Growing evidence shows that young people with ASD face distinct and systemic inequalities in sexual health education. These inequalities are characterized by (1) assumptions that individuals with ASD are asexual or permanently dependent, which lead caregivers and educators to avoid sexuality topics [4]; (2) curricula that overemphasize risk avoidance rather than fostering autonomy, intimacy, and healthy relationships [5]; (3) a lack of instructional approaches adapted to ASD-specific cognitive and behavioral characteristics, such as a preference for concrete, visual, and highly structured learning, and challenges with interpreting social cues and implicit norms [6]; and (4) limited access to peer-learning environments where informal sexuality knowledge is typically developed [7]. As a

XSL•FO
RenderX

result, adolescents with ASD experience greater exposure to harm, including a 2 to 3 times higher risk of sexual victimization (30% - 50% lifetime prevalence) compared with neurotypical peers [8,9], alongside difficulties recognizing consent and personal boundaries [10]. Despite these risks, adolescents with ASD often display developmentally typical sexual curiosity, which is frequently misunderstood as problematic behavior, further impeding their access to affirmative and accurate sexual health education [11].

Traditional school-based programs generally rely on abstract verbal instructions, implicit social rules, and group discussions [9], pedagogical methods that do not adequately address the processing preferences and social learning challenges characteristic of ASD. Although some adapted interventions using visual supports, role-play, behavioral modeling, and caregiver participation have shown potential benefits [10,12], they remain resource intensive, highly dependent on trained specialists, and often limited to high-income settings, thus restricting equitable scale-up [11,12].

Digital health technologies provide an opportunity to address these barriers specifically within the context of sexual health education. Mobile apps, interactive videos, and virtual learning environments can deliver content visually, sequentially, and at a self-paced rhythm aligned with ASD learning patterns [13]. Privacy features allow adolescents to engage with sensitive topics without fear of stigma or embarrassment [14], which is particularly important for those who struggle with discussing sexuality face-to-face. Additionally, cultural and linguistic adaptation can be built directly into platforms, supporting contextual relevance in settings where sexual health remains taboo or tightly regulated.

Despite these benefits, only a small number of digital interventions have focused specifically on sexual health for autistic adolescents. Reviews of technology-based learning for neurodiverse youth [13] and reviews of sex education for people with disabilities more broadly [14] have not examined the unique intersection of ASD-specific pedagogy, adolescent development, sexual content, and digital delivery. Moreover, implementation in low- and middle-income countries (LMICs) is largely absent. Limited digital infrastructure, lower availability of trained providers, and cultural discomfort surrounding discussions of sexuality create additional barriers to uptake and sustainability.

Given these gaps, this scoping review maps digital sexual health interventions for adolescents with ASD, describing digital modalities, educational foundations, implementation contexts, and reported outcomes. We also identify 3 cross-cutting gaps (ie, limited participatory co-design, underrepresentation of girls, and scarce implementation in LMIC settings), which are analyzed in the Discussion to inform future directions.

Methods

Study Design

This review follows the scoping methodology originally outlined by Arksey and O'Malley and later refined by Levac et al [15], incorporating the latest methodological recommendations from the Joanna Briggs Institute [16]. The reporting process adheres to the PRISMA-ScR (Preferred Reporting Items for Systematic Reviews and Meta-Analyses extension for Scoping Reviews) checklist [17].

Review Questions

The review aims to address the following questions:

1. What types of digital health interventions have been developed to deliver sexual health education to adolescents with ASD?
2. How are these interventions designed and implemented in practice?
3. What outcomes, such as educational, behavioral, or usability-related, have been reported?
4. What evidence gaps and contextual challenges emerge from the current literature?

Eligibility Criteria

The inclusion and exclusion criteria were developed based on the PCC (population, concept, context) framework recommended by the Joanna Briggs Institute Manual for Evidence Synthesis (Table 1).

XSL•FO
RenderX

Table . Inclusion and exclusion criteria.

PCC component	Inclusion criteria	Exclusion criteria
Population	• Adolescents aged approximately 10 - 19 y diagnosed with ASD[a]; OR studies involving young adults, caregivers, or practitioners if findings are directly relevant to adolescent sexual health education in ASD	• Studies involving only adults with ASD where findings lack relevance to adolescents • Studies focused solely on non-ASD neurodevelopmental disorders
Concept	• Sexual health education delivered in a digital format, including mobile apps, web platforms, video modeling, virtual simulations, digital social stories, or tele-education • Interventions focused on sexual knowledge, boundaries, consent, relationships, hygiene, or online safety	• Interventions unrelated to sexual health content • Tools designed exclusively for skill areas not linked to sexuality (eg, employment and general social skills)
Context	• Any educational, clinical, family, or community setting • All cultural and socioeconomic contexts	• Studies focused solely on institutional care settings without educational intent
Study design	• All empirical study types (RCTs[b], pilots, mixed methods, qualitative) and co-design or framework studies relevant to digital tools • Peer-reviewed journal articles	• Reviews, editorials, and commentaries without original data • Conference abstracts without full text
Language	• Published in English	• Non-English publications
Publication date	• 2010 - 2025	• —[c]

[a]ASD: autism spectrum disorder.

[b]RCT: randomized controlled trial.

[c]Not applicable.

Studies published from January 2010 to June 2025 were included because this period reflects major advancements in digital health technologies and their integration into health education, including sexuality education for neurodiverse populations. Earlier digital interventions lacked comparable accessibility and interactive features, making them less relevant to current implementation contexts. Only English-language publications were included due to resource and feasibility constraints in translating non-English texts. While this may introduce language bias, limiting the review to English publications ensured consistency in screening and methodological appraisal, although some evidence from non-English-speaking regions may be underrepresented.

Search Strategy

A comprehensive search was conducted across six major electronic databases: PubMed/MEDLINE, Scopus, CINAHL, ERIC, PsycINFO, and Web of Science. The search strategy combined controlled vocabulary (eg, Medical Subject Headings [MeSH] terms) with relevant free-text keywords related to ASD, adolescence, sexual health education, and digital health interventions. An example of the search string used in PubMed was as follows: ("Autism Spectrum Disorder"[MeSH] OR autism OR ASD) AND ("Adolescents"[MeSH] OR adolescent OR youth) AND ("Sex Education"[MeSH] OR sexual health) AND ("Digital Health"[MeSH] OR eHealth OR mHealth OR digital intervention). To enhance the comprehensiveness of the review, the reference lists of all included studies were manually screened for additional eligible articles that were not captured through database searches.

Study Selection and Screening Process

All retrieved citations were imported into EndNote for systematic deduplication. The remaining records were then uploaded into Rayyan, a web-based screening platform, to facilitate an organized and blinded review process. Before formal screening, both reviewers conducted a pilot calibration exercise using 20 randomly selected citations from the initial search results (n=243). This was done to refine operational definitions and ensure a shared understanding of the eligibility criteria. Once sufficient agreement was achieved, independent title or abstract screening proceeded for all remaining records. Following calibration, 2 independent reviewers screened titles and abstracts using predefined inclusion and exclusion criteria. Full texts were retrieved for all articles deemed potentially relevant. Discrepancies at any stage were discussed, and if consensus could not be reached, a third reviewer served as adjudicator. This multistep process strengthened the reliability and reproducibility of study selection.

Data Extraction

A structured and pilot-tested data extraction form was used to ensure consistent and comprehensive data collection across all eligible studies. Extracted information included authorship,

XSL•FO
RenderX

publication year, country of origin, study design, participant characteristics, digital modality and duration, theoretical or pedagogical frameworks, educational content and delivery strategies, outcome domains, key findings, and reported limitations or implementation barriers. Data extraction was performed independently by 2 reviewers. Any discrepancies in extracted information were resolved through discussion and consensus; when agreement could not be reached, a third reviewer was consulted to adjudicate. This process ensured accuracy and minimized individual reviewer bias throughout the synthesis.

Quality Appraisal

Although not mandatory in scoping reviews, a methodological quality assessment was conducted to enhance the interpretative rigor of the findings. The Mixed Methods Appraisal Tool (2018) was used to evaluate each study across 5 design-specific criteria. Two reviewers independently completed the appraisal, resolving any disagreements through discussion and third-reviewer adjudication when necessary. The appraisal was used to contextualize findings rather than to exclude studies.

Overall, the quality of included studies was moderate. Approximately one-quarter of the studies demonstrated high methodological quality (scores of 4/5), typically characterized by clearly defined outcomes and appropriate study designs, including randomized trials and multisite implementations. The majority of studies scored 3 out of 5, reflecting acceptable methodological rigor but common limitations, such as small sample sizes, lack of control groups, and short intervention durations. Lower-quality studies (scores of ≤2/5), primarily narrative or commentary pieces, provided useful context but limited empirical evidence. A full scoring results are presented in the *Results* section (Table 2).

Table . Quality of study assessment.

Authors, country	MMAT[a] score (out of 5)	Comments
Chan and John [18], USA	1	Not an empirical study; and lacks data collection, analysis, or measurable outcomes.
Strauss [19], the Netherlands	4	Strong RCT[b] design, clear measures, and lacks digital delivery and generalizability.
Lou and Arriaga [20], USA	3	Exploratory, appropriate design, and lacks outcome depth and scope.
Teti et al [21], USA	3	Qualitative depth, small sample, and no intervention tested.
Drozdowicz et al [22], USA	4	Well-executed implementation, and lacks ASD[c]-specific data and long-term outcomes.
Pugliese et al [23], USA	4	Feasibility well assessed and pilot scope limits generalization.
Zervogianni et al [24], multicountry	3	Framework development, strong stakeholder input, and lacks effectiveness testing.
Gil-Llario et al [3], Spain	4	Pre-post design, positive results, and small sample and no long-term follow-up.
Chin and Ramachandram [10], Hong Kong	3	Clear pre-post design and lacks control group and large sample.
Ballan and Freyer [11], USA	1	Expert opinion and lacks empirical data.
Shakuri and Alzahrani [25], Saudi Arabia	3	Clear qualitative insights and no intervention tested.
Camilleri et al [26], UK	3	Exploratory design, good engagement data, and lacks outcome rigor.
Panagiotakopoulou et al [27], Greece	3	Focused parent perspective and lacks youth input and intervention.
Quayle et al [28], UK	2	Relevant insights, not ASD specific, and lacks outcome data.
Oğur and Olçay [29], Turkey	3	Clear intervention protocol, small sample, and adult focused.
Wang et al [30], China	3	Important gender-specific insights and lacks adolescent voices and tool testing.

[a]MMAT: Mixed Methods Appraisal Tool.

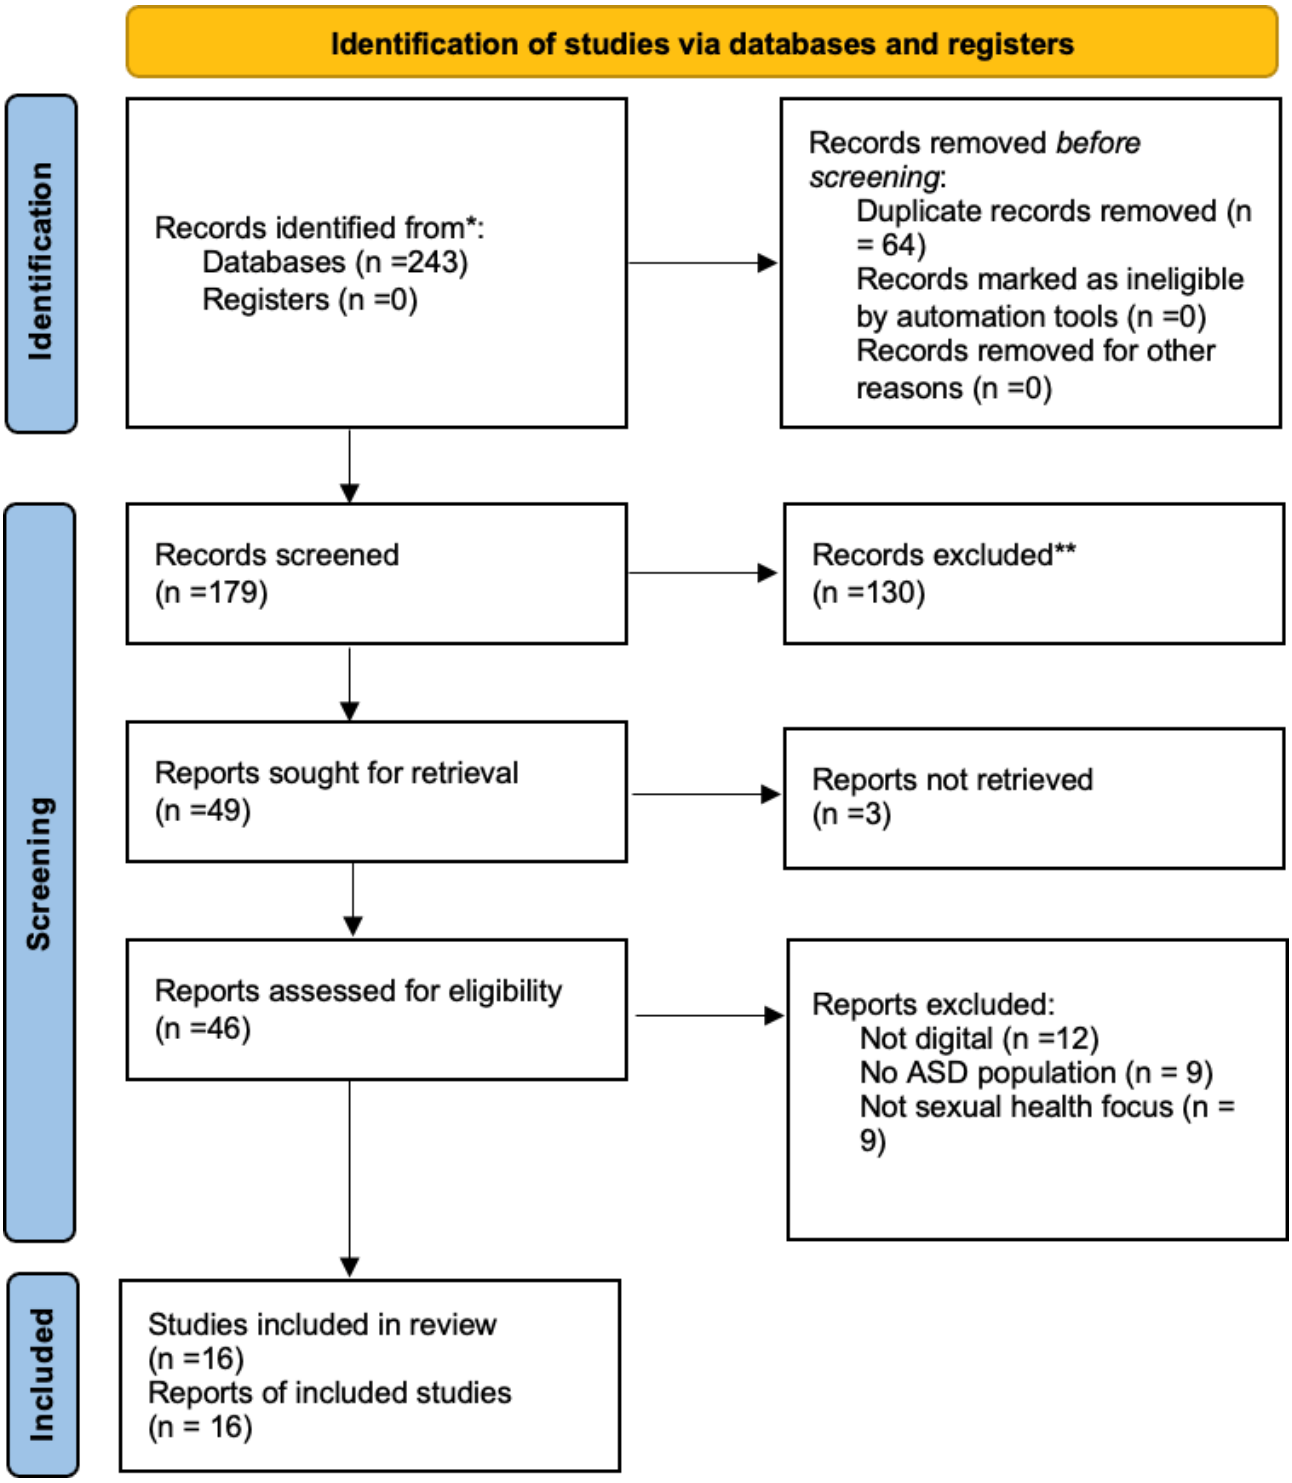
[b]RCT: randomized controlled trial.

[c]ASD: autism spectrum disorder.

XSL•FO
RenderX

Data Analysis and Synthesis

Extracted data were organized into structured summary tables capturing key study features, intervention characteristics, and reported outcomes. A narrative synthesis was then conducted using a combined inductive-deductive thematic approach. Deductive coding was informed by the review objectives and a priori categories, such as digital modality, educational strategies, implementation context, and outcome domains. In parallel, inductive coding allowed new concepts to emerge directly from the data, including participant engagement needs, caregiver involvement, and cultural adaptation factors. Themes were iteratively refined through reviewer discussion to ensure consistency and accuracy. Studies were grouped by platform type (eg, mobile apps, web-based interventions, and interactive video tools) and interpreted alongside their methodological quality to contextualize confidence in the findings. Recurring evidence gaps, such as limited sample diversity, scarce LMIC representation, and a lack of standardized behavioral outcomes or long-term follow-up, were also identified to inform directions for future digital sexual health intervention development.



Results

Searching Result

The PRISMA-ScR flow diagram presents the full screening process. A total of 243 records were identified across databases, with 64 duplicates removed. Following title and abstract screening, 130 records were excluded, leaving 49 full-text articles assessed for eligibility. Three articles could not be retrieved despite attempts to contact authors. Ultimately, 16 studies met the inclusion criteria and were included in this scoping review (Figure 1).

Figure 1. PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) 2020 flow diagram for new scoping reviews, which included searches of databases and registers only. ASD: autism spectrum disorder.

Study Characteristics

All 16 included studies were published between 2012 and 2025. Study designs were diverse, including randomized controlled trials, mixed-methods feasibility studies, qualitative exploratory research, participatory framework development, and case series. Research was conducted in the United States, the United Kingdom, Spain, Turkey, China, Greece, Saudi Arabia, Hong Kong, and multicountry collaborations. Notably, 8 studies directly implemented digital sexual health interventions or closely related digital training, whereas 8 studies explored contextual needs, stakeholder perspectives, theoretical frameworks, or digital adoption challenges without delivering a formal intervention. Studies including broader age groups (eg, young adults) were retained when their findings were directly relevant to adolescent-focused intervention design. Participant groups included autistic adolescents, autistic young adults, parents of autistic youth, clinicians, and digital health practitioners. Reporting of demographic and diagnostic characteristics was highly variable, as summarized in Table 3.

XSL•FO

Table . Characteristics of included studies and summary of findings.

Authors, country	Study design and methodology	Population characteristics	Digital intervention details	Educational content and delivery	Outcomes measured	Key findings and limitations
Chan and John [18], USA	Review with clinical guidance	*No sample and narrative guidance only*	None	Guidance for nurse practitioners on how to discuss sexuality with ASD[a] youth; not a formal intervention	None	Emphasizes early, tailored, and clear communication about sexual health with ASD youth. Not a digital intervention; not a research study
Strauss et al [19], USA	RCT[b]; quantitative, pre-post with control group	Adolescents with ASD, n=96, age 12 - 18 y, mixed gender	Face-to-face psychosexual training (tackling teenage program)	Manualized group sessions on puberty, boundaries, consent, and relationships using visual aids	Knowledge, self-esteem, social functioning, ASD-specific sexual behaviors	Significant improvement; limited by lack of digital tools and generalizability
Lou and Arragia [20], USA	Prototype development and exploratory pilot	Adolescents and young adults with ASD, n=14, age 16 - 21 y	eLIFE social network application	Social support and communication via mobile app	User engagement and perceived usefulness	Feasibility shown, limited sample, and not sexual health specific
Teti et al [21], USA	Qualitative comparative study	Youth with ASD and caregivers, n=10 dyads, youth age 16 - 21 y	No specific tool tested	Need for structured and multimedia sexual education	Themes on miscommunication, autonomy, and relationships	Support for structured education, small sample, and no intervention
Drozdowicz [22], USA	Multisite implementation study using synchronized videoconferencing with standardized patients	Psychiatry trainees and clinical teams, n=42 (not ASD specific)	Educational videoconference sessions involving standardized patient scenarios and delivered synchronously across sites	Sexual health communication training using video-based standardized patient interactions and real-time delivery with feedback	Participant engagement, knowledge gains, comfort in addressing sexual health	Improved comfort and preparedness reported; not ASD specific; no long-term follow-up
Pugliese [23], USA	Pilot feasibility study; mixed methods	Youth with ASD, n=22, age 10 - 17 y; parents involved	Parent-mediated digital materials	Anatomy, consent, communication, and parent led	Knowledge gain and parent-teen interaction	Feasible and acceptable and small pilot scope
Zervogianni et al [24], multicountry	Participatory framework development	Individuals with ASD, n=31, mixed age (including adolescents)	Multiple platforms considered	Co-created framework for digital interventions	Process evaluation and stakeholder satisfaction	Robust framework and no implementation or effectiveness measured
Gil-Llario et al [3], Spain	Quantitative and pre-post design	Youth with ASD, n=27, age 12 - 18 y	Video-based and web-delivered	Anatomy, consent, and boundaries; and interactive videos	Knowledge and acceptability	Improved knowledge, small sample, and no follow-up
Siah [10], Hong Kong	Pilot study and single group pre-post	Youth with ASD, n=18, age 13 - 17 y	Video modeling (3 sessions)	Sexual boundaries, hygiene, and behaviors	Knowledge gain and behavioral understanding	Increased knowledge, no control group, and small sample
Ballan and Freyer [11], USA	Narrative or expert commentary	*No sample; narrative review*	None	Critique of existing nondigital approaches	None	Calls for inclusive digital tools; not empirical
Shakuri and Alzahrani [25], Saudi Arabia	Qualitative study using semistructured interviews with parents	Parents only, n=15, adolescents represented indirectly	No direct intervention and explored digital needs and barriers	Explored parental perceptions of content needs and discussed digital adaptation opportunities	Themes related to cultural, religious, and informational barriers	Strong parental demand for culturally sensitive, digital sexual health resources, and lacks intervention testing
Camilleri [26], UK	Exploratory qualitative study	Autistic youth and parents, n=12, youth age 10 - 18 y	Digital social stories and co-designed	Tailored social-sexual themes	Engagement and parent satisfaction	Improved communication and limited by exploratory scope

XSL•FO
RenderX

Authors, country	Study design and methodology	Population characteristics	Digital intervention details	Educational content and delivery	Outcomes measured	Key findings and limitations
Panagiotakopoulou et al [27], Greece	Qualitative and interviews with parents	Parents of adolescents with ASD, n=14, adolescents indirectly described	No direct intervention	Need for structured and digital tools	Parental perceptions and barriers	Preference for mobile, visual tools, and no youth data
Quayle [28], UK	Qualitative study involving semistructured interviews with child protection and mental health practitioners	Practitioners only, n=20, *not ASD specific*	Discussion of digital health tools (apps, online therapy, AI[c] screening) used or envisioned in abuse prevention services	Focused on service-level integration and digital design for sensitive topics	Perceptions of feasibility, ethical concerns, and implementation barriers	Digital tools viewed as promising but complex to implement and lacking empirical outcome data and ASD focus
Oğur and Olçay [29], Turkey	Case series	Adults with ASD, n=3, age 21 - 23 y, all men	Video BST[d] and digital scenes	Prevention of online sexual abuse	Skill acquisition, competency	Effective training; limited adolescent generalizability
Wang [30], China	Qualitative and interviews with parents	Parents of autistic girls, n=11, age 10 - 17 y	No formal tool	Parental needs for digital sexual education	Unmet needs and preferred formats	Call for visual, gender-sensitive tools and lacks youth voice

[a]ASD: autism spectrum disorder.

[b]RCT: randomized controlled trial.

[c]AI: artificial intelligence.

[d]BST: behavioral skills training.

Digital Intervention Modalities and Implementation

Among the 16 included studies, 8 evaluated digital tools. These interventions primarily used, including interactive video-based sexual education (eg, anatomy, boundaries, and consent), video modeling, and behavioral skills training for online exploitation prevention, mobile and web-based platforms, including social stories and facilitated parental modules, and prototype digital applications supporting psychosexual communication. The remaining 8 studies did not implement a digital intervention but provided essential contextual evidence about acceptability, cultural relevance, and caregiver and professional perspectives that inform digital tool development.

Video-based education was the most frequently used modality. For instance, Gil-Llario et al [3] and Siah et al [10] implemented interactive and modeling-based digital videos to deliver content on consent, boundaries, and appropriate sexual behavior. Similarly, Çimen Oğur and Olçay [29] used video visual scene displays in behavioral skills training to teach online sexual abuse prevention. Pugliese et al [23] and Camilleri et al [26] incorporated parent-mediated modules and co-designed digital social stories, respectively, emphasizing personalized learning.

Mobile and web-based technologies were also explored. Lou and Arriaga [20] tested eLIFE, a prototype social network app aimed at enhancing social communication among youth with ASD, and Zervogianni et al [24] proposed a multiplatform, evidence-based co-design framework for digital tool development. While not always focused specifically on sexual health, these studies revealed key design principles applicable to future interventions. In contrast, several studies [11,27,30] emphasized the need for accessible, culturally responsive, and multimedia sexual health education tools but reported no direct implementation. Parents, in particular, expressed strong preferences for mobile-friendly, visually rich, and repeatable learning formats tailored to the cognitive and developmental profiles of their children.

Educational Content and Delivery Strategies

The digital interventions identified varied in their educational content and delivery strategies. Commonly addressed topics included sexual anatomy, personal hygiene, consent, social boundaries, healthy relationships, and online safety. Interactive video formats and story-based learning were used to model both appropriate and inappropriate behaviors, particularly in studies with youth aged 13 to 18 years. Parent-mediated tools [23] often used structured modules with guided discussions, while other programs [26] emphasized autonomy and co-creation with autistic youth. Despite this diversity, few studies reported the use of established theoretical frameworks, and most lacked standardized instructional approaches, limiting cross-comparability. Duration and frequency of interventions also varied, with only 3 studies clearly reporting session length and instructional pacing.

Outcome Domains and Reported Effects

The most frequently measured outcomes were sexual health knowledge, behavioral understanding, skill acquisition, and acceptability or usability. Quantitative studies such as those by Gil-Llario et al [3] and Siah et al [10] reported significant gains in sexual knowledge postintervention. In Çimen Oğur and Olçay [29], participants demonstrated improved behavioral skills for resisting online exploitation. Pugliese et al [23] reported enhanced parent-child communication, while Camilleri et al [26] noted increased engagement and satisfaction among both youth and parents.

Qualitative studies underscored the emotional, relational, and cognitive barriers that youth with ASD face regarding sexuality.

XSL•FO
RenderX

Teti et al [21] and Wang et al [30] highlighted themes of communication breakdown, information gaps, and parental uncertainty, while Lou and Arriaga [20] emphasized the socioemotional impact of peer-based digital tools. However, many of these studies did not measure outcomes longitudinally, limiting insight into sustained effectiveness.

Methodological Limitations and Evidence Gaps

Across studies, common limitations included small samples, absence of control groups or randomization, nonstandardized outcomes, and short follow-up periods. Three recurrent evidence gaps were reported: (1) limited participatory co-design with autistic adolescents, (2) underrepresentation of female participants and lack of gender-specific content, and (3) few implementations in LMICs. These gaps were noted but not tested as effect modifiers. Only Wang et al [30] addressed female-specific educational gaps, emphasizing the lack of tailored content. Co-design with autistic adolescents was inconsistently applied, although Zervogianni et al [24] and Camilleri et al [26] provided important examples of participatory development.

Thematic Patterns

The narrative synthesis revealed several recurring patterns across the included studies. One prominent theme was the need for personalization and visual interactivity within digital sexual health interventions designed for adolescents with ASD. Interventions that used video modeling, interactive storytelling, or visual scene displays were notably more effective in enhancing comprehension and engagement, particularly among youth with ASD, who often benefit from visual structure and concrete representations of social behavior [10,26,29].

Another consistent finding was the strong demand from caregivers for mobile-accessible, culturally sensitive, and repeatable educational content. Parents expressed a clear preference for digital tools that could be used flexibly within the home, reflect local sociocultural values, and offer structured, developmentally appropriate guidance on sexual health topics [23,27,30].

A third thematic pattern highlighted critical gaps in the implementation and evaluation of digital interventions. Many studies lacked contextual diversity, with limited representation of LMICs, and often failed to incorporate adolescent end users in the design process [11,24]. Inadequate attention to co-design and cultural adaptability may reduce the acceptability and effectiveness of digital interventions across different settings. Moreover, few studies included long-term follow-up or robust behavioral outcome measures, limiting the ability to assess sustained impact [3,20].

Methodological Quality Appraisal

The overall methodological quality of the included studies varied. High-quality studies, such as those by Strauss et al [19], Drozdowicz et al [22], Pugliese et al [23], and Gil-Llario et al [3], scored 4/5 on Mixed Methods Appraisal Tool, reflecting strong designs with clear outcomes, although some lacked digital focus or generalizability. Moderate-quality studies (3/5), including Lou and Arriaga [20], Teti et al [21], and Siah et al [10], showed feasibility or insight but were limited by sample size or lack of control groups. Lower scores (≤2/5), such as Chan and John [18] and Ballan and Freyer [11], were nonempirical or lacked data collection, limiting their evidentiary value (Table 2).

Discussion

Principal Findings

This scoping review maps the emerging landscape of digital sexual health education for adolescents with ASD. Across diverse study designs and settings, the evidence indicates early effectiveness for formats that align with ASD learning characteristics, particularly visually rich, structured, and repeatable content, while also revealing systemic gaps that limit generalizability and equity. Below, we interpret key patterns and translate them into actionable implications for design, implementation, and evaluation.

Expanding upon foundational reviews by Pownall et al [31] and Dewinter et al [32], which underscored the scarcity of structured, inclusive sex education for neurodiverse individuals, this review uniquely updates the evidence base with a focus on digital modalities. Previous syntheses primarily emphasized content deficits and the inadequacy of traditional education formats for autistic learners. In contrast, our findings highlight a tangible shift toward digital, video-based, and mobile platforms that are more aligned with the cognitive, sensory, and social processing styles of autistic adolescents. This shift marks a substantial evolution in approach, emphasizing not only what is taught, but how and by whom it is delivered. Unlike earlier reviews that often conflated multiple developmental disabilities, this scoping review centers specifically on ASD, revealing critical insights into learning preferences, gender disparities, and digital engagement unique to this population. A notable distinction is the emerging but still limited incorporation of co-production and participatory design, reflecting a movement toward user-centered innovation in health education. This is particularly significant, given the evidence that autistic individuals benefit from interventions designed with their direct input [24].

A central theme across the reviewed literature is the demonstrated effectiveness of video-based interventions in enhancing sexual knowledge and social comprehension. Studies by Gil-Llario et al [3], Siah et al [10], and Çimen Oğur and Olçay [29] illustrate that interactive video, especially those incorporating role modeling, repetition, and guided narration, can support autistic adolescents in understanding abstract concepts, such as consent, bodily autonomy, and relationship boundaries. These pedagogical strategies are fundamentally aligned with the cognitive characteristics of ASD [26], including a preference for visual, concrete, structured learning, reduced social inference skills, and challenges in generalization across contexts. Therefore, future digital interventions should increasingly incorporate visual prompts, stepwise sequencing, clearer discrimination between appropriate and inappropriate behaviors, and opportunities for individualized feedback and repeated practice.

XSL•FO
RenderX

Another critical finding emerging from the reviewed studies is the central role of caregivers in facilitating sexual health learning among autistic adolescents. Evidence from Pugliese et al [23] and Panagiotakopoulou et al [27] shows that parents overwhelmingly favor visually rich, repeatable, and culturally adaptable content—particularly in contexts where formal sex education is limited or inconsistently delivered to neurodiverse youth. These preferences reflect the widespread reliance on the family as a primary learning environment and suggest that digital tools are more likely to be used when they can be integrated into existing home routines and communication patterns.

Despite these promising developments, the body of evidence remains fragmented and unevenly distributed. Most studies originate from high-income settings, with limited consideration for sociocultural values, digital access, and educational policies in LMICs. This geographic concentration reduces the transferability of findings to resource-constrained settings, where formal sexuality education may be stigmatized or absent. The lack of reporting on cultural or religious context in intervention design also limits understanding of how well existing programs align with local expectations regarding sexual behavior and autonomy. Across studies, intervention samples frequently overrepresented male adolescents, meaning that the needs, experiences, and risks faced by autistic girls remain insufficiently represented. Only a small number of studies, such as Wang et al [30], explicitly examined female perspectives in digital development or outcome reporting. This gender imbalance reflects a broader trend in autism research and raises concerns that current interventions may unintentionally reinforce a male-centric understanding of autistic sexuality.

Taken together, these findings indicate that while digital interventions hold considerable promise in tailoring sexual health education to autistic adolescents' learning profiles, important equity considerations persist. Variability in sampling, design rigor, cultural contextualization, and gender representation highlights the need for continued refinement before such interventions can be confidently translated into routine education and clinical practice. Strengthening methodological quality and ensuring inclusive design processes will be essential to develop interventions that are not only effective but also broadly relevant and accessible.

Importantly, the underrepresentation of female adolescents with ASD has long been recognized as a systemic gap in autism research and persists. Only a handful of studies, such as Wang et al [30], explored the unique needs and experiences of girls, raising concerns about gender equity in intervention design and delivery. Without targeted inclusion, current tools risk reinforcing a male-centric view of autism that excludes a significant portion of the population. Geographic and socioeconomic disparities also limit the generalizability of current findings. Very few studies examined implementation in LMICs, where digital infrastructure, cultural norms, and access to health education differ markedly from high-income contexts. As Ballan and Freyer [11] argue, failing to address these structural factors risks exacerbating existing inequities, particularly for youth in marginalized communities. Future tools must therefore ensure gender-responsive adaptation of content, particularly around puberty, menstrual health, privacy, and romantic relationships.

Collectively, these findings affirm that digital interventions hold transformative potential for delivering inclusive, accessible, and developmentally appropriate sexual health education to adolescents with ASD. However, a shift from proof-of-concept studies to large-scale, context-sensitive, equity-driven research is urgently required. This includes participatory design methods that meaningfully involve autistic adolescents, families, and educators in LMICs to ensure interventions are relevant, feasible, and ethically grounded.

Limitations

This scoping review has several limitations that should be considered when interpreting the findings. First, significant methodological heterogeneity across the included studies, particularly in sample sizes, designs, and outcomes, restricted the ability to compare results directly or assess effectiveness at scale. Second, limiting the search to English-language publications may have led to the exclusion of relevant evidence from non-English-speaking regions, potentially underrepresenting interventions developed in culturally diverse contexts. Third, most studies were conducted in high-income countries, which limits the generalizability of findings to low- and middle-income settings where resources, digital access, and sociocultural norms related to sexuality education differ markedly. Fourth, although a methodological quality appraisal was conducted, many studies provided only preliminary or feasibility data, making it difficult to draw strong conclusions about long-term behavioral impact. Finally, rapid technological evolution means that some digital tools reviewed may already be outdated, affecting the current applicability of results. Collectively, these limitations emphasize the need for more rigorous, inclusive, and globally representative evaluations to strengthen the evidence base for digital sexual health education among autistic adolescents.

Implications for Nursing Practice

This review underscores the essential role of nurses in facilitating and advocating for digital sexual health education for autistic adolescents. To ensure interventions are effective and sensitive to ASD-specific learning needs, nurses require competencies in both sexual health communication and digital literacy. As caregivers often serve as primary educators on sexuality, nursing support should extend to families by offering structured guidance and training in the confident and appropriate use of digital tools. In addition to direct education, nurses act as key advocates in shaping school and community policies that promote equitable digital access, safeguard privacy, and ensure culturally and linguistically responsive resources, particularly in LMICs where stigma and limited services remain major barriers to sexual health education.

Future research and program development should prioritize participatory co-design involving autistic adolescents, ensure more gender-responsive content that better represents girls, and adopt standardized outcomes with longitudinal or controlled designs to improve evidence strength and real-world applicability. Emerging approaches such as gamification and

XSL•FO
RenderX

artificial intelligence–driven personalization hold promise for enhancing engagement and adaptive learning. Through continued leadership in policy, practice, and interdisciplinary collaboration, nurses will play a critical role in ensuring digital interventions are ethical, accessible, and inclusive, ultimately empowering autistic adolescents to build autonomy, agency, and personal safety in their relationships and sexual health.

Conclusions

Digital health interventions show considerable promise in closing the longstanding gap in sexual health education for adolescents with ASD, particularly when designed to reflect their visual, structured, and self-paced learning needs. Current evidence demonstrates early effectiveness but remains limited by small samples, inconsistent measurement, and underrepresentation of girls and youth from low-resource settings. Moving forward, progress depends on participatory co-design with autistic adolescents, gender-responsive content, and culturally adaptable formats suitable for LMICs. Strengthening methodological rigor through standardized outcomes and longer follow-up will be essential to understanding long-term impact. Ultimately, digitally enabled, inclusive sexual health education can equip autistic adolescents with the autonomy, safety skills, and confidence needed to navigate relationships and well-being throughout their lives.

Abstract

Background: Virtual reality (VR) technology offers a new approach for the intervention of social communication skills in children with autism spectrum disorder (ASD), but the comparative effects of different forms of VR technology remain unclear.

Objective: This study aims to conduct a systematic review and network meta-analysis (NMA) based on existing randomized controlled trials (RCTs) to initially explore and compare the effects of different VR technologies on improving the social and communication skills of children with ASD.

Methods: We systematically searched relevant RCTs in both Chinese and English databases from January 1990 to February 2025. The quality of the literature was evaluated using the revised Cochrane risk of bias assessment tool (RoB-2), and an NMA was conducted under the frequentist framework using STATA 18.0 software. The quality of evidence was assessed using the Confidence in Network Meta-Analysis framework.

Result: A total of 11 RCTs (718 children) were included, evaluating 8 VR technologies. The evidence network was extremely sparse, with most interventions connected by single studies. Pairwise meta-analysis revealed overwhelming heterogeneity (I^2=91.9%, P<.001), indicating profound clinical and methodological diversity. Due to this heterogeneity and the sparse network, the NMA model failed to produce stable or clinically interpretable effect estimates. Formal assessment using the Confidence in Network Meta-Analysis framework rated the confidence in all comparisons as very low.

Conclusions: The existing evidence is insufficient to support any comparative efficacy conclusions or rankings among VR technologies for ASD social skills. The key finding is the demonstration that current evidence is too heterogeneous and immature for valid quantitative synthesis. Future research must prioritize methodological standardization before head-to-head trials can be meaningfully conducted.

KEYWORDS

autism spectrum disorder; virtual reality; social communication skills; network meta-analysis; children

Introduction

Autism spectrum disorder (ASD), commonly referred to as autism, is a neurodevelopmental disorder that originates in early childhood. Its primary characteristics include impairments in social interaction and communication, repetitive patterns of behavior, and restricted interests or activities [1]. The global prevalence of autism is on the rise [2]. According to the 2023 report from the US Centers for Disease Control and Prevention, by 2020, the prevalence of ASD among 8-year-old children was

XSL•FO
RenderX

approximately 1 in 36 (4% for boys and 1% for girls), which is higher than the estimation of the Autism and Developmental Disabilities Monitoring network from 2000 to 2018 [3]. A multistage convenience cluster sampling study in China indicates that the estimated prevalence of ASD among children aged 6 to 12 years in China is 0.70%, equivalent to approximately 700,000 children [4]. One of the core symptoms of ASD is social impairment, which manifests as a lack of early social interest and motivation compared to peers, ultimately affecting their ability to engage socially [5]. Even when they exhibit social interest, they often lack the necessary social skills for appropriate interaction with others [6]. This leads to difficulties in effectively communicating and interacting with others, hindering their ability to maintain normal social relationships, which further impacts their language skills and mental health [7]. Therefore, it is essential to identify effective and sustainable measures to enhance social and communication skills among individuals with ASD.

Although current medical research has made certain progress, the exact cause of the disease has not been fully clarified. Existing studies suggest that the disorder may be caused by the interaction of multiple factors, such as genetic susceptibility [8], environmental exposure [9], and abnormal changes in the neurodevelopmental process. Due to the complexity of its pathogenesis, there is currently no specific treatment strategy targeting the cause [10]. Currently, clinical practice primarily employs comprehensive treatment, encompassing drug therapy, behavioral modification, educational training, and physical therapy [11,12]. However, traditional treatments still have some limitations. For example, behavioral training relies heavily on the therapeutic room environment and lacks ecological validity in real-world social scenarios, making it difficult to transfer skills [13]. Second-generation antipsychotic drugs (such as risperidone) can alleviate aggressive behavior but cannot improve core symptoms and carry the risk of metabolic syndrome [14]. In addition, autism is characterized by a high disability rate and currently lacks an effective cure. Its management primarily involves long-term, intensive professional rehabilitation interventions aimed at enhancing the overall abilities of children with autism. Nevertheless, these interventions impose significant economic burdens, demand substantial time commitments from caregivers, and exert considerable psychological pressure [15]. Moreover, they present formidable challenges for the allocation of social public resources, the establishment of professional service systems, and ensuring their long-term sustainability.

Since the 1990s, numerous empirical studies have systematically explored the feasibility and effectiveness of utilizing virtual reality (VR) for training and intervention in individuals with ASD [16]. VR technology is capable of integrating the real and virtual worlds, replicating diverse scenarios via algorithms, generating immersive experiences, and enabling human-computer interaction through controllers, thereby embodying the characteristics of immersion, interactivity, and imagination [17]. Over the past 2 decades, VR has been extensively applied in medicine and has garnered increasing attention in clinical cognitive rehabilitation [18]. Relevant research indicates that VR not only enhances the life skills of individuals with ASD [19], but also improves their cognitive abilities [20], emotional regulation and recognition skills [21], as well as social and communication competencies [22]. Studies demonstrate that VR technology exhibits unique advantages in addressing core symptoms in children with ASD through mechanisms, such as neuroplastic remodeling, behavioral reinforcement learning, and multimodal compensation [23].

Current VR intervention studies encompass desktop-based, augmented reality, immersive, and hybrid technologies [24], with intervention content spanning areas, such as social communication and emotional cognition [25]. However, the evidence base is characterized by profound heterogeneity in intervention protocols, outcome measurement instruments, and participant characteristics. Moreover, head-to-head comparisons between different VR modalities are virtually absent, and the existing studies primarily compare each active intervention against heterogeneous control conditions. This fragmented evidence landscape renders conventional pairwise meta-analysis insufficient for comparative efficacy questions, but it also raises fundamental concerns about whether the more complex network meta-analysis (NMA) can be validly applied.

While NMA offers a theoretical framework to integrate direct and indirect evidence and derive comparative effect estimates even when head-to-head trials are lacking, its validity critically depends on the assumptions of transitivity and consistency. Given the anticipated clinical and methodological diversity among studies in this nascent field, these assumptions are likely to be violated.

Therefore, we aim to (1) systematically map the existing randomized controlled trial (RCT) evidence on VR interventions for social and communication skills in children with ASD; (2) formally assess whether the current evidence base satisfies the assumptions required for a valid NMA; (3) assess if these assumptions are seriously violated, to conduct a detailed methodological “autopsy” to characterize the sources and magnitude of heterogeneity, network sparsity, and evidence gaps; and (4) derive concrete, prioritized recommendations for future research that address the identified methodological barriers. By reframing the analysis from hypothesis verification to hypothesis generation and from comparative efficacy assessment to evidence readiness assessment, this study aims to provide a rigorous foundation for the design of future comparative effectiveness trials and for the eventual translation of VR technologies into clinical practice.

Methods

This systematic review was conducted in accordance with the PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) and the PRISMA extension of the NMA guidelines [26], the details of which can be found in Checklist 1. This study is registered in the PROSPERO (International Prospective Register of Systematic Reviews) international systematic evaluation platform (CRD420250654696).

Search Strategy and Inclusion and Exclusion Criteria

The selection and search strategies for eligible studies were constructed based on the PICOS (population/patient,

XSL•FO
RenderX

intervention, comparator, outcome, and study design) framework. We systematically retrieved data from 8 electronic databases (PubMed, Embase, Cochrane Library, Web of Science, EBSCOhost, CNKI, VIP, and Wanfang) from 1990 to February 26, 2025. To ensure no eligible literature was overlooked, we also examined the reference lists of earlier systematic reviews [23,27-30] and the included studies as supplementary sources. Due to the limitations of obtaining professional resources, only literature published in both Chinese and English was included in this search. The detailed search strategy is introduced in Multimedia Appendix 1. Following a thorough search of numerous databases, duplicate publications were discarded. Titles and abstracts were then screened, and full texts were assessed according to the inclusion and exclusion criteria. The screening and selection processes were independently conducted by 2 evaluators (L.W and XG). Any differences are determined through consultation by a third evaluator (XB).

Table 1 displays the specific selection criteria. Overall, if a study meets the following conditions, it is considered to be eligible: (1) the trial design is an RCT aiming to evaluate the effectiveness of any VR intervention on children with autism; (2) recruitment of children diagnosed with ASD is based on clinical assessments or the criteria from the *DSM-5* (*Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition*) or other recognized diagnostic standards (such as the *Autism Diagnostic Observation Schedule, 2nd Edition* or the *International Classification of Diseases, 10th Edition*); (3) participants in the control group underwent non-VR interventions, nondrug treatments, or routine nursing care, whereas those in the experimental group were exposed to VR interventions; and (4) at least 1 outcome related to social or communication function is reported in the outcome indicators. Studies will be excluded if they (1) are republished articles; (2) cannot provide the full text or have a high risk of bias (such as an unrigorous trial design, lack of participant data, etc); or (3) are reviews, observational studies, case reports, letters to the editor, or conference abstracts.

Table . PICOS (population/patient, intervention, comparator, outcome, and study design) criteria for inclusion of studies.

Parameter	Criteria
Population	Children and adolescents under 18 years of age and were diagnosed with ASD[a]
Intervention	Research involving any type of virtual reality intervention
Comparator	No limitations on the control group except virtual reality interventions, such as no-treatment, waiting-list control, traditional care, or cannot be included in other treatment nodes
Outcomes	Any outcomes regarding social and communication skills that can be measured
Study design	Randomized controlled trials

[a]ASD: autism spectrum disorder.

Outcome

The primary outcome was social and communication skills. The efficacy was expressed as the change in the overall social and communication symptom assessment score after the VR intervention (data collected before and after the intervention).

Data Extraction

Two independent reviewers (XG and SL) extracted relevant information in a standard manner, including bibliographic data (author, publication year, and country/region), participant characteristics (age, gender, and sample size), intervention components (category, frequency, and duration), and immediate postintervention primary outcome measures. In cases where studies used 2 or more measurements for the same outcome indicator, the task most commonly utilized was included. If a single task had multiple raw scores, higher-quality results were preferred. The formula from the Cochrane Handbook was used to calculate the changes in mean and SD relative to the baseline when they were not fully reported [31]. We reached out to the corresponding author via email to gather more information if any data were missing. The Cochrane risk of bias tool for randomized trials [32] was used to assess the methodological quality of the included RCTs. The evidence quality of social and communication abilities was evaluated within the framework of CINeMA (Confidence in Network Meta-Analysis) [33].

For the purpose of this NMA, interventions were grouped based on their primary technological interface as reported in the original studies. Given the significant variation in specific hardware, software, and intervention protocols even within the same broad category and the diversity of control conditions, we explicitly acknowledge that these operational groups may encompass substantial clinical and methodological heterogeneity. This heterogeneity is a critical consideration when interpreting the transitivity assumption of the NMA and the pooled results, as discussed in the *Limitations* section.

Data Analysis

The data analysis was conducted jointly by 2 researchers (LW and DL). Given the significant clinical and methodological differences among the included studies in terms of population characteristics, intervention protocols, outcome measures, and the sparse preliminary evidence network, this study adopts a hierarchical analysis strategy. First, we will conduct a detailed descriptive synthesis, systematically presenting and comparing the key features and main findings of each study. Subsequently, we will perform an exploratory NMA to visualize the evidence structure and generate preliminary, hypothetical comparative

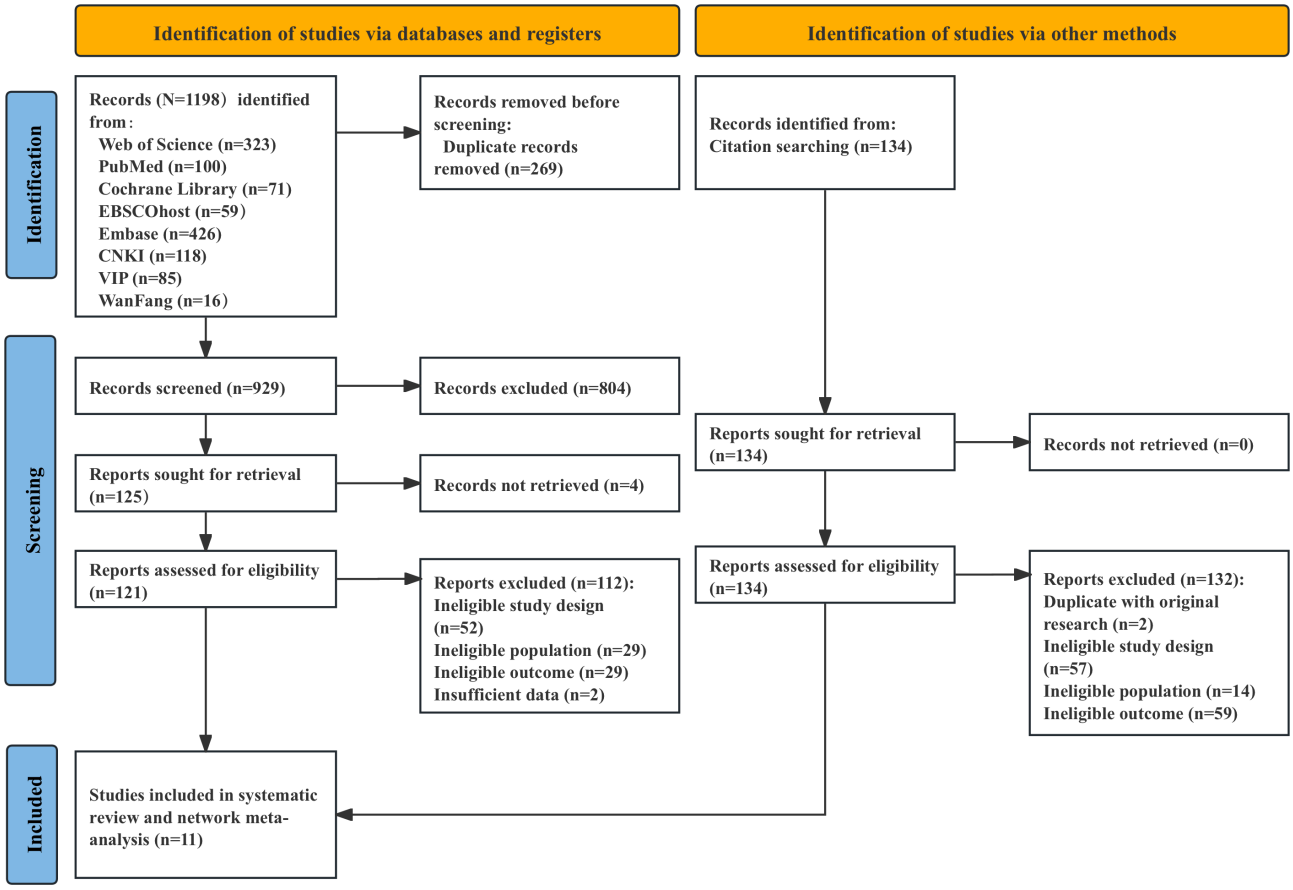
XSL•FO
RenderX

results. It must be emphasized that due to the aforementioned limitations, the point estimates and ranking results of the NMA have high uncertainty and should be regarded as a hint for future research directions rather than definitive efficacy conclusions or clinical recommendation bases.

All data analyses were performed using STATA 18.0 (StataCorp LLC) software, following the protocol outlined below.

All outcomes were continuous variables. To mitigate baseline discrepancies, effect sizes were pooled using changes in mean values and SDs before and after the intervention. Given the variability in assessment tools and units across studies, standardized mean differences (SMDs) were adopted as the effect metric. First, traditional pairwise meta-analyses were conducted using the "metan" command to compute pooled SMDs and their 95% CIs for all comparisons between VR interventions and usual care, with forest plots generated for visualization. A random-effects model was employed to account for between-study heterogeneity, which was quantified using the I^2 statistic: $I^2 \leq 50\%$ indicated low heterogeneity, whereas $I^2 > 50\%$ denoted high heterogeneity. Transitivity was evaluated by comparing the distribution of study characteristics across intervention comparison pairs—specifically, examining whether characteristics were balanced across all intervention pairs connected via a common comparator. Systematic differences in characteristic distributions would suggest the potential violation of the transitivity assumption. We compared the distribution of key covariates that might affect the treatment effect between the groups in direct comparison and found no obvious systematic imbalance. This provides a preliminary basis for transitivity in the network analysis. However, due to the limited number of studies, the assessment of this assumption still needs to be cautious. In fact, given the observed clinical diversity in participants, interventions, and outcomes across studies, we anticipated potential violations of these assumptions. Therefore, all NMA results are presented as exploratory estimates, and the ranking of interventions is interpreted with caution, emphasizing the generation of hypotheses for future research rather than definitive clinical conclusions.

Building on descriptive analyses, exploratory NMA was conducted. Evidence networks were visualized using the "network" command to illustrate direct and indirect comparisons among distinct VR technologies. For closed loops within the network, node-splitting was performed to test for consistency; in cases of inconsistency, an inconsistency model was applied [34]. The analysis model was fitted using the "mvmeta" command under a frequentist framework, which allows sharing of a common heterogeneity parameter across comparisons. The surface under the cumulative ranking curve was calculated using the "sucra" command to generate preliminary rankings of interventions [35]. League tables summarizing SMDs and 95% CIs for all pairwise intervention comparisons were produced using the "netleague" command. Funnel plots were generated via the "metafunnel" command, and the Egger test (implemented via the "metabias" command) was used to quantitatively assess small-study effects [36]. Leave-one-out sensitivity analysis was conducted using the "metaninf" command to evaluate the stability of pooled effect sizes by sequentially excluding each study. To explore potential sources of heterogeneity, subgroup analyses were performed based on predefined factors (eg, intervention modality, geographic region, and intervention duration). Additionally, meta-regression was conducted using the "metareg" command to examine the association between continuous variables (eg, sample size and total intervention length) and effect sizes. All analyses were conducted using a 2-tailed test, with the significance level α set at 0.05.



Results

Summary of Results

The retrieval of the system identified 1198 records from the electronic database. Once duplicates were eliminated, the titles and summaries of the bar records were reviewed, and 125 full-text articles were obtained to assess their eligibility. Another 134 records determined from the reference list of the relevant systematic review were also screened as qualified. The method used for literature screening is presented in Figure 1. Finally, a total of 11 studies [37-47] were included in this review, involving 718 children with ASD.

XSL•FO
RenderX

Figure 1. PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) flowchart of study selection.

However, the preliminary synthesis of direct comparison evidence revealed extremely high heterogeneity among the studies (I^2=91.9%, P<.001). This result suggests that there are fundamental differences in intervention protocols, participant characteristics, and outcome measurement tools among the various studies, which make the traditional combined effect size insufficiently robust and clinically meaningful when interpreting the overall efficacy. Therefore, the following analysis will focus on describing the current state of evidence and exploratory findings.

Research Characteristics

Table 2 summarizes the details of each included study. Among the 11 studies, all employed recognized diagnostic criteria for participant identification. The age of participants ranged from preschoolers to adolescents. The experimental interventions comprised 8 distinct forms of virtual technology, classified as digital platform, head-mounted display (HMD), VR glasses, mixed reality, CAVE (cave automatic virtual environment), Half-CAVE, desktop VR, and computer-based magic skill training. HMD was the most frequently evaluated technology (n=3), followed by digital platforms. Control conditions varied and included conventional rehabilitation care, wait-list controls, or other active non-VR therapies.

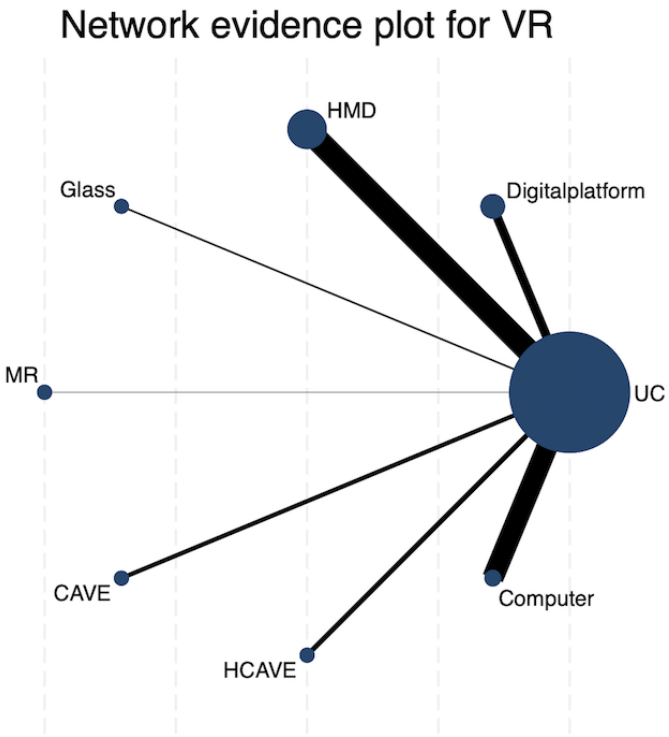
[x]SSIS: Social Skills Improvement System.

Notably, there was substantial diversity in the intervention protocols. Even within the same technology category, the specific content of virtual scenarios, interaction modalities, session duration, intervention frequency, and total intervention period differed markedly across studies. This indicates that each study investigated a unique “intervention package” rather than a standardized application of a given technology.



Evidence Network and Assessment of Heterogeneity

Figure 2 presents the geometry of the treatment network for the primary outcome. The network is sparse and unbalanced. While

XSL•FO
RenderX

several direct comparisons exist between HMD and conventional care (forming the backbone of the network), many other intervention nodes are connected by only a single study. A large number of potential comparisons between different active VR technologies lack direct evidence and must rely entirely on indirect estimations. This sparsity fundamentally limits the stability and reliability of any quantitative comparative estimates derived from the network.

Figure 2. Network of eligible comparisons for the primary outcome (social and communication skills). CAVE: cave automatic virtual environment; H-CAVE: half cave automatic virtual environment; HMD: head-mounted display; MR: mixed reality; VR: virtual reality.

The preliminary pairwise meta-analysis of all VR interventions versus control groups revealed an exceptionally high degree of statistical heterogeneity (I^2=91.9%, P<.001). This overwhelming heterogeneity is not merely statistical but reflects profound clinical and methodological diversity across studies in terms of participant profiles, the nature and intensity of VR interventions, and—most critically—the tools used to measure social and communication skills. These tools assess different constructs and dimensions of social functioning with varying sensitivity. Consequently, the traditional pooled effect size, while indicative of a general positive direction, is too heterogeneous to be meaningfully interpreted as a single, precise estimate of efficacy.

Exploratory Quantitative Synthesis Findings

Given the severe and anticipated violations of the NMA assumptions—demonstrated by the extreme statistical heterogeneity (I^2=91.9%, P<.001) and the sparse, disconnected evidence network—any quantitative synthesis must be interpreted with the highest degree of caution.

Under a frequentist random-effects framework, the model produced comparative effect estimates for all contrasts; however, the 95% CIs were implausibly wide, and the model failed to achieve stable convergence. The leave-one-out sensitivity analysis confirmed that no single study was responsible for these extreme outputs; rather, the instability is an intrinsic mathematical consequence of synthesizing highly heterogeneous studies within an inadequately connected network. The formal assessment of the confidence in the evidence using the CINeMA framework rated all comparisons as “very low,” driven by serious concerns regarding within-study bias, intransitivity, imprecision, and network sparsity (see Multimedia Appendix 1).

Consequently, we do not report any specific SMDs, CIs, or surface under the cumulative ranking curve values in this section. These unstable numerical outputs are provided in Multimedia Appendix 1 for transparency and reproducibility purposes only. They must not be cited, interpreted, or used to infer the comparative efficacy or rank order of the included VR technologies. The sole robust quantitative finding from this analysis is the I^2 statistic of 91.9%, which unequivocally demonstrates that the included studies are too clinically and methodologically diverse to be meaningfully combined for the purpose of comparative effect estimation.

Risk of Bias and Quality of Evidence

We used the revised Cochrane risk of bias tool (RoB-2) to assess the included studies, and the results are detailed in Multimedia Appendix 1. The overall risk of bias was judged as moderate. The analysis revealed a distinct pattern: the most prominent sources of bias pertained to the randomization process and deviations from intended interventions. In these domains, a notable proportion of studies were rated as “high risk,” accompanied by a substantial number with “some concerns,” marking them as the core contributors to the overall risk of bias.

XSL•FO
RenderX

The selection of the reported result emerged as a prevalent area of potential bias; while fewer studies were "high risk" in this domain, the majority raised "some concerns," indicating a widespread methodological limitation. In contrast, risks in the domains of measurement of the outcome and missing outcome data were relatively lower, with assessments predominantly being "low risk" and only sporadically "some concerns," suggesting these aspects were better controlled.

Furthermore, we used the CINeMA framework to rate the confidence in the NMA evidence of social and communication skills, which was very low in all comparisons. The results are detailed in Multimedia Appendix 1. This rating was driven by serious concerns about within-study bias (moderate risk of bias in included trials), nontransitivity (clinical and methodological heterogeneity), imprecision (very wide CIs), and sparse data (a small number of studies forming the network). This very low confidence rating formally emphasizes the high uncertainty of the quantitative estimates and rankings.

Other Exploratory Analyses

Meta-regression did not indicate the significant effects of region, intervention form, intervention duration, and intervention cycle on social and communication skills. Meanwhile, the subgroup analysis showed significant heterogeneity among different regions and different intervention form groups. The research results are presented in Multimedia Appendix 1. The source of this heterogeneity might be due to the insufficient sample size of the included original studies. Furthermore, in a single intervention, a treatment course of more than 40 minutes showed significant heterogeneity, which might be attributed to methodological differences, individual differences among participants, publication bias, among other factors. In Multimedia Appendix 1, the sensitivity analysis demonstrated that excluding studies with a high risk of bias generally yielded results consistent with the original findings. The funnel plot in Multimedia Appendix 1 shows that the scattered points are mainly located at the top of the funnel and demonstrated bilateral symmetry, indicating that the studies using the Social Functioning Assessment Scale as the outcome measurement have the least publication bias. However, 3 studies were located outside the funnel and were rather scattered, indicating that there might be a certain degree of publication bias, which could be due to the small sample size and low accuracy.

Discussion

Key Findings

This is the first study to apply the NMA to compare VR technologies for social skills in children with ASD. The most salient finding, however, is not a comparative effect estimate or ranking but rather a negative one: the existing evidence base is too heterogeneous, sparse, and methodologically inconsistent to support any valid quantitative synthesis. The critical findings are not comparative effect sizes or intervention rankings but rather (1) extreme and irreducible statistical heterogeneity (I^2=91.9%, P<.001), reflecting profound clinical and methodological diversity; (2) a sparse and disconnected evidence network in which most intervention nodes are supported by single studies and the majority of pairwise comparisons lack any direct evidence; (3) clear violations of the transitivity and consistency assumptions required for a meaningful NMA; and (4) "very low" confidence in all comparative estimates as rated by the CINeMA framework. In essence, the attempt to perform an NMA "failed"—and this failure is itself the most robust and clinically informative result of this study. Therefore, this discussion will first critically examine these limitations and then, within the framework of the existing evidence, cautiously explore the potential value and challenges of different VR technologies and point out directions for future research.

Why Did the NMA Fail? Limitations and Sources of Heterogeneity in the Existing Evidence

Although the NMA provides a theoretical framework for comparing multiple interventions, the reliability of its results depends on the internal consistency of the evidence base [48]. The extreme heterogeneity observed in this study (I^2=91.9%) is not accidental but stems from fundamental, irreconcilable differences at multiple levels that directly violate the transitivity and consistency assumptions of NMA.

First, in terms of outcome measurement tools, various studies employed a range of tools, such as from the Autism Behavior Checklist and Psychoeducational Profile to the Vineland Adaptive Behavior Scales, each assessing social functions in different dimensions, with varying degrees of sensitivity and scoring methods. The direct combination of their data assumes conceptual equivalence that does not hold, and this alone renders any pooled effect size uninterpretable [49]. Second, in terms of intervention protocols, even within the category of "head-mounted displays," there are significant differences in core elements, such as the specific content of virtual scenarios, interaction logic, duration of each session, total intervention period, and whether therapist guidance is included, making them essentially different "intervention packages." Third, in terms of study subjects, key characteristics, such as the age range of children, severity of ASD, and cognitive function levels, vary. These clinical and methodological diversities make it difficult to directly compare the study results and are the main reasons for the wide range of effect sizes observed. These clinical and methodological diversities are not merely nuisances to be statistically adjusted; they represent fundamental violations of the assumption that studies are sufficiently similar to be synthesized for comparative inference. Consequently, the primary robust conclusion from this quantitative exercise is the profound inability of the existing data to support stable or credible comparative effect estimates using the NMA.

The Potential Value and Implementation Considerations of Different VR Technologies

While acknowledging the aforementioned limitations, a descriptive synthesis of existing research can still offer valuable insights. Various forms of VR technologies, including HMDs, desktop VR, and augmented reality, have all reported positive improvements in social skills in their respective studies [50]. Among them, HMDs have shown outstanding potential in multiple studies due to their ability to provide highly immersive, controllable, and customizable virtual social environments [51]. This sense of immersion may help attract the attention of children with ASD and allow them to practice social interactions

XSL•FO
RenderX

in a safe and highly repetitive environment, which aligns with the views presented in the systematic review by Bradley and Newbutt [52]. However, this does not imply that HMDs are superior to other modalities; they are simply the most intensively studied to date. For instance, desktop VR, with its lower sensory load and higher operational convenience, may be more suitable for some sensitive individuals or as an initial adaptation tool [53]. Meanwhile, CAVE systems, despite being limited to fixed locations, offer a unique shared space experience and are suitable for group training that requires close guidance from therapists [23].

At the same time, we must confront the practical challenges that VR intervention, especially immersive devices, faces in clinical translation. Although initial data suggest that children with ASD have a good acceptance of HMDs, the collection of safety data regarding sensory hypersensitivity, anxiety induction, or cybersickness is still neither systematic nor sufficient [54]. In addition, equipment costs, the need for professional technical support, and the integration of intervention programs with existing rehabilitation systems are all key obstacles to their wide promotion [55]. Future intervention frameworks should include a structured "transition from virtual to real" phase and actively explore the combination with mature paradigms, such as natural developmental behavior intervention [56].

Implications for Future Research

Given the current weak and inconsistent evidence base, research in this field urgently needs to move from exploring feasibility to building high-level evidence. However, the path to high-level evidence does not begin with head-to-head trials; it begins with methodological standardization.

First and foremost, methodological standardization is an indispensable prerequisite. We strongly advocate that future research studies adopt a consensus-based core outcome set and report the specific parameters of the intervention protocol in detail to enhance comparability among studies. Without this foundational step, even large-scale comparative trials will remain nonsynthesizable and will not advance the field. Second, there is a need to design and implement head-to-head RCTs—but only after the above standardization has been achieved. Such trials should directly compare the efficacy of different VR technologies in the same population and with the same measurement tools, rather than only comparing them with passive control groups. However, until outcome measures and intervention descriptors are harmonized, the results of such trials will remain context-bound and difficult to replicate or generalize. Third, the research perspective needs to go beyond immediate effects and incorporate long-term follow-up evaluations to examine the retention and generalization of skills to real-world situations and systematically monitor and report adverse events. Finally, exploring personalized intervention matching based on individual characteristics will be an inevitable path to achieving precise rehabilitation.

In conclusion, VR offers a promising new toolkit for social skills intervention in autism. This review indicates that various forms of VR hold potential, but current research is still in its early stages, with limited and heterogeneous evidence quality. We cannot, and should not, claim any specific technology as the "best" choice based on the existing data. Future efforts should focus on strengthening the evidence base, improving technical solutions, and promoting the safe, effective, and equitable integration of VR into multimodal ASD intervention systems.

Limitations

This study has several important limitations that must be fully taken into account when interpreting its results.

First, the sparsity of the evidence network is the fundamental factor that restricts the explanatory power of this NMA. Although 11 studies were included, there were as many as 8 intervention measures being compared, resulting in many comparison nodes being supported by only a single study. This "broad but shallow" evidence structure means that, for most comparisons between technologies, the effect estimates are highly dependent on indirect evidence, thereby increasing the instability and uncertainty of the results. The ranking probability results generated under this sparse network should be regarded as extremely preliminary exploratory hints rather than conclusive efficacy rankings.

Second, this study observed significant and unexplained heterogeneity. Although we attempted to explore the sources of heterogeneity through the subgroup analysis and meta-regression, the clinical and methodological diversity among studies in terms of population characteristics, intervention details, and core outcome measurement tools constituted irreducible systematic differences. Particularly, the standardization and combination of scale scores based on different theoretical constructs and measurement units, although a methodological convention, might have obscured the specific impact of the intervention on different dimensions of social function. Therefore, the large effect size intervals and fluctuations in the combined estimates reported mainly reflect this fundamental heterogeneity, suggesting that simple quantitative synthesis may not accurately describe the complex reality. In contrast, sensitivity analyses confirmed that the extreme effect estimates were an intrinsic product of the evidence structure and not the result of individual outliers. Thus, the core value of this study lies not in the numerical results it generates, but in the fact that it clearly reveals that current evidence is insufficient for reliable quantitative comparisons. Furthermore, the classification of interventions and comparators, while necessary for quantitative synthesis, itself introduces a source of heterogeneity. This clinical and methodological diversity directly challenges the similarity assumption required for a robust NMA and is a primary reason for the high statistical heterogeneity observed and the wide confidence intervals in our effect estimates.

Third, there may be language and search biases. To ensure the feasibility of the search, the language of the literature in this review was limited to Chinese and English, which might have resulted in missing relevant studies published in other languages, thereby affecting the comprehensiveness of the evidence base.

Fourth, the depth and breadth of outcome measures are insufficient. All included studies focused on the immediate postintervention effects and generally lacked medium- and

XSL•FO
RenderX

long-term follow-up data, thus making it impossible to assess the sustainability of VR intervention effects and their generalization to real-life scenarios. Additionally, for the ASD population, which is sensitive to sensory stimuli, only a few studies systematically reported adverse reactions or reasons for dropout, leaving a gap in the comprehensive assessment of the safety profile of VR technology, especially immersive devices.

Finally, the risk of bias in the included studies should be treated with caution. Nearly half of the studies had "some concerns" or "high risk" in the randomization process or blinding implementation, which might have affected the internal validity of the effect estimates to some extent. Although the sensitivity analysis showed that the direction of the main conclusion remained unchanged after excluding the high-risk studies, this risk indicates that more methodologically rigorous studies are needed in the future to strengthen the evidence base.

Conclusion

This is the first NMA to quantitatively compare diverse VR technologies for improving social and communication skills in children with ASD. The most salient finding is not about the superiority of any specific technology but rather about the current state of the evidence base: it is too limited, heterogeneous, and methodologically inconsistent to support reliable conclusions regarding comparative effectiveness.

The core value of this study lies in systematically reviewing the current evidence, highlighting the key gaps that need to be addressed and demonstrating that the evidence is not yet ready for comparative synthesis. Future research must make breakthroughs in the following areas: first, more high-quality, large-sample RCTs should be conducted, especially those directly comparing different VR technologies, to provide more reliable data on therapeutic efficacy. Second, efforts should be made to standardize outcome measurement tools and use consensus-based core sets of indicators to enhance comparability among studies and the accumulation of evidence. Third, long-term efficacy and safety must be emphasized, including the assessment of skill maintenance, generalization, and potential risks associated with technology use. Fourth, individualized intervention plans based on personal characteristics should be explored to determine which technologies are most suitable for different types of children with autism.

In conclusion, VR shows promising potential as an intervention tool, but its evidence base is still in its infancy. The current research findings should be regarded as generating hypotheses about which technologies merit further investigation, not as validating conclusions about their comparative effectiveness. We call on the academic community to work together to advance methodological harmonization as the essential foundation for all subsequent comparative research studies.

Abstract

Background: In response to the COVID-19 pandemic, governments around the world enforced stay-at-home orders and social distancing guidelines that amplified the use of screen time among pediatric populations. Excessive screen time may negatively impact mental health by increasing depression and anxiety.

Objective: The first aim was to conduct a systematic review of articles examining screen time and mental health outcomes among children and adolescents during the COVID-19 pandemic from 2020 to 2023. The second aim was to determine the combined effect sizes for the associations of screen time and depression and/or anxiety among children and adolescents during the COVID-19 pandemic from 2020 to 2023 and whether gender or age influenced outcomes.

Methods: Bibliographic databases were searched including MEDLINE (Ovid), Embase (Elsevier), Cochrane Library (Wiley), CINAHL Complete (EBSCO), and PsycINFO (EBSCO). There were a total of 6462 nonduplicate studies that were screened. Study inclusion criteria included children ages 0 to <18 years, the effects of screen time on children during the COVID-19 pandemic, screen time and depression and/or anxiety, articles written in English, and articles, including quantitative and qualitative studies, published between 2020 and 2023. A total of 452 articles underwent full-text review with 23 articles meeting criteria for final article extraction.

Results: A total of 23 studies totaling 29,581 children and adolescents were included in the study. Results showed that most studies reported a positive association between screen time and depression and/or anxiety (r=0.175, 95% CI 0.124-0.226, P<.001 and r=0.157, 95% CI 0.0994-0.214, P<.001, respectively) during COVID-19. Meta-regression revealed that screen time measured in problematic use of electronic devices had a 0.15 higher correlation with anxiety compared to screen time measured in duration of electronic device use.

Conclusions: During the COVID-19 pandemic, children and adolescents with higher levels of screen time had increased depression and/or anxiety. Findings suggest the need for ongoing parent, professional, and self-monitoring of youth screen behaviors and habits as well as activities that promote social connectedness during global or national health emergencies.

KEYWORDS

screen time; anxiety; depression; COVID-19 pandemic; children; adolescents; mental health

Introduction

The global COVID-19 pandemic impacted children's screen time. As numerous restrictions were put on children and adolescents during COVID-19, regular screen usage increased due to the closure of regular outdoor activities and increase in online learning. A meta-analysis of over 29,000 children showed a 52% increase in screen time, particularly for those aged 12 - 18 years [1]. Excessive screen time increased, with adolescents reported to have almost 6 hours per day of screen use, mainly spent on watching shows, movies, and playing games [2]. One-third of adolescents aged 13 - 17 years reported using social media "almost constantly" [3]. Children at 9.5 years of age who were surveyed during the COVID-19 pandemic

XSL•FO
RenderX

reported an average increase in recreational screen time of 11 hours per week compared to the 1 hour per week increase reported in prepandemic surveys conducted at ages 5 and 8 years [4].

The COVID-19 pandemic also exacerbated the preexisting mental health challenges of children and adolescents [5]. A meta-analysis covering over 80,000 youths globally found that the prevalence of anxiety and depression doubled during the COVID-19 pandemic to 20% - 25% [6]. In the United States, emergency visits for children due to mental health problems rose drastically by 31% - 50% since the beginning of the pandemic [7]. Globally, depression and posttraumatic stress disorder were significantly more prevalent among children aged 7 to 15 years [8] due to the separation from classmates and friends. Overall, distancing measures during the pandemic were harmful to adolescent mental health [9].

The opportunity for excessive screen use during the COVID-19 pandemic also impacted mental health outcomes among children and adolescents. Social media and media addiction were associated with ill-being among adolescents [9]. The US Surgeon General released a report [10] indicating potential risks of social media use on the mental health of children and adolescents and called for more evidence. During the pandemic, a greater duration of screen time (such as television viewing [10] or digital media time [10], including social media use [11,12]) was associated with higher levels of depression and anxiety [12]. The associations between screen time and poor mental health outcomes have been found in individual studies; however, to our knowledge, there have not been meta-analyses of screen time using standardized or validated measures of depression and anxiety during the pandemic.

Thus, this review aims to fill this gap by examining the mental health effects of screen time in children and adolescents throughout the COVID-19 pandemic. First, the purpose was to conduct a systematic review of articles examining screen time and depression and anxiety among children and adolescents during the COVID-19 pandemic from 2020 to 2023. Second, the purpose was to determine the combined effect size for the association of screen time and depression and anxiety among children and adolescents during the COVID-19 pandemic from 2020 to 2023. We additionally explored the influence of gender and age on the relationship between screen time and mental health outcomes.

Methods

Eligibility Criteria

Studies identified through database searches were screened for the following inclusion criteria: (1) children ages 0 to <18 years, (2) examination of the effects of screen time on children during the COVID-19 pandemic (eg, video games, smartphone use, or computer use), (3) examination of screen time and anxiety and/or depression, (4) articles were written in English, and (5) studies, including quantitative and qualitative studies, published between 2020 and 2023. Studies were excluded if they did not describe the effects of screen time on children during the COVID-19 pandemic (eg, provider-led and provider-care interventions; telehealth) or did not meet the inclusion criteria listed above.

Information Sources and Search Strategy

We initially searched the following bibliographic databases: MEDLINE (Ovid), Embase (Elsevier), Cochrane Library (Wiley), CINAHL Complete (EBSCO), and PsycINFO (EBSCO). A MEDLINE search strategy was created using a combination of Medical Subject Headings (MeSH) and keywords for the concepts of COVID-19, screen time, and pediatrics. All team members reviewed the strategy and results; with team approval, the search was customized using controlled vocabulary (when available) and keywords in Embase, Cochrane Library, and PsycINFO (Multimedia Appendix 1). As of November 2021, all resulting citations were exported into an EndNote 20 (Clarivate Analytics) library with duplicates removed [13]. The resulting collection of citations was then imported into Covidence for screening. In August 2022, the search was run again in all bibliographic databases and any unique citations were imported into Covidence. Finally, in February 2023, the search was rerun given the refinement of the research question to include validated measures of depression and anxiety and to capture new studies that had been recently published. This was done again in MEDLINE and PsycINFO and also included CINAHL. All articles were imported and screened in Covidence.

Data Collection Process

Two reviewers independently extracted data from each article and the extracted data were sent to the research team for consensus. The following data were extracted from each study: the first author, the date and place of publication, the number of participants enrolled, participant demographics, measures/assessments used, study start and end date, inclusion criteria, findings summary, and effect sizes. The extracted data were collected in Covidence. Any disagreements were resolved in discussions with the research team.

Screen time during the COVID-19 pandemic, including problematic use that was excessive or disordered (eg, video games, smartphone or computer use, social media use), was defined through self-reports of screen time duration. Anxiety was defined using self-report standardized questionnaires as well as standardized parent report measures on anxiety symptoms. Depression was defined using self-report standardized questionnaires as well as standardized parent report measures on depressive symptoms.

Study Risk of Bias Assessment

The STROBE (Strengthening the Reporting of Observational studies in Epidemiology) checklist was used to assess the quality of included studies on a scale from 0 to 21 (Table 1) [14]. Two reviewers assessed each study independently and then met to achieve consensus.

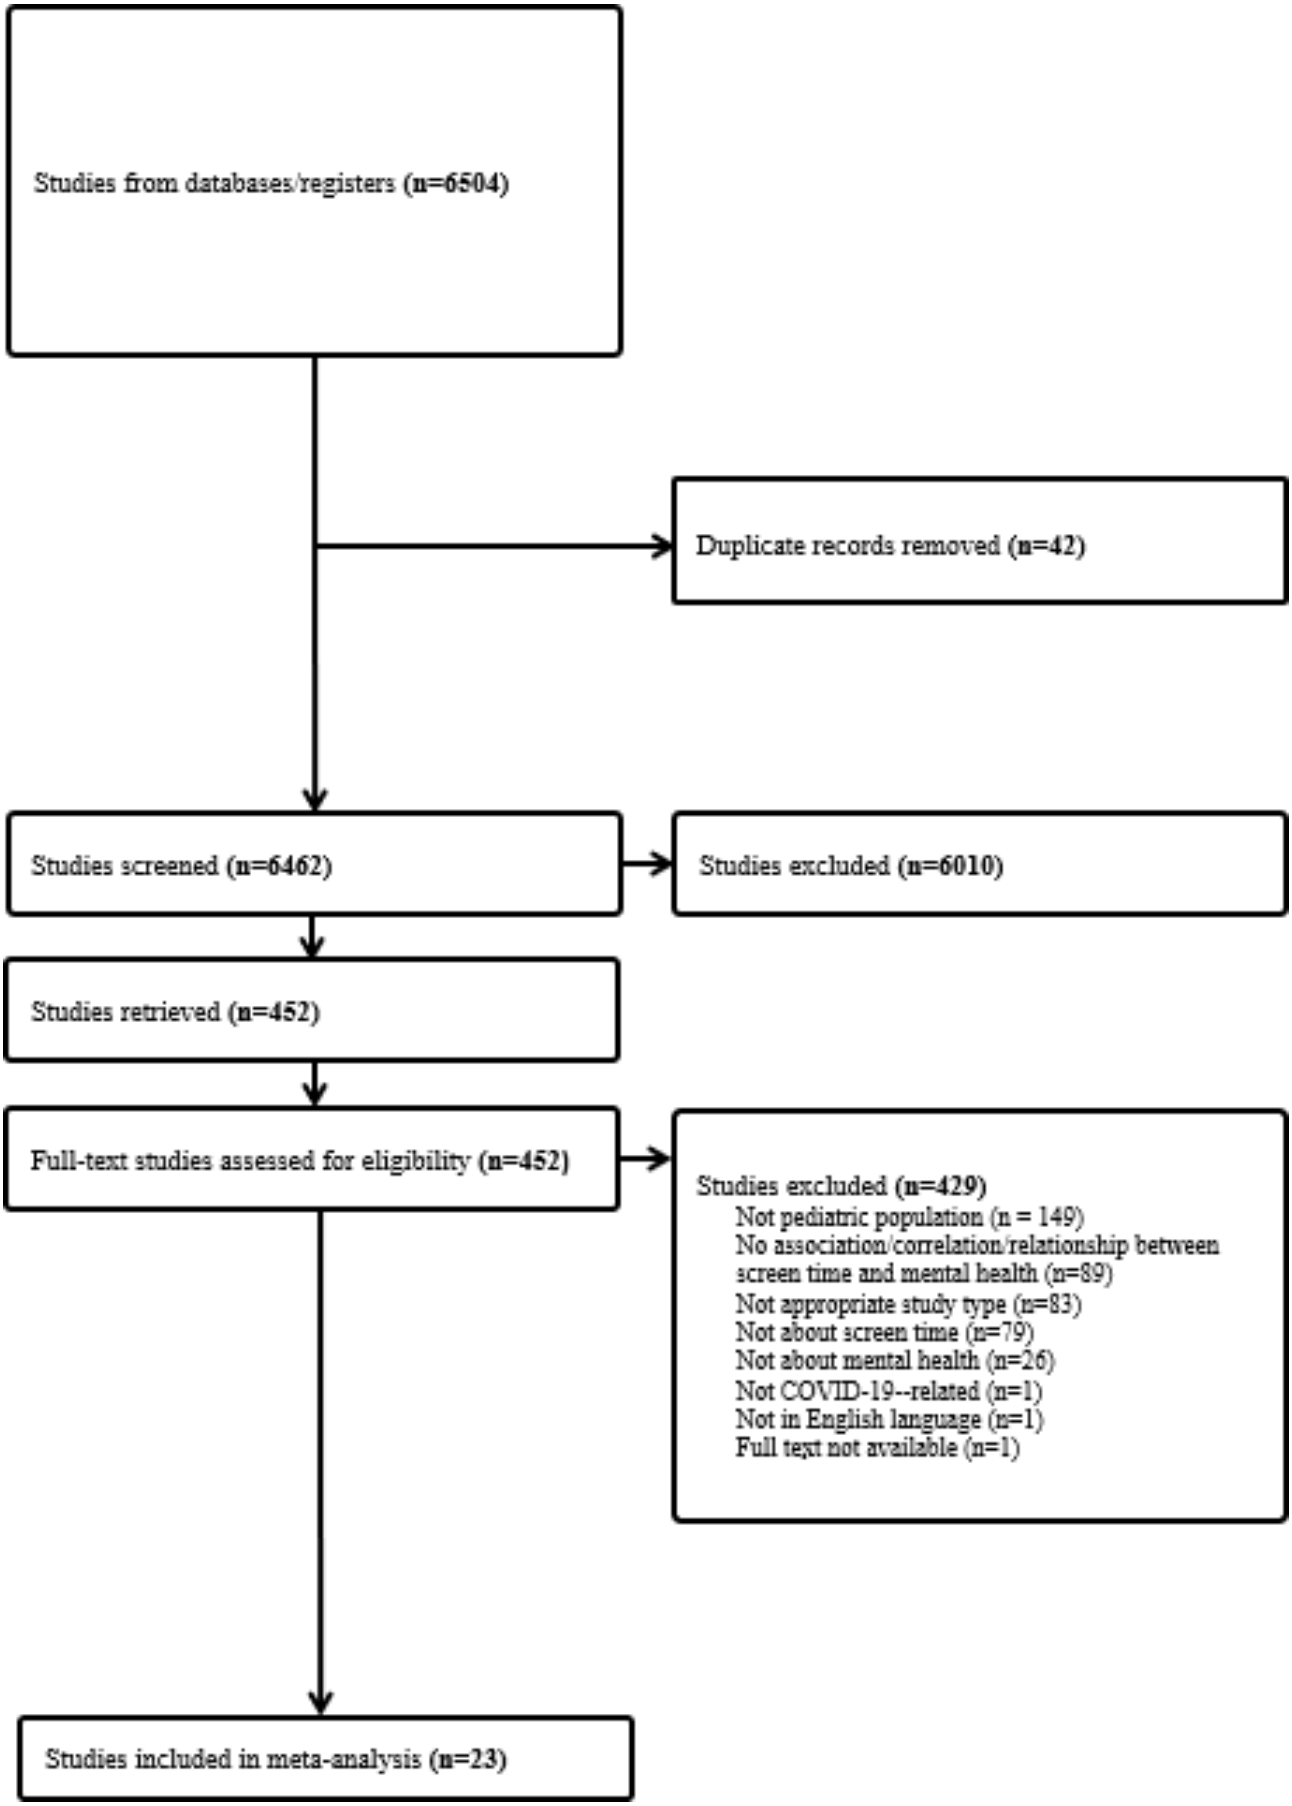
Effect Measures, Synthesis Methods, and Analyses

Fisher *r*-to-*z* transformation was used as the effect measure to quantify the relationship between screen time, anxiety, and depression, and results were converted back to Pearson correlations for interpretation. Studies were excluded if they were missing sufficient summary statistics and/or were unconvertible into appropriate effect sizes. Studies reported in other effect measures were converted to correlations using the conversion formulas proposed by Borenstein et al [14]. If a study assessed the same outcome with more than one measure, the average effect size was used in the analysis [36].

A random-effects model was used for all meta-analysis to account for heterogeneity across studies. Pooled correlations of r=0.10, r=0.30, and r=0.50 were considered as small, medium, and large effect sizes, respectively [37]. Heterogeneity (ie, $\tau 2$) was assessed using the restricted maximum-likelihood estimator. In addition to the estimation of $\tau 2$, the Q test for heterogeneity and the I^2 statistics are also reported [38]. Forest plots were generated for each outcome to visualize individual study effects and pooled estimates. Funnel plots were used to detect potential publication bias. Meta-regression analysis was performed to assess the impact of age, gender, and the definition of screen time (duration of use vs problematic use) on the effect sizes [39]. To evaluate the robustness of the results, sensitivity analysis was conducted by excluding studies identified as potential outliers or exerting excessive influence on the pooled effect using studentized residuals and the Cook distance [40]. All statistical analyses were performed using RStudio (version 4.4.1; Posit PBC) and the *metafor* package [41].



Results

Search Results and Included Studies

In the initial database search, 6504 records were obtained. After duplicate removal, the titles and abstracts of 6462 records were screened independently by 7 coders based on the predefined eligibility criteria. After the title and abstract screening, 452 articles were retained. Following full-text screening, 429 articles were excluded from the systematic review, and 23 articles totaling 29,581 children and adolescents were retained in the systematic review and meta-analysis. See Figure 1 for the PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) flow diagram of observational studies.

Study Characteristics

Across the 23 studies (Table 2), children and adolescents were 8 to <18 years of age, with a mean age of 13.54 (SD 0.43) years; in addition, 49% (n=14,390) were male and 51% (n=15,191) were female. Of the 23 studies, 39% (n=9) were from North America, 44% (n=10) were from Asia, and 17% (n=4) were from Europe. Studies were published globally in the following countries: United States (n=6), China (n=6), Canada (n=3), Hong Kong (n=1), Hungary (n=1), Italy (n=2), India (n=1), Iran (n=1), Poland (n=1), and South Korea (n=1). Of the 23 studies, 96% (n=22) examined depression, 83% (n=19) examined anxiety, and 78% (n=18) examined both depression and anxiety.

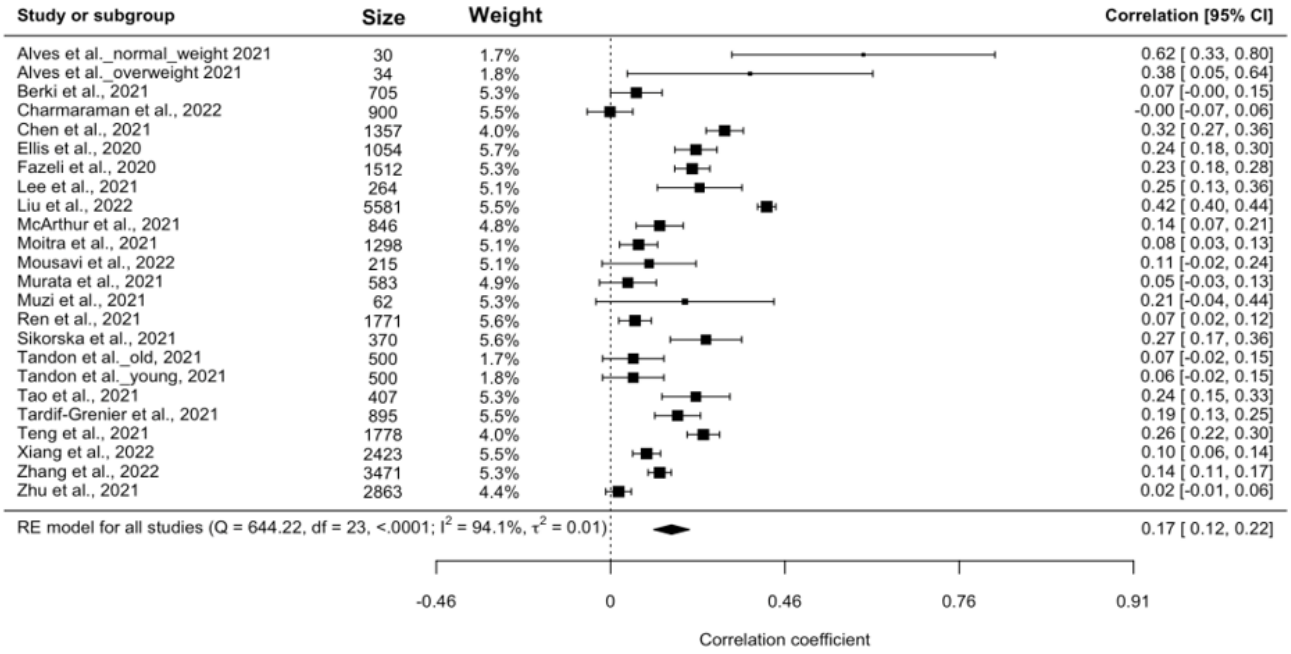
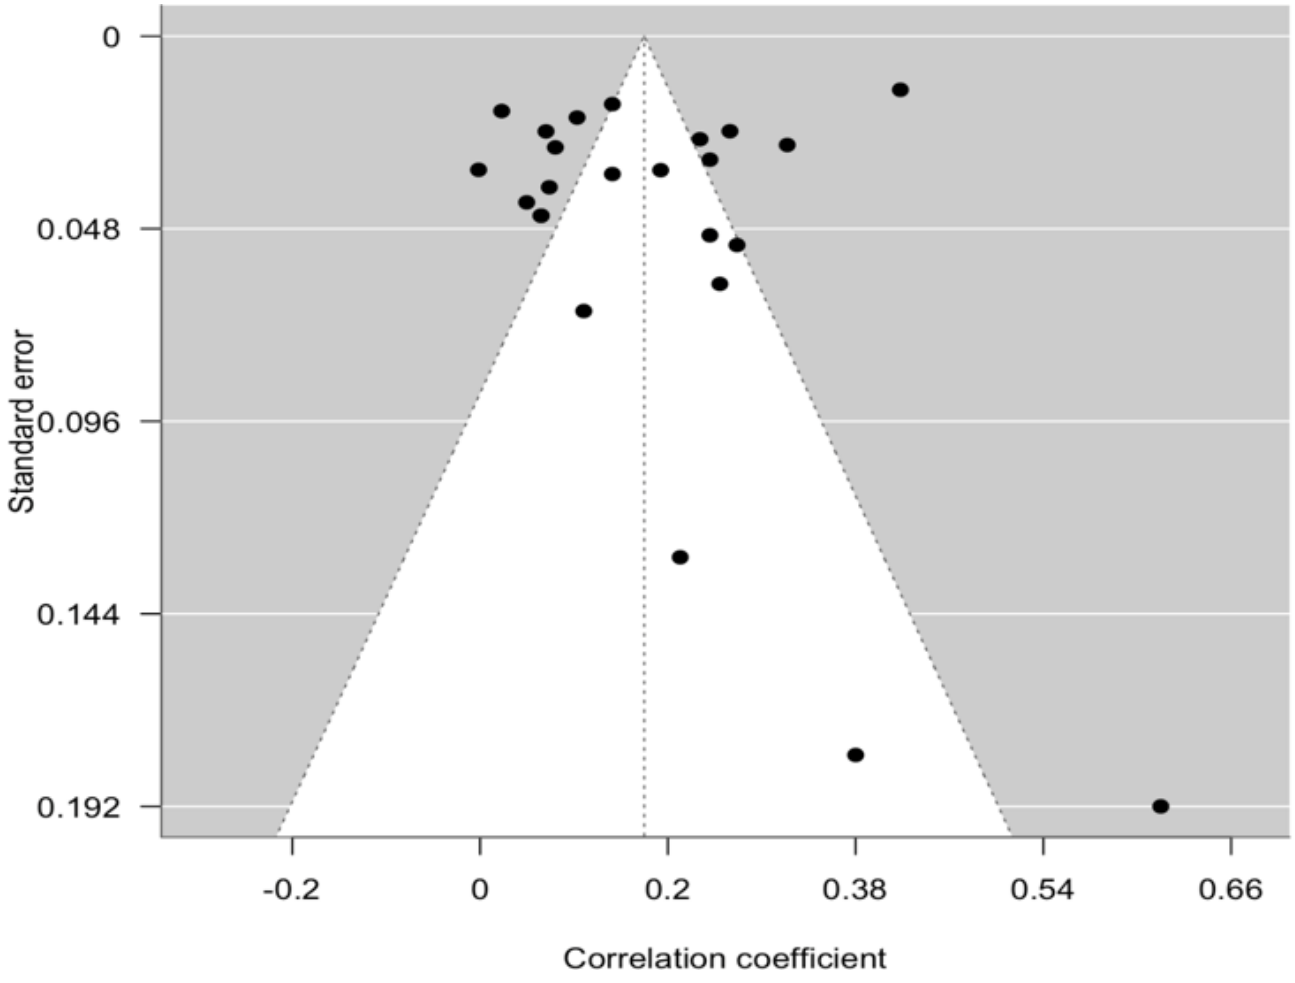
Risk of Bias in Studies



The STROBE checklist [14] was used to assess the quality of studies and any potential bias as seen in Table 1. Two independent reviewers assessed each study, resulting in a possible score from 0 to 20. Each section of the STROBE checklist had a potential score of 0 to 2, with 0 meaning criteria were not met, 1 meaning criteria were partially met, and 2 meaning criteria were fully met. Two reviewers ranked the scores, and any disagreements were discussed with a third reviewer to achieve consensus. All studies used validated questionnaires for depression and anxiety. McArthur et al [23] used a large longitudinal cohort, which allowed for examination of differences over time. The majority of studies were cross-sectional and were conducted during the global pandemic, which did not allow for examination of causal relationships. The following studies were found to have a lower quality assessment. De Pasquale et al [42] did not provide any information on the statistical tests that were conducted in the methods. Fazeli et al [20] had limited information on the statistical methods. Moitra and Madan [24] conducted a mediation analysis on a cross-sectional study but did not indicate the temporal order in their survey methods. Zhu et al [35] imputed more than 25% of missing data. Sikorska et al [29] did not adequately address potential limitations.

Screen Time and Depression

Twenty-two of the 23 included studies (all except [42]) reported comparable effect sizes for screen time and depression. Two studies [15,30] presented results only for stratified subgroups rather than an overall sample. Therefore, we treated the stratified groups as separate studies in the analysis and increased the sample size to 24 for the analysis. The observed correlation coefficients ranged from −0.00160 to 0.620. The random-effects model revealed a significant, positive, small estimated pooled correlation (r=0.175, 95% CI 0.124-0.226; P<.001; I^2=94%). According to the Q test, the true estimates appear to be heterogeneous (Q_{23}=644.22, P<.001, τ2=0.0138, I^2=95%). A forest plot showing the observed and the estimated correlation is shown in Figure 2 [11,15-31,33-35]. Meta-regression showed no significant associations of depression with age and gender.

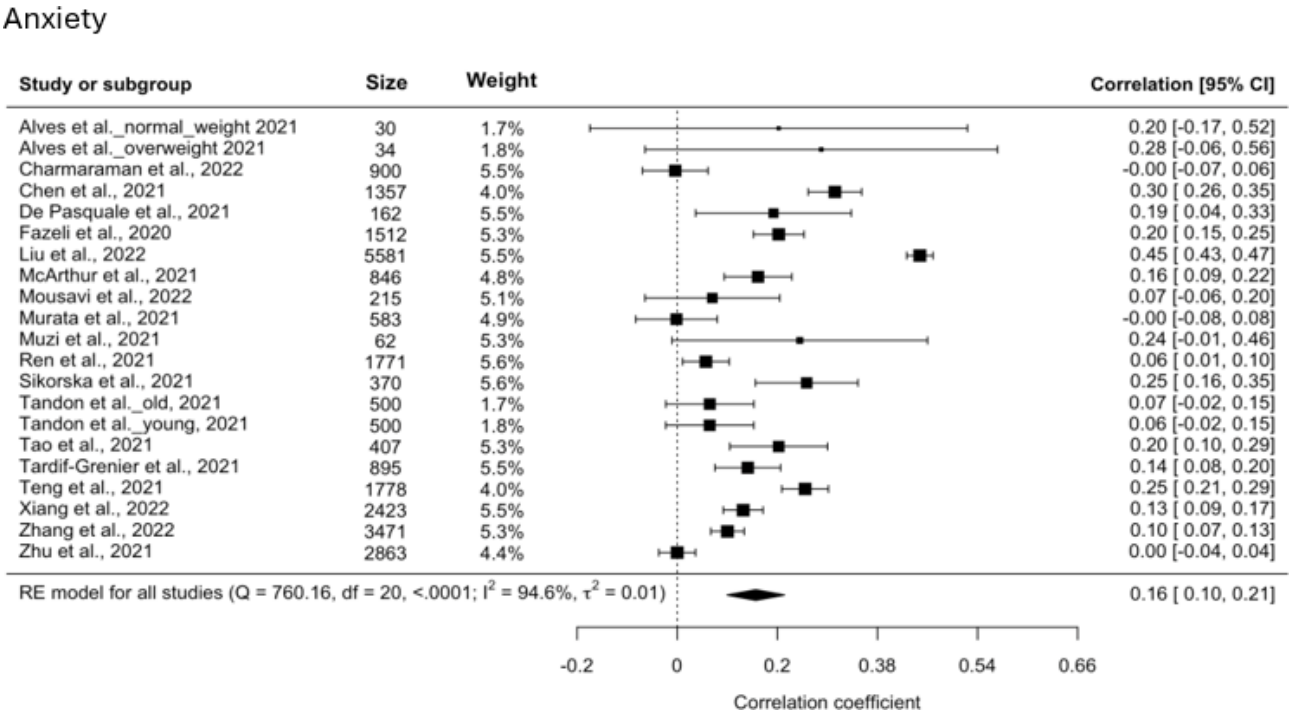


XSL•FO
RenderX

Figure 2. Forest plot for depression.

A funnel plot of the estimates is shown in Figure 3. The plot is reasonably symmetrical around the pooled estimate, indicating no strong evidence of publication bias or small-study effects. Both the Cook distance and studentized residuals showed that one study [22] could be overly influential. Sensitivity analysis was conducted by removing the study. The result from the sensitivity analysis remained stable after removing the potential outlier (r=0.158, 95% CI 0.114-0.202; P<.001), supporting the result from the main analysis. Although I^2 decreased from 95% to 90%, heterogeneity remained high across studies.

Figure 3. Funnel plot for depression.

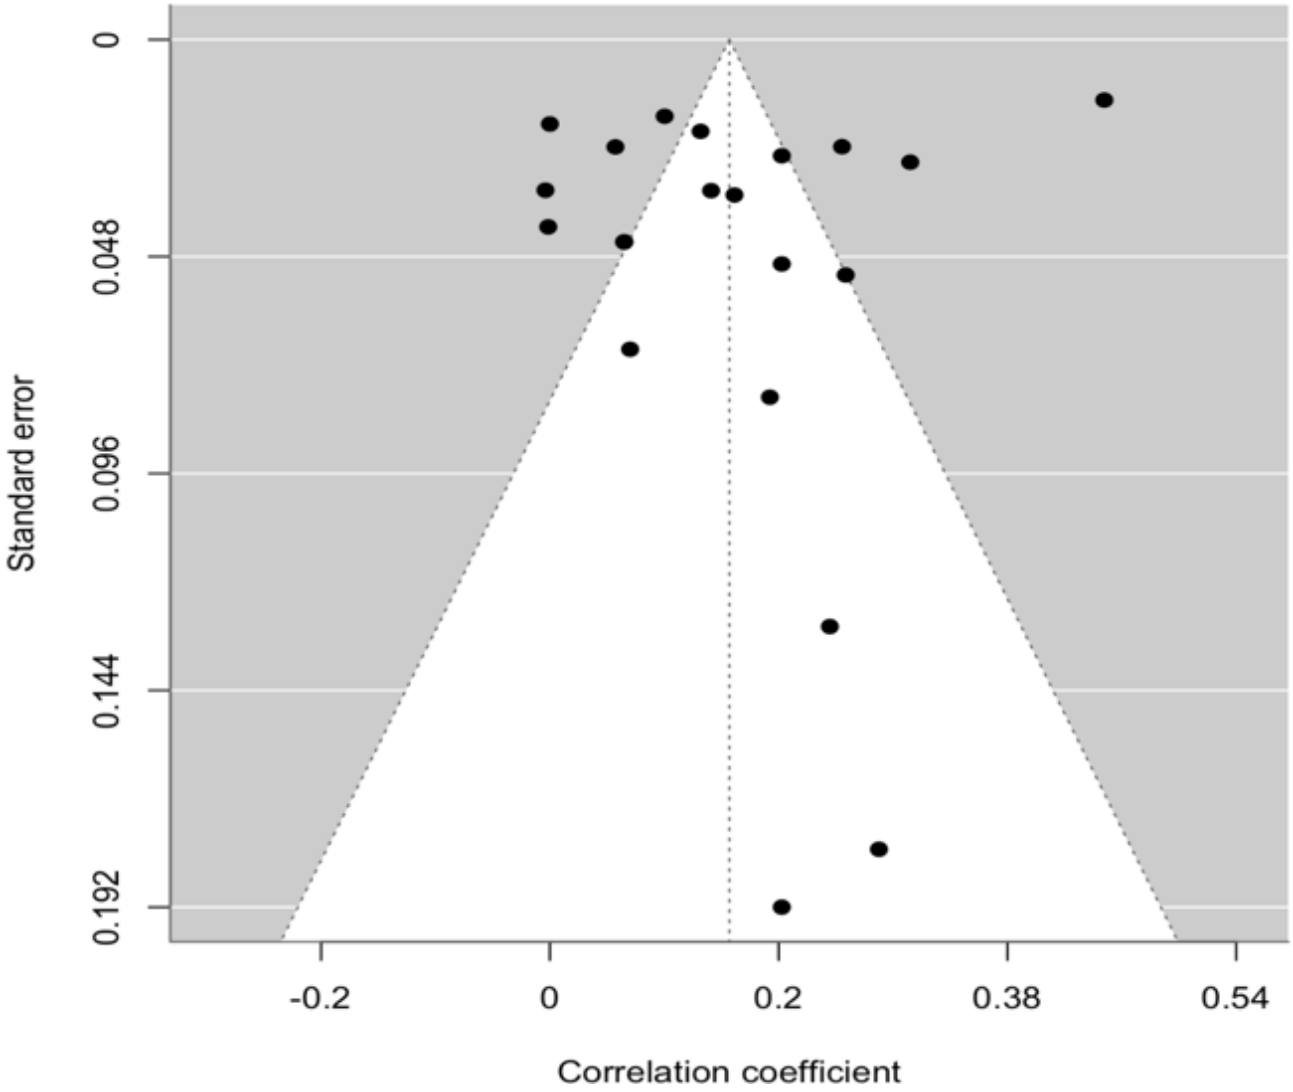


XSL•FO
RenderX

Screen Time and Anxiety

A total of 19 studies reported correlation coefficients for screen time and anxiety, ranging from −0.00390 to 0.450. Since the results from Alves et al [15] and Tandon et al [30] were reported as two stratified subgroups, it increased the total sample size to 21 for the analysis. A random-effects model for screen time and anxiety again indicated a significant yet small estimated pooled correlation (r=0.157, 95% CI 0.0994-0.214; P<.001), with a Q test (Q_{20}=760.16, P<.001,τ2=0.0150, I^2=95%) demonstrating high heterogeneity. A forest plot showing the observed and estimated correlations is shown in Figure 4 [11,15,17,18,20,22,23,25-30,33-35,42]. Meta-regression revealed that compared to studies where screen time was measured as duration of use, those defining it as problematic use have an average 0.1585 higher Fisher z score for the correlation between screen time and anxiety. In terms of correlation, this translates to roughly a 0.15 increase, indicating a stronger correlation with anxiety in studies with problematic use.

Figure 4. Forest plot for anxiety.



Certainty of Evidence

The funnel plot in Figure 5 was fairly symmetrical around the pooled effect size visually, with no indication of publication bias or small-study effects. The same study [22] was considered to be an outlier based on the Cook distance and studentized residual. The result from the sensitivity analysis yielded a slightly lower but still significant correlation (r=0.135, 95% CI 0.0890-0.181; P<.001), supporting the result from the main analysis. Although I^2 decreased from 95% to 89%, heterogeneity remained high overall, suggesting the true effect varies across different studies.

RenderX

Figure 5. Funnel plot for anxiety.

Discussion

Principal Findings

This meta-analysis of a total of 23 global studies examined screen time and mental health outcomes among 29,581 children and adolescents during the COVID-19 pandemic. Screen time had a significant, positive, small estimated pooled correlation with increased depression (22 studies) and increased anxiety (19 studies). Problematic screen use that was excessive or disordered had a stronger correlation with anxiety than average screen use. Age and gender did not influence mental health outcomes; most youth were adolescents and gender was equally distributed. Sensitivity analyses for studies with outliers for depression and anxiety supported the results from the main analysis.

Although various studies examined different types of screen time during the pandemic, results remained the same. Studies reported greater time spent on social media was associated with higher depressive [11,19] and anxiety symptoms [11]. Zhu et al [35] reported pathological gaming behavior (as compared to excessive, leisure, and none) was associated with increased depression and anxiety. Berki et al [16] reported that more hours of daily screen time (time spent using electronic devices such as a computer, tablet, or smartphone) were associated with higher depressive symptoms. Studies also found that a greater number of hours spent on video games and social media predicted higher depressive [18,26,43] and anxiety [18] symptoms and negative perceived well-being [44].

Strengths

There were various strengths in this meta-analysis. A rigorous process was implemented, with multiple reviewers using a systematic approach to achieve consensus when screening studies for eligibility and extracting data from studies that met eligibility criteria. Additionally, depression and anxiety were measured using validated questionnaires, and the meta-analysis methodology provided precision in the estimate of the effect size, which increased the validity and generalizability of the findings. Extracted studies included pooled data from 10 countries in North America, Europe, and Asia, further increasing the generalizability of the findings. Sensitivity analyses demonstrated the robustness of the study results. Finally, the COVID-19 pandemic was a global emergency that served as a natural experiment and magnified the conditions to allow youth to participate in excessive screen time, providing a rare

XSL•FO
RenderX

opportunity with high statistical power to examine the impact on mental health outcomes.

Limitations

There were limitations in this study. Most studies examined the negative impact of screen time, which may have introduced some bias. Given the unprecedented nature of the global pandemic, most studies were cross-sectional, allowing for the examination of the relationship between screen time and increased depression or anxiety at one point in time. The results are not generalizable to all age groups as the cohort mostly consisted of adolescents, with a mean age of 13.54 years. More information is needed about how the COVID-19 pandemic impacted school-age (6 - 12 year olds) and young children (0 - 5 year olds). Screen time was also measured through youth self-reports or parent reports, which may not accurately reflect the amount of time spent on screens due to recall bias. It is possible that other factors aside from screen time, such as the adjustment to the online schooling format and/or cybervictimization, may have impacted anxiety and depression. Since this study included data from multiple countries, there may have been different methods for collecting and tracking data, and it is possible that some mental health data could have been underreported.

Clinical Implications

During the pandemic, children and adolescents with increased screen time were negatively impacted in terms of depression and anxiety due to higher levels of screen time. These findings suggest the need for ongoing assessment of children and adolescents' quality and quantity of screen behaviors to identify risk factors to prevent or treat mental health outcomes, especially in the event of another global or national emergency. More research is needed to develop a validated tool to assess screen time [45,46]. Given the significance of screen time in the lives of youth, it is important to consider how to address unhealthy media habits that may increase during a pandemic. The American Academy of Pediatrics recommends the 5 Cs of Media Use to promote healthy media habits [47]. This includes Child, Content, Calm, Crowding Out, and Communication. Practitioners should work with families to develop family media plans that address rules around screen time, balancing family and media time, conversations around responsible social media use, teaching emotion regulation strategies, parental modeling of screen use, and monitoring content for quality, developmental appropriateness, and privacy. Additionally, pediatricians can provide anticipatory guidance to help children and families prepare for emergencies, such as a global pandemic [48]. Children and adolescents should learn from an early age about the benefits and risks of screen use, with an emphasis on developing healthy screen habits that maximize positive social interactions, learning, and recreation; increasing awareness of safety factors such as the protection of privacy; and creating self-awareness that will guard against the negative impacts on mental health related to screen overuse. Finally, promoting positive childhood experiences during a global emergency may help to buffer negative impacts of excessive screen time on mental health outcomes by nurturing healthy social-emotional development.

Conclusion

This meta-analysis includes the evidence from 23 studies on screen time and mental health. During the COVID-19 pandemic, children and adolescents with higher levels of screen time had increased depression and/or anxiety. These data suggest the need for ongoing parent, professional, and self-monitoring of youth screen behaviors and habits as well as activities that promote social connectedness during global or national health emergencies.

Abstract

Background: Virtual, augmented, mixed, and other immersive technologies, collectively referred to as extended reality (XR), are increasingly used to enhance experiential learning in health education. By creating interactive 3-dimensional or 360° environments, these technologies allow expectant parents to engage in realistic prenatal and childbirth scenarios, promoting emotional preparedness, knowledge acquisition, and confidence. Although XR has been widely studied in clinical training, its application in prenatal and childbirth education for parents remains less systematically explored.

Objective: This scoping review aims to map and synthesize the current evidence on the use of virtual, augmented, mixed, and immersive technologies in prenatal and childbirth education, highlighting their educational benefits, methodological approaches, and implementation challenges.

Methods: A comprehensive search was conducted across Scopus, Web of Science, PubMed, CINAHL, IEEE Xplore, APA PsycINFO, and APA PsycArticles from inception to October 16, 2025. Search terms included “virtual reality,” “augmented reality,” “mixed reality,” “extended reality,” and “immersive technology,” combined with prenatal and childbirth education descriptors. Studies were included if they applied immersive or XR technologies to deliver prenatal or childbirth education for expectant parents. Screening and data extraction were performed independently by 2 reviewers following PRISMA-ScR (Preferred Reporting Items for Systematic Reviews and Meta-Analyses extension for Scoping Reviews) guidelines. The review was registered on Open Science Framework (OSF).

Results: From 1861 records, 11 studies from 8 countries were included, spanning randomized controlled, quasi-experimental, feasibility, and qualitative designs. Interventions comprised head-mounted display–based virtual reality, 360° video, and mixed reality simulations. Outcomes covered psychological, physiological, educational, and experiential domains. Most studies reported feasibility and high engagement, with encouraging signals for reduced anxiety and improved birth preparedness and, in some cases, reductions in pain and intrapartum indicators. No serious adverse events were reported; nausea and discomfort were infrequent and transient. Thematic analysis identified 5 recurring themes: enhanced birth preparedness, realism and presence as a key mechanism, usability barriers and the need for guided facilitation, motivational and educational potential, and limited partner inclusion. Methodological quality was heterogeneous, with small samples, nonstandardized measures, and short follow-up.

Conclusions: Evidence for XR in prenatal education is promising yet preliminary. Rigorous multicenter studies with standardized outcomes, longer follow-up, and greater partner involvement, alongside attention to equitable access and digital literacy, are needed to support integration into maternity care pathways.

extended reality; immersive technology; augmented reality; mixed reality; 360° video; virtual reality; childbirth education; parental education; prenatal education; breastfeeding

Introduction

Background and Importance of Prenatal Education

Prenatal education plays a pivotal role in preparing expectant parents for childbirth and early parenthood. Traditionally, such education has been delivered through in-person classes, with the goal of fostering confidence and informed decision-making during pregnancy [1-3]. Improving parental emotional readiness has also been associated with better neonatal outcomes, including reduced complications at birth, underscoring the indirect benefits of prenatal education on child health [4,5].

XSL•FO
RenderX

Beyond knowledge acquisition, prenatal programs aim to enhance emotional preparedness, self-efficacy, and engagement, factors that can significantly influence maternal and neonatal well-being [6].

Limitations of Traditional Approaches

Despite its recognized importance, participation in conventional prenatal education programs may be complicated and at times impeded due to time constraints, work demands, and logistical or transportation barriers [7]. Traditional didactic formats often provide limited experiential engagement and may fail to adequately address psychological aspects such as fear of childbirth (FOC) and anxiety; a randomized controlled trial (RCT) evaluates an 8-week integrated childbirth education program that combines labor simulations with mindfulness practices to better target these needs. Compared with standard prenatal care, the program significantly reduced FOC, anxiety, and depressive symptoms and increased dispositional mindfulness through early postpartum, suggesting that integrative approaches (such as mindfulness) can improve the impact of the traditional prenatal education programs, for example, improving perinatal mental health in women with high FOC [8]. Pregnancy is widely recognized as a sensitive period in which psychological distress, including fear, anxiety, and depression, can negatively affect both maternal and neonatal outcomes [5,9]. Common concerns include miscarriage, fetal abnormalities, labor pain, and the perceived ability to be a "good mother." Studies have shown that FOC, particularly in late pregnancy, may contribute to avoidance behaviors such as elective cesarean section [9,10]. Nonpharmacological interventions, including hypnosis, physical activity, and cognitive-behavioral strategies, have been trialed to mitigate childbirth-related anxiety with mixed but promising results [11-13]. Overall, prenatal education remains a widely accessible and effective strategy to empower parents and promote positive maternal and infant outcomes [14-16].

The Use of Virtual, Augmented, Mixed, and Immersive Technologies in Prenatal Education

With the growing digitization of health care and the evolving needs of diverse parent populations, innovative approaches to prenatal education are increasingly being explored.

Extended reality (XR) is an umbrella term encompassing virtual reality (VR), augmented reality (AR), and mixed reality (MR) technologies, which collectively enable users to interact with digital environments and objects beyond traditional screen-based media. XR systems differ in the degree of immersion and integration between virtual and physical elements, including (1) VR, which provides full immersion in a computer-generated environment, typically via a head-mounted display (HMD) that occludes the physical world; (2) AR, which overlays digital information or objects onto the real environment, maintaining users' awareness of their surroundings; and (3) MR, which allows real and virtual elements to coexist and interact in real time, creating a seamless hybrid environment. These immersive systems leverage high-resolution audiovisual displays, motion tracking, and multisensory feedback (eg, haptic or spatial audio) to generate a sense of presence and involvement, key dimensions of the immersive experience [17,18]. In this review, XR and immersive technologies are defined as digital simulation environments, ranging from fully immersive VR headsets to semi-immersive 360° video and mobile-based apps, designed to support experiential learning and emotional engagement during prenatal and childbirth education [19,20]. By providing immersive, interactive simulations, XR could enable users to experience realistic childbirth environments in a safe and controlled setting, potentially enhancing understanding, emotional preparedness, and engagement, especially among first-time parents or those with limited access to conventional resources [21]. While the use of XR in clinical training for health care professionals is well established [22], its application for patient-facing prenatal education remains relatively understudied. Early studies suggest that immersive interventions, administered in different phases of the childbirth process, may reduce childbirth-related anxiety, improve systolic blood pressure, decrease maternal heart rate, and even increase fetal movement acceleration [23,24]. Furthermore, XR-based interventions can offer increased flexibility and accessibility, potentially reducing geographic and socioeconomic barriers to participation [25].

Recent randomized trials and systematic reviews have begun to consolidate the evidence base for immersive technologies in perinatal care. VR used during labor or cesarean birth has been associated with reductions in pain and anxiety and improvements in birth satisfaction, without major safety concerns for mothers or newborns [21,26,27]. In parallel, VR-based prenatal education and broader programs for pregnant women have reported gains in childbirth knowledge, self-efficacy, and pregnancy-related anxiety, suggesting that immersive tools can strengthen both cognitive and emotional preparation for birth [24]. These developments highlight the need for a focused synthesis of XR specifically in parent-facing prenatal and childbirth education, beyond the more established literature on clinician training.

Public Health and Psychosocial Context

Beyond technological innovation, prenatal education is a key component of global maternal health policy. The World Health Organization (WHO) has emphasized the importance of high-quality, integrated maternity services that ensure a positive pregnancy and childbirth experience [28]. Within this framework, addressing maternal emotional well-being, particularly anxiety and FOC, is considered a central priority. Immersive technologies can contribute to these goals by providing emotionally engaging and accessible educational experiences, supporting both knowledge acquisition and psychological resilience during pregnancy [29,30].

Pedagogical Frameworks Supporting the Use of Immersive Technologies

The educational value of immersive technologies is supported by several pedagogical models. The Interaction Model of Client Health Behavior (IMCHB) emphasizes the role of emotionally resonant and individualized learning experiences in shaping behavior change [31]. Likewise, constructivist learning theory posits that experiential and interactive simulations facilitate understanding through active, context-based engagement, allowing learners to integrate new information with prior experiences [32]. The Cognitive Load Theory offers a

XSL•FO
RenderX

complementary framework, suggesting that well-designed XR content can enhance learning by minimizing extraneous cognitive demands and improving retention through multimodal cues such as narration, interactivity, and visual emphasis [33]. Together, these models support the potential of XR-based prenatal education to foster active, meaningful, and self-directed learning.

Challenges and Research Gap

Despite its promise, XR-based prenatal education faces several challenges, including usability issues (eg, cybersickness, device discomfort, and limited digital literacy), ethical concerns about replacing human interaction, and potential inequalities in access. Existing research is also limited by methodological heterogeneity, small sample sizes, and a lack of longitudinal follow-up, making it difficult to generalize findings or establish best practices (eg, [34,35]). As prenatal care becomes increasingly hybrid and digitally mediated, particularly after the COVID-19 pandemic, it is essential to understand how, when, and for whom XR interventions are most effective, and to identify key design and implementation features.

Aim of the Review

This scoping review aims to explore and map the evidence on the application of immersive technologies in prenatal course programs, focusing on their benefits, challenges, and potential for enhancing learning and emotional preparedness among expectant parents. By synthesizing key findings and trends, the review aims to inform educators, clinicians, designers, policymakers, and researchers. It supports evidence-informed use of immersive technologies to improve maternal and perinatal outcomes and fosters a shared understanding of the state of the art and next research steps in partnership with stakeholders involved in childbirth preparation. This scoping review begins with a comprehensive search of academic peer-reviewed literature. By grounding the review in scientifically validated evidence, it lays a basis for later examining broader practical implications and innovations within the gray literature. The following key research questions (RQs) guided the search strategy and data extraction process in the academic literature:

- RQ1: what are the primary applications of virtual, augmented, mixed, and immersive technologies in prenatal education programs?
- RQ2: what benefits have been reported regarding their use in enhancing learning, emotional preparedness, and engagement?
- RQ3: what challenges and limitations are identified in implementing XR-based interventions in prenatal education?
- RQ4: what methodologies and technological approaches are most used in studies on XR in prenatal education?
- RQ5: what research gaps exist in this area, and what future directions are recommended?

The findings will provide a thorough overview of how XR is used in prenatal education, offering insights for researchers, educators, and policymakers on effectively integrating innovative technologies to enhance maternal health outcomes.

Methods

Study Design

This scoping review followed a five-step process: (1) formulating the research question, (2) identifying relevant studies, (3) selecting studies for inclusion, (4) organizing the data, and (5) synthesizing and presenting the findings [36]. The final search strategy was refined through an iterative approach to optimize database searches and improve search terms. To ensure methodological rigor and clarity, the study design and manuscript preparation adhered to the PRISMA-ScR (Preferred Reporting Items for Systematic Reviews and Meta-Analyses extension for Scoping Reviews) framework [36,37].

A scoping review was chosen to provide an overview of the available evidence, not a formal critical synthesis or a definitive answer to a specific research question [38].

Protocol and Registration

The scoping review protocol is registered a priori with the Center for Open Science (OSF; registration type: OSF Preregistration, date registered: March 5, 2025 [39]).

Selection of Sources of Evidence and Eligibility Criteria

The selection of evidence sources was conducted in 4 sequential and distinct phases: “First Round,” “Second Round,” “References Inclusion Round,” and “Third Round” (Table 1). To systematically identify a comprehensive set of papers that contribute to addressing our research questions, we established a set of eligibility criteria to be applied iteratively through several rounds. The criteria aim to minimize false negatives and false positives, ensuring that only studies meeting the defined standards are included in the review. Table 1 provides an overview of the criteria used to filter and select the studies.

XSL•FO
RenderX

Table . Description of the eligibility criteria.

Selection sources phase	Eligibility criteria applied
First round	• Inclusion criteria • Original papers published in English. • Articles published in peer-reviewed journals or credible conference proceedings. • Focused on the use of XR[a] technologies (VR[b], AR[c], MR[d], or 360° video) in prenatal or childbirth education for pregnant women and expectant parents. • Addressed outcomes such as learning, emotional preparedness, anxiety reduction, or partner engagement. • Involved expectant parents and/or stakeholders. • Exclusion criteria • Non–English-language • Article types: book, book chapters, dissertations, abstracts, posters, interviews, protocols, and reports. • Nonoriginal articles: meta-analysis and reviews, including reviews without original data or studies with insufficient detail. • No full text available. • Not focused on prenatal or childbirth education for parents. • Addressed XR in clinical obstetric care but not in an educational context. • Studies primarily describing XR-based training for health care professionals or clinical skills education. • Studies based solely on remote learning, online courses, or mobile messaging without immersive interaction.
Second round	• Exclusion criteria • Studies without participants. • The article does not report any qualitative or quantitative participant involvement results.
References inclusion round	• This step focused on identifying additional studies by screening the reference lists of the previously included papers.
Third round	• This phase consisted of an additional verification of all previously screened files to ensure consistency and completeness. Furthermore, we extended the search to include the SciSpace database, which allowed us to identify and incorporate additional relevant papers not captured in earlier rounds.

[a]XR: extended reality.

[b]VR: virtual reality.

[c]AR: augmented reality.

[d]MR: mixed reality.

Information Sources and Search Strategy

A comprehensive search strategy was developed to identify relevant literature on the use of XR in prenatal education. The search process included both database searches and gray literature exploration to ensure thorough coverage of the topic.

The search was conducted from January 30 to October 16, 2025. To ensure comprehensive coverage across health sciences, psychology, and technology, the following databases were systematically searched:

1. APA PsycArticles and APA PsycINFO: capture psychological and behavioral science research, including mental health, anxiety, and parental preparedness relevant to prenatal education.
2. PubMed: offers broad biomedical coverage, including maternal health, obstetrics, and digital health, making it critical for identifying studies on physiological and emotional outcomes.
3. Web of Science (WoS), Cumulative Index to Nursing and Allied Health Literature (CINAHL)**,** and Scopus**:** provide wide-reaching coverage of peer-reviewed, multidisciplinary research, ensuring inclusion of various study designs (eg, RCTs and pilot studies).
4. IEEE Xplore: specializes in technology and human-computer interaction (HCI), essential for identifying studies on VR systems, usability, and digital learning tools.

The gray literature was explored using the following sources: Google Scholar**,** WHO Reproductive Health Library, and SciSpace.

XSL•FO
RenderX

The search strategy combined three main concept blocks: (1) immersive technologies ("virtual reality," "augmented reality," "mixed reality," "extended reality," and "immersive technology"); (2) prenatal and childbirth education ("prenatal education," "antenatal education," "childbirth education," "prenatal classes," "parenting classes," "expectant parent education," and "childbirth training"); and (3) participant and facilitator roles ("pregnant women," "expectant parents," "midwife," "childbirth educator," "parent educator," "perinatal educator," "healthcare provider," and "health professional").

Boolean operators ("AND"/"OR"/"NOT") were applied appropriately, and syntax was adapted to each database (PubMed, Scopus, Web of Science, IEEE Xplore, CINAHL Ultimate, APA PsycINFO, and APA PsycArticles). The final search was rerun on October 16, 2025, and full database-specific queries are reported in Multimedia Appendix 1. Studies focusing exclusively on professional training, without a direct patient-facing component, were excluded. This approach balances inclusivity in the initial search with relevance during study selection, helping to identify interventions co-designed or delivered by professionals but intended for parents. The search strategy, including the keywords and search strings used, is summarized in Table 1. The research team supplemented the sources identification process by including references cited within the full texts of publications included as a result of the database search. This approach was guided by the selection strategy detailed in the PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) 2020 flow diagram (Figure 1).

Data Items

For each included study, we extracted the following variables: (1) bibliographic information: authors, year of publication, country, and journal or conference; (2) study characteristics: design (eg, RCT, quasi-experimental, and qualitative), setting (hospital, university, and online), and sample size; (3) participant characteristics: demographics (age, sex, and gestational stage), inclusion of partners or caregivers, and specific eligibility criteria; (4) intervention details: type of VR technology (eg, immersive headset, 360° video, and mobile app), educational content (childbirth, breastfeeding, prenatal exercise, and mental health), frequency, and duration of sessions; (5) comparator (if applicable): conventional prenatal education, standard care, or no intervention; (6) outcomes: (a) psychological features and symptoms (anxiety, depression, fear of childbirth, and perceived stress); (b) physiological during intrapartum and postpartum outcomes (pain, uterine activity, perineal trauma, and postpartum hemorrhage); (c) educational outcomes (knowledge acquisition, memory retention, and preparedness); and (d) user experience outcomes: usability, satisfaction, immersion, and engagement; (6) main results: direction of outcomes, qualitative themes, and feasibility and acceptability measures; and (7) other relevant information: inclusion of partner or family support, equity considerations (digital literacy and access), and reported methodological limitations (Tables 2-6).

Table . General information summaries of selected studies.

References	Database	Country	Study design	Background	Objectives
Xie and Zeng [23]	PubMed	China	Randomized clinical trial with a 2-group intervention design	• With the implementation of the 2-child policy in China, childbirth rates have increased. Many women experience fear and anxiety about childbirth, which can prolong labor and increase complications. VR[a] has been increasingly used in health care settings, offering immersive and interactive experiences. This study investigates the effectiveness of VR combined with moderate perineal protection during childbirth.	• To explore the effects of VR-based prenatal health education combined with moderate perineal protection on childbirth outcomes, pain management, self-efficacy, anxiety, and perineal trauma in primiparous women.
Lee et al [34]	Google Scholar	Korea	Prospective interventional study	• Pregnant women face significant physiological and psychological changes, increasing the risk of mental health disorders, including depression and anxiety. • Mental health disorders in pregnancy can negatively impact both the mother and infant, increasing risks such as low birth weight and preterm birth. Existing mental health programs for pregnant women are insufficient in terms of accessibility and effectiveness.	• To prospectively investigate the efficacy of a VR-assisted mental health promotion program in pregnant women. • To assess its impact on depression, anxiety, perceived stress, and quality of life. • To evaluate the program's effectiveness in high-risk subgroups of pregnant women.

XSL•FO
RenderX

References	Database	Country	Study design	Background	Objectives
Caballero-Galilea et al [40]	Web of Science, Scopus, and PubMed	Spain	Single-group pre-post quasi-experimental study based on the Transparent Reporting of Evaluations with Nonrandomized Designs (TREND) guidelines	• Anxiety affects up to 1 in 4 pregnant women and is associated with adverse obstetric, neonatal, and psychological outcomes. FOC[b] occurs in 5% - 15% of cases and contributes to higher cesarean rates and reduced maternal well-being. While traditional prenatal education and psychological interventions can mitigate these effects, evidence on the use of VR for improving mental health and reducing childbirth-related anxiety remains limited but promising.	• To assess the effectiveness of immersive VR exposure to the childbirth process in reducing anxiety among women in the third trimester of pregnancy.
Siivola et al [41]	CINAHL Ultimate, PubMed, and Google Scholar	Finland	Pilot study with a user-centered design process	• The COVID-19 pandemic led to the cancellation or transition of CBE[c] to online formats in Finland. There was a need for an alternative method to provide immersive and engaging CBE. FOC has been increasing in Finland, necessitating better education tools.	• To develop a VR childbirth education program with 360° videos. • To test the program's usability, motion sickness, effectiveness, and potential impact on FOC. • To investigate which end-user devices are preferred (eg, VR headset, computer, tablet, and smartphone). • To make CBE accessible across multiple devices, including VR headsets, computers, tablets, and smartphones.
Siivola et al [42]	Scopus and Google Scholar	Finland	User-centered design study		• To evaluate the effectiveness of a VR CBE program in improving learning outcomes, usability, and user experience, while also assessing its impact on FOC.

XSL•FO
RenderX

References	Database	Country	Study design	Background	Objectives
				• CBE in Finland has deteriorated, with many expectant parents lacking access to hospital tours or comprehensive prenatal education. VR presents an opportunity to enhance CBE by offering immersive and realistic childbirth experiences.	
Tang et al [43]	IEEE Xplore	Belgium	Qualitative user study	• Breastfeeding has well-documented health benefits, yet many new parents face difficulties during the early postnatal stage. Traditional antenatal education often fails to convey the complexity of real-life breastfeeding experiences. VR has the potential to provide an immersive and interactive way for parents-to-be to explore these challenges.	• To assess the potential of a VR breastfeeding simulation ("Virtual Feed") in conveying the lived experience of breastfeeding and to explore user expectations related to playful technology in health care.
Tang et al [44]	Scopus, Web of Science, and Google Scholar	Belgium (participants from various backgrounds including Western, Eastern, and Southern Europe, as well as South and Southeast Asia)	Qualitative co-design	• Breastfeeding offers numerous benefits but remains challenging for many parents. Antenatal education often presents breastfeeding as a natural and straightforward process, which can lead to unrealistic expectations. • The study aimed to address this gap by designing an immersive VR breastfeeding simulation to help parents experience common breastfeeding challenges.	The study sought to answer 2 primary research questions: • What design considerations are needed to create interactive simulations for breastfeeding experiences? • How do parents and parents-to-be perceive such simulations, and what is their potential in antenatal education?
Noben et al [45]	Google Scholar	Netherlands	Randomized controlled trial		

XSL•FO
RenderX

References	Database	Country	Study design	Background	Objectives
				• Previous research demonstrated that the level of anxiety and FOC is known to be associated with the incidence of postpartum depression. Women who deliver by a CD[d] are at risk for both increased fear of childbirth and postpartum depression. It is essential to minimize preoperative anxiety for these patients because lower preoperative anxiety has been shown to lead to greater maternal satisfaction with CD and thus a more positive birth experience.	• To investigate the effect of VR in addition to conventional information provision on the preoperative anxiety levels of women undergoing a planned CD.
Setiawan et al [46]	Google Scholar	Indonesia	Pilot feasibility study; Semiexperimental study	• There are still many pregnant women who are less interested in exercising during pregnancy, due to heavy workload during the working day and a dense schedule of daily activities in her career or as a housewife. Some women assume that attending a pregnancy exercise course in hospitals or health care centers is time-consuming and too formal because they have to follow the prenatal personal trainer schedule. The technology that allows helping pregnant women in exercise during pregnancy is virtual reality.	• To develop a VR app for pregnant women to easily perform an exercise during pregnancy with no limited space and time.
Park and Kim [47]	Google Scholar	Korea	Quasi-experimental study

References	Database	Country	Study design	Background	Objectives
				• Hospitalized women with threatened preterm labor often experience psychological and physical distress, which may exacerbate uterine activity and cervical changes, necessitating targeted prenatal care. VR-based prenatal education may improve engagement and support. Guided by the Cox IMCHB[e], this study developed and evaluated a VR prenatal education program to address these complex needs.	• To design, administer, and assess the impact of a VR-based prenatal education program for pregnant women hospitalized due to preterm labor.
Montoya-Moncada et al [48]	PubMed	Colombia	Noninferiority randomized controlled trial		• To test whether mixed reality + standard counseling improves maternal self-efficacy (BSES-SF) and satisfaction (MBFES) versus standard counseling alone, 1 week post partum.

XSL•FO
RenderX

References	Database	Country	Study design	Background	Objectives
				• Breastfeeding is natural but requires learned skills and is shaped by social and psychological factors. The World Health Organization and the United Nations Children's Fund recommend 6 months of exclusive breastfeeding and continued breastfeeding with complementary foods for at least 2 years, yet rates remain low worldwide. Traditional counseling is mostly theoretical and rarely uses modern technology; motivation and confidence help success, while stigma, aggressive formula marketing, and poor guidance hinder it. This study tests whether a mixed-reality educational approach, compared with standard counseling, improves mothers' satisfaction and confidence.

Table . Demographic characteristics of participants in the experiments.

Study (year)	Single or multicenter	Inclusion and exclusion criteria	Recruitment methods	Sample size	Sex, n (%)	Age (years)[a]
Xie and Zeng [23] (2023)	Single center	Inclusion criteria: (1) singleton full-term pregnancy, (2) normal external pelvic measurement, (3) no obvious cephalopelvic disproportion, (4) no complications during pregnancy or labor, and (5) age 20 - 34 years. Exclusion criteria: (1) estimated fetal weight≥4000 g, (2) fetal biparietal diameter>9.7 cm, (3) presence of mental illness or communication disorders, and (4) use of analgesia during labor.	Pregnant women receiving routine antenatal care at the hospital between June 1, 2018 and December 31, 2018, were invited to participate. Participants and their families provided informed consent before enrollment.	N=200: primiparous women were randomly assigned to either the treatment group (n=100) or the control group (n=100).	Female=200 (100%)	Treatment group: 30.29 (1.14) Control group: 30.35 (1.07)

XSL•FO
RenderX

Study (year)	Single or multicenter	Inclusion and exclusion criteria	Recruitment methods	Sample size	Sex, n (%)	Age (years)[a]
Lee et al [34] (2025)	Single center	Inclusion criteria: (1) pregnant women, (2) able to understand and use the Korean language, and (3) willing to participate in the study. Exclusion criteria: (1) intellectual disability preventing VR[b] training, (2) visual impairment making VR use impossible, and (3) illiteracy.	Advertisements in the obstetrics and gynecology unit.	N=56 (participants were grouped using cluster analysis based on their mental health characteristics before the VR intervention. The study identified three clusters: (1) Cluster 1 (Healthy Mental State): 19 (33.9%) participants with low depression and anxiety. Higher quality of life. No significant need for intervention. Cluster 2 (Treatment-Required Group—High-Risk): 9 (16.1%) participants with high depression and anxiety scores. Low quality of life. Required active mental health support. Cluster 3 (Intermediate Group): 28 (50%) participants with moderate depression and anxiety. NB: High-risk participants were also defined using standard clinical cutoff scores: (1) PHQ-9[c] cutoff for depression:≥8; (2) GAD-7[d] cutoff for anxiety:≥5. From this, two additional high-risk groups were analyzed separately: (1) high-risk for depression (PHQ-9≥8); n=20 (35.7%); (2) high-risk for anxiety (GAD-7≥5); n=8 (14.3%).	Female=56 (100%).	34.3 (4.0)

Table . Characteristics of experimental methodology.

Study	Experimental procedure	Health operator involvement	Measures	Variables investigated
Xie and Zeng [23]	• Treatment group: prenatal education with VR[a]-based health education. • Control group: traditional prenatal education.	• Midwives trained in moderate perineal protection. • Nursing staff provided VR-based health education.	• Delivery outcomes: time of second-stage labor, postpartum hemorrhage within 2 hours, neonatal Apgar scores, and neonatal weight. • Pain levels: VAS[b] (0 - 10). • Anxiety levels: VAS-A. • Self-efficacy: general Self-Efficacy Scale. • Quality of life satisfaction: self-reported scale (0 - 100).	• Pain. • Anxiety. • Delivery outcomes (labor duration, hemorrhage, and perineal trauma). • Self-efficacy and quality of life.

Lee et al [34]	• Experimental procedure: VR-assisted mental health promotion program designed specifically for pregnant women.	• Health care professionals were involved in the recruitment process and monitoring participant safety.
		  • VR procedure was self-administered
		  • Assessment and monitoring: the mental health state of participants was assessed before and after the VR intervention using self-reported measures.
			• Standardized scales and questionnaires:
			  • PHQ-9[c]
			  • GAD-7[d]
			  • PSS[e]
			  • WHOQOL-BREF[f]
				• Depressive and anxiety symptoms.
				• Stress-related symptoms
				• Quality of life.

Caballero-Galilea et al [40]	• Participants experienced a 60-min immersive VR simulation of eutocic childbirth after standard education. Anxiety (PRAQ-20[g]) was assessed pre- and postintervention.	• Developed and supervised by midwives and obstetricians, midwives facilitated sessions and ensured participant safety during the VR simulation.	• Pregnancy-Related Anxiety Questionnaire–Revised (PRAQ-20) administered pre and post VR; sociodemographic and obstetric data collected.	• Pregnancy-related anxiety • VR adverse effects.

Study	Experimental procedure	Health operator involvement	Measures	Variables investigated
Siivola et al [41]	• Participants used VR headsets and other devices to test the childbirth education program.	• The project involved midwives, childbirth educators, and researchers. • A real midwife played the role in the videos to ensure authenticity.	• Pretest Questionnaire: a structured online questionnaire was administered before participants engaged with the VR program. • During the VR experience, observational measures, and a cognitive walkthrough were conducted to assess usability. • After the VR experience: semistructured interview to gain qualitative feedback. • Posttest Questionnaire: to evaluate their experiences. • Usability and interaction tracking (during home use phase).	• Usability of the VR program. • Motion sickness occurrence. • User preference for different devices. • Impact on FOC[h]. • Variables measured: • Demographics: name, age, number of previous births, last childbirth year, current pregnancy status. • Previous childbirth education exposure: participation in childbirth education (CBE) at a public prenatal clinic, attendance at a hospital birth ward tour, enrollment in additional childbirth education classes • Preferred learning methods for childbirth. • FOC history • Experience with virtual reality. • Engagement with the VR program. • Motion sickness symptoms. • Usability and learning curve. • Time spent in the VR experience. • Duration of headset use. • Physical comfort. • Device preference. • Perceived value of VR components. • Effectiveness of different media formats in learning. • Impact on fear of childbirth.
Siivola et al [42]	• Participants used the VR childbirth education program with a headset under researcher observation.	• A Lamaze-certified childbirth educator was involved in study design, data analysis, and participant support.	• Usability: PSUS[i] • Engagement: observational data on VR session length and content consumption • Learning outcomes: self-reported understanding of childbirth-related topics. • Emotional impact: FOC	User engagement and experience with VR childbirth education. Usability of the VR program Improvement in childbirth knowledge and preparedness. Impact on FOC.
Tang et al [43]	• Participants engaged with the VirtualFeed VR breastfeeding simulation.	• None reported; study focused on self-guided user experiences.		User perceptions of breastfeeding simulation realism. Impact of interactivity and game-like elements. Potential application of VR for antenatal education.

XSL•FO
RenderX

Study	Experimental procedure	Health operator involvement	Measures	Variables investigated
			• Qualitative thematic analysis of interview transcripts. • User feedback on realism, effectiveness, and engagement with the simulation.	
Tang et al [44]	Participants engaged in (1) visualizing and discussing breastfeeding settings; (2) exploring challenges and social influences on breastfeeding; (3) expressing design preferences for the VR environment; and (4) describing ideal and challenging breastfeeding scenarios.	• The study did not involve direct medical professionals.	• Thematic analysis of participant responses. • Visual and interactive engagement through VR and design workshops. • Reflections on breastfeeding experiences based on user feedback.	User perception of the breastfeeding simulation Immersion and realism of the VR experience Potential impact on antenatal education Challenges and facilitators of breastfeeding.
Noben et al [45]	• VR group: VR video was shown using the Infor-Med app on the participant's smartphone, and VR glasses were supplied by the researcher at the outpatient clinic.	• Physician and researcher	• Anxiety: VAS-A. • Simulation Sickness: SSQ[j]. • Tilburg Pregnancy Distress Scale. • Childbirth Perception Scale (CPS). • Pregnancy and Childbirth Questionnaire (PCQ).	Preoperative anxiety, motion sickness symptoms, woman's perception of her pregnancy, perception of delivery and perception of the first postpartum week, preoperative information, participants in the VR group received an additional question if they felt more prepared for CD after seeing the VR video.
Setiawan et al [46]	• Doing vital sign check-up to the target user before practice with VR. • VR application implementation for the target user. • Doing a vital sign check-up after practice with VR and evaluation of the IVE[k] questionnaire.	• None reported.	• Simulator Sickness Questionnaire, User experience in the IVE.	Vital signs: heart rate (HR), blood pressure (BP), respiration rate (RR), and anemic conjunctiva (AC). Symptoms like vomiting, nausea, and dizziness.
Park and Kim [47]	• VR Group: 3 VR sessions. • Components: educational VR program and relaxation meditation VR. • Control Group: received usual care only without VR.	• 1 VR expert, 1 nursing professor, and 1 head nurse from a women's specialty hospital.	• Self-report questionnaire: STAI[l]. • Stress related to preterm labor. • Pregnancy health care practice behavior. • Self-efficacy in pregnancy health care. • Uterine contractions: frequency (times/min) and intensity (mm Hg). • Cervical length: transvaginal ultrasound.	State anxiety, stress related to preterm labor, frequency and intensity of uterine contractions, cervical length, practice behaviors in pregnancy health care, self-efficacy in health care.
Montoya-Moncada et al [48]		• Trained nurses, nursing assistants, and general practitioners delivered and facilitated sessions and provided real-time feedback.		Group assignment (MR+ standard vs standard) → maternal self-efficacy, maternal satisfaction, and EBF at 1 week.

Table . Results, conclusion, and implications for future research.

Study	Results	Conclusions	Implications for future research
Xie and Zeng [23]	• No significant difference in second-stage labor duration between groups. • The treatment group had significantly lower postpartum hemorrhage (151.28 mL vs 248.95 mL; *P*=.008). • Pain scores were significantly lower in the treatment group (3.73±1.87 vs 5.97±2.66; *P*<.05). • No significant effect on neonatal Apgar scores or weight. • The treatment group had a higher rate of intact perineum and lower rates of severe perineal lacerations (*P*<.05). • Anxiety scores were significantly lower in the treatment group during labor (*P*<.001). • Self-efficacy and quality of life satisfaction were significantly higher in the treatment group (*P*<.001).	• VR[a] technology combined with moderate perineal protection can improve childbirth outcomes by reducing pain, anxiety, and perineal trauma. • This approach increases maternal confidence and promotes a better childbirth experience without adverse effects on newborns. • The intervention can be widely applied in clinical obstetric settings.	• Further studies should use standardized psychological scales to assess maternal mental health. • Future research should evaluate long-term maternal and neonatal outcomes. • Expanding VR health education to other aspects of maternal care, such as postpartum recovery, may be beneficial.
Lee et al [34]	• Significant reduction of depressive and anxiety symptoms comparing before and after VR program. • Quality of life scores significantly increased. • No significant change in perceived stress scores. • The program was particularly effective in the high-risk subgroup with severe depression and anxiety.	• The VR intervention was most effective for Cluster 2, which had the most severe mental health issues. • Depression, anxiety, and quality of life improved significantly in the high-risk depression group (PHQ-9[b]≥8). • Participants with high anxiety (GAD-7[c]≥5) showed improvements, but they were not statistically significant. • Perceived stress did not improve significantly in any of the high-risk groups.	• Future studies should customize VR interventions for specific high-risk subgroups. • A longer intervention period (more than 5 weeks) may be needed to show stronger effects. • VR programs should incorporate stress management techniques to improve perceived stress outcomes.
Caballero-Galilea et al [40]	• Significant postintervention decreases in PRAQ-20[d] anxiety scores (*P*<.001); greater effect among younger and primiparous women; no adverse effects; participants reported increased confidence and preparedness.	• Immersive VR childbirth simulation effectively reduced pregnancy-related anxiety, was well-tolerated, and perceived as supportive; results support VR as a complement to traditional prenatal education.	• Recommend RCTs[e] and longitudinal studies to confirm effects, assess long-term outcomes, explore emotional mechanisms, and adapt VR childbirth education for diverse populations.
Siivola et al [41]	• Users successfully navigated the VR program with minimal instructions. • No motion sickness was reported. • Users preferred using the program on personal devices rather than in research settings. The program was perceived as effective for childbirth education. Some improvements were suggested, such as adjusting camera angles and adding more immersive birth sequences.	• The VR CBE[f] program was well received and demonstrated potential for improving childbirth education. • It provided a realistic and immersive experience, making learning more engaging. • Further studies are needed to assess its impact on reducing FOC[g].	• Future studies should test the VR CBE with pregnant women and individuals diagnosed with FOC. • Evaluating the effectiveness of VR-based learning in improving childbirth preparedness. • Exploring further enhancements, such as interactive VR environments.

XSL•FO
RenderX

Study	Results	Conclusions	Implications for future research
Siivola et al [42]	• Users watched an average of 33 minutes of VR content. 4/5 participants watched all 18 videos; one skipped a few due to prior knowledge. Usability scores were high (87 for VR and 76 for independent testing). VR improved learning outcomes compared to traditional CBE. Fear of childbirth impact varied; one participant's FOC increased, while another's FOC decreased.	• VR CBE provided a realistic, immersive learning experience. • The program was well-received, particularly for first-time parents.	• Testing with a larger and more diverse sample. Expanding VR content to include more childbirth scenarios (eg, medical pain relief and home births). • Investigating long-term retention of knowledge gained through VR CBE.
Tang et al [43]	• Participants found the simulation engaging and realistic. The simulated baby's behavior (delayed latching and hunger cues) effectively conveyed real breastfeeding challenges. Some participants felt frustrated by the lack of clear guidance and suggested integrating more explicit game elements, such as tutorial instructions and achievement notifications. The simulation was seen as a valuable tool for antenatal education, facilitating discussions between parents and health care providers.	• VR can effectively simulate breastfeeding challenges, promoting awareness and reflection. Participants expected game-like elements within the VR environment, raising questions about balancing realism and usability in health care simulations. The lack of explicit feedback within the simulation led to user frustration, suggesting the need for guided interactions.	• Investigate the optimal balance between realism and playfulness in VR health care simulations. Explore the impact of gamification on learning outcomes in antenatal education. • Assess the long-term effectiveness of VR breastfeeding simulations in improving breastfeeding success rates.

Tang et al [44]		• VR breastfeeding simulations can enhance antenatal education by providing immersive, realistic experiences.
		• The study highlighted challenges in VR design, such as managing uncertainty, realism, and user expectations.
		• In summary, the study's results indicate that interactive VR simulations can effectively communicate the complexities of breastfeeding by combining emotional engagement with experiential learning. Rather than providing explicit instruction, such systems may be most impactful when they offer opportunities for introspection and encourage users to reframe their expectations. The findings underscore the importance of designing with empathy, realism, and flexibility in mind—particularly when addressing sensitive and deeply personal aspects of early parenthood.
			• Future work should explore:
			  • Customization options to reflect diverse family structures and breastfeeding experiences.
			  • Incorporation of haptic feedback to simulate the physical aspects of breastfeeding.
			  • Longitudinal studies on the impact of VR simulations on breastfeeding success.

XSL•FO
RenderX

Study	Results	Conclusions	Implications for future research
	• Thematic analysis revealed 2 dominant themes. The first theme highlighted the emotional and logistical imbalance often present in breastfeeding relationships, where one parent typically assumes the feeding role while the partner provides indirect support. Participants frequently emphasized the importance of practical and emotional presence from partners, such as preparing food, staying close during night feeds, or simply offering words of encouragement. • The second theme focused on parents' evolving understanding of breastfeeding. Many participants described the initial stages as marked by uncertainty, technical difficulties, and emotional strain. Public breastfeeding emerged as a significant source of stress, with participants reporting a lack of appropriate facilities and discomfort associated with social exposure. Nevertheless, some individuals reported that prior exposure to breastfeeding scenes, such as observing siblings or relatives breastfeed, had helped normalize the practice and reduced their own discomfort. • Participants expressed preferences for visually clean, aesthetically pleasing environments rendered in high-fidelity 3D graphics, along with gender-neutral color palettes and customizable avatars. Furthermore, they emphasized the value of including realistic but non-overwhelming challenges within the simulation. • Based on these findings, the researchers refined the VR simulation in the third phase. The updated version included 3 scenarios: breastfeeding in a home setting with a partner present, a public park environment populated with distant nonplayer characters and background noise, and a workplace scenario simulating a return to work, with social pressure and unexpected interruptions. The virtual baby was also redesigned to incorporate feeding behaviors, latching mechanics, and emotional states, represented through facial expressions and audio cues. A 9-state behavior model		

XSL•FO
RenderX

Study	Results	Conclusions	Implications for future research
	was implemented to simulate the unpredictability of infant behavior during feeding. Thematic analysis of the interview transcripts revealed 2 overarching themes. The first described participants' deep affective engagement with the simulation. Many users, especially those with prior breastfeeding experience, reported that the simulation closely mirrored their own lived realities, triggering emotional recall, moments of joy and frustration, and a sense of bonding with the virtual baby. • The second theme referred to aspects of the simulation that disrupted immersion. These frictions stemmed from mismatches between the users' bodies and their virtual avatars, insufficient interactivity with nonplayer characters, overly pristine environments that did not reflect the reality of a household with a newborn, and the absence of tactile or haptic feedback. Additionally, several participants indicated a desire for more explicit feedback mechanisms, such as prompts or tutorials, to guide them through the feeding process. The simulation was generally perceived as nonthreatening and emotionally safe. None of the participants reported feeling discouraged or overwhelmed; rather, the VR experience facilitated nuanced reflection on breastfeeding and helped both parents and partners consider their roles more deeply.		
Noben et al [45]		• The study did not show a decrease in preoperative anxiety after VR information provision for patients undergoing elective CD. There was a trend toward decreased preoperative anxiety in the subgroup of women with a history of emergency CD who watched the VR video.	• Further research for identifying the characteristics of subgroups of patients who would potentially benefit from VR information provision is necessary.

XSL•FO
RenderX

Study	Results	Conclusions	Implications for future research
	• There was an increase in the Visual Analog Scale for Anxiety (VAS-A) score between the first and second measurements of 1.5 cm for the women in the VR group compared to 0.8 cm for women in the control group (95% CI −0.1 to 2.0; *P*=.08). For their partners, there was an increase of 1.4 cm in the VR group compared to 0.9 cm in the control group (95% CI −0.5 to 1.6; *P*=.30). • The following variables showed a significant relation with ΔVAS-A: baseline VAS-A ($F_{1,75}$=8.4; *P*=.01) and history of CD[h] ($F_{1,75}$=6.0; *P*=.02). The increase in the baseline VAS-A score at time point 2 (at admission) in women in the VR group with a history of emergency CD was 1.7 cm smaller than that in women with a history of emergency CD in the control group, although this effect was not significant (*P*=.06). • Median scores on the SSQ[i] for motion sickness symptoms reflected the absence of discomfort caused by the VR video. • There was no significant difference in scores on the Tilburg Pregnancy Distress Scale subscales for both time points 1 and 2 between the VR group and the control group. • Individuals in the VR group without a history of emergency CD perceived a higher quality of care than the control group (10.2, SD 3.8 vs 12.9, SD 3.5; *P*=.02). 15% of women responded that they did not feel more prepared after seeing the VR video. 85% of women responded positively. From the partners, 79% responded positively. The 21% partners did not feel more prepared after seeing the VR video.		
Setiawan et al [46]	• The results of checking the vital signs after doing exercise with VR showed no sign of bad health conditions. • The average of all aspects of the IVE[j] questionnaire given is 4.26. (max 5)	• The average results of all aspects of the components in the IVE questionnaire showed positive results. That indicates the VR application for pregnancy exercise is feasible to use by pregnant women.	• In future research, it is possible to develop mixed reality applications for pregnancy exercise so that when doing exercise, pregnant women can still see the environment in the real world.
Park and Kim [47]

Study	Results	Conclusions	Implications for future research
	• State Anxiety: Experimental group: mean 44.53 (SD 7.58); Control group: mean 52.93 (SD 8.96); *P*=.009. VR intervention significantly reduced anxiety levels. • Stress Related to Preterm Labor: Experimental group: mean 48.66 (SD 4.82); Control group: mean = 55.87 (SD 6.91); *P*=.002. VR education significantly lowered stress scores. • Uterine contractions: frequency (times/min): Experimental: 1.00 (SD 0.75); Control: 1.84 (SD 0.76); *P*=.004. • Intensity (mm Hg): Experimental: 10.13 (SD 3.97); Control: 23.43 (SD 10.11); *P*<.001. Significant reductions in both frequency and strength of uterine contractions in the experimental group. • Cervical length: Experimental group: 33.93 (SD 5.33) mm; Control group: 31.62 (SD 7.38) mm; *P*=.009. Cervical length increased more in the experimental group, indicating a possible delay in labor progression. • Pregnancy health care practice behavior: Experimental group: 71.60 (SD 5.86); Control group: 67.37 (SD 5.47); *P*=.047; improved health-promoting behaviors in the experimental group. • Self-efficacy in pregnancy health care: Experimental group: 46.93 (SD 2.93); Control group: 40.81 (SD 4.98); *P*=.001. Higher confidence in managing pregnancy in the VR group.	• The VR-based prenatal education program was statistically and clinically effective in improving: • Psychological well-being (reduced anxiety and stress). • Physiological indicators (lower uterine activity and increased cervical length). • Behavioral outcomes (better self-care practices and self-efficacy).	• Future studies should: • Replicate the intervention across multiple institutions, diverse geographic areas, and larger sample sizes to confirm its effectiveness and improve external validity. • Use RCTs to strengthen causal inferences and minimize confounding factors. • Explore personalized VR content tailored to clinical severity (eg, cervical length, prior preterm labor) and educational needs. • Involve interdisciplinary collaborations (eg, obstetrics, psychology, digital health, and user experience design) to enhance both content relevance and technological usability. • Assess the sustained impact of VR-based education on: preterm birth rates, neonatal outcomes, maternal mental health postpartum, and long-term health behavior adherence. • Examine: barriers to use (eg, motion sickness and device usability); user interface improvements; low-cost and mobile-accessible versions for wider clinical implementation. • Include mediator and moderator analysis to isolate which components of the intervention are most impactful.
Montoya-Moncada et al [48]	• No between-group differences (BSES-SF[k] mean 63.31 vs 63.10; *P*=.87; MBFES[l] 133.48 vs 134.03; *P*=.84). Overall EBF[m] at 1 week = 93.1%; distribution by arm 50%/50%.	• MR adjunct not superior within 1-week window; very high early EBF suggests strong baseline supports.	• Larger samples, multiple sessions, longer follow-up; assess usability and accessibility and consider integration with postnatal supports.

Table . Hardware and software equipment and virtual reality content.

Study	Hardware and software equipment	Virtual reality contents
Xie and Zeng [23]	• Hardware: desktop VR[a] system. • Software: SpaceMax VR software for interactive 3D labor room simulation.	• 3D interactive virtual labor room environment. • Virtual scenarios of delivery processes and perineal protection techniques. Realistic depictions of hospital settings, medical staff interactions, and childbirth procedures.
Lee et al [34]	• No specific details provided, but VR technology was used to create an immersive training and mental health promotion program.	• The VR program included 4 modules: • Module 1: Game-Based Cognitive Training. • Module 2: Advanced Game-Based Challenge. • Module 3: Psychoeducation and Emotional Support. • Module 4: Memory and Anticipation Training.
Caballero-Galilea et al [40]	• Hardware: Meta Quest 3 HMD[b]; obstetric props for kinesthetic immersion. • Software: custom Unity 3D simulation of eutocic childbirth with interactive hospital environment and soundscapes.	• Immersive VR simulation of eutocic childbirth in a virtual hospital setting, guiding participants through admission, monitoring, pain management, epidural, active labor, delivery, and immediate postpartum with multisensory cues and gaze-based interaction; aimed at realistically reproducing the childbirth experience, without a structured psychological or anxiety-focused educational component.
Siivola et al [41]	• Hardware: Insta360 Pro camera, Oculus Quest 2 VR headset, and Zoom H6 recorder. • Software: Adobe Premiere Pro, Pano2VR, and HandBrake.	• 360° multimedia childbirth program including panoramic and video-based labor scenarios, supportive audio clips, brief text and image content, and web resources covering the birth environment, pain relief options, labor positions, monitoring, comfort strategies, and birth preferences.
Siivola et al [42]	• Hardware: Oculus Quest 2 VR headset and Insta360Pro camera. • Software: • Editing: Adobe Premiere Pro and HandBrake (for video compression) • VR Development: Pano2VR • Accessibility: hosted on a website accessible via multiple devices (VR headsets, tablets, smartphones, and computers).	• 360° videos depicting hospital environments and birth scenarios. • Audio narration explaining childbirth procedures. • Interactive elements to explore different birthing techniques. • Additional multimedia content (text, images, and sound clips).
Tang et al [43]	• Hardware: Oculus Rift CV1, Leap Motion Controller, and tangible probe representing a baby (tracked using Oculus Touch controllers). • Software: unity-based VR simulation, SDKs from Oculus and Leap Motion, and FABRIK inverse kinematics.	• VR breastfeeding simulation across home, public, and workplace settings, using a self-avatar and responsive virtual baby to practice latching and feeding under realistic social and environmental conditions; interaction was minimally guided and deliberately nongamified to preserve realism.
Tang et al [44]	• Oculus Rift CV1 VR headset. • Oculus Touch controllers. • Leap Motion Controller. • Tangible baby representation (plush dolls weighted to simulate a newborn).	• The simulation included 3 scenarios: • Personal living space: a home setting for private breastfeeding. • Public park: outdoor breastfeeding experience with environmental influences. • Meeting room: breastfeeding in a workplace setting.

Study	Hardware and software equipment	Virtual reality contents
Noben et al [45]	• Informed app and VR glasses	• The 360° VR video shows all the aspects of a CD, including the admission on the ward, the operating room, placement of spinal analgesia, and the birth of the baby when the gynecologist lifts the baby above the sterile environment.
Setiawan et al [46]	• Xiaomi Redmi Note 4 smartphone and VR Shinecon.	• VR prenatal exercise program with a preprogrammed virtual trainer delivering 10 sessions (warm-up, core seated pregnancy exercises, and cool-down) focused on safe stretching, pelvic movements, and breathing for childbirth preparation, with simple head-nod interaction in an immersive natural setting.
Park and Kim [47]	• VR head-mounted display: equipped with finger motion recognition for navigating menus and selecting content without the need for physical controllers. • 360-degree camera.	• VR intervention combining educational modules on preterm labor, prenatal care, symptom monitoring, hospitalization, and discharge with relaxation and meditation sessions using nature-based imagery, breathing guidance, and nurse-led narration to support knowledge, stress reduction, and emotional regulation.
Montoya-Moncada et al [48]	• MR headset; silicone breast model; infant doll; neonatal simulator; immersive video playback via VR Video Player.	• Immersive breastfeeding scenario videos shown via headset as part of the guided session.

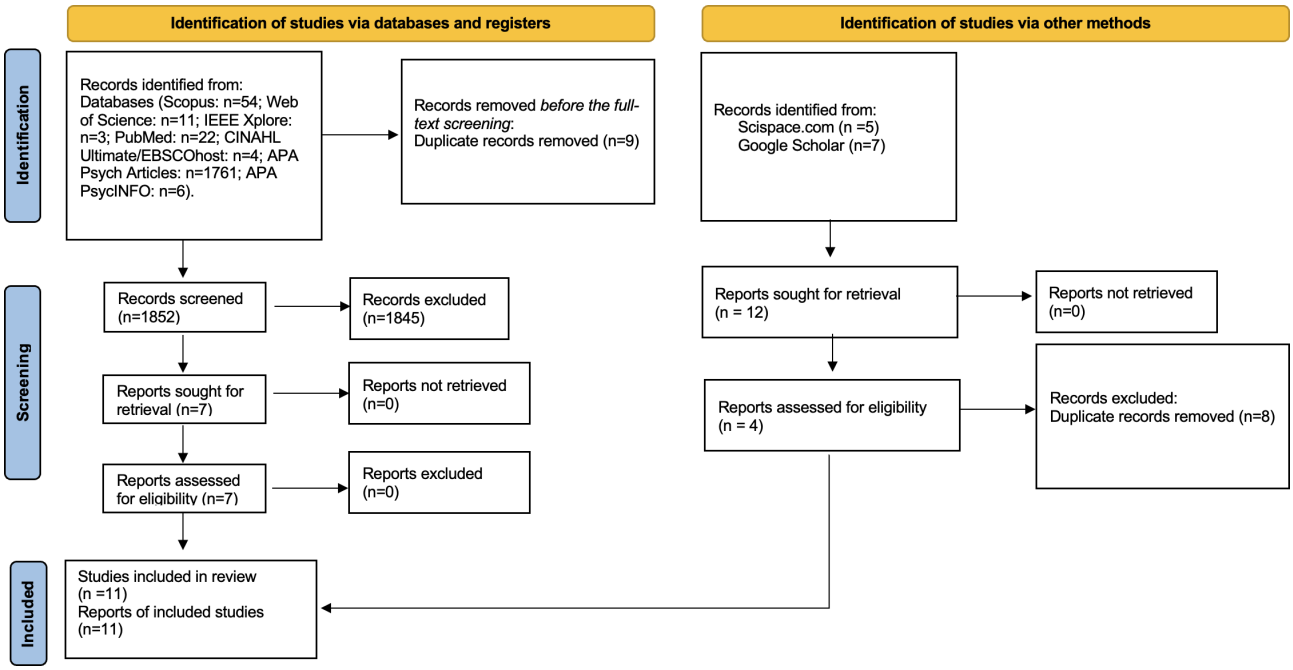
[a]VR: virtual reality.

[b]HMD: head-mounted display.

Data Analysis

We conducted a thematic analysis following Braun and Clarke 6-phase framework [49] to synthesize qualitative and mixed methods insights across the included studies. This approach encompassed the phases of familiarization with the data, generating initial codes, searching for and reviewing themes, defining and naming themes, and producing the final report. Our main objective was to identify patterns related to participant experiences, perceived impacts, and implementation characteristics of XR-based interventions. More specifically, during the familiarization phase, 2 researchers (SP and ONM) thoroughly read the methodology, results, discussion, and conclusion sections of each included study. In the initial coding phase, we systematically labeled and coded relevant segments of the data, identifying features pertinent to our research focus. During the theme generation phase, the coded data were organized into candidate themes. In the reviewing themes phase, we refined and consolidated the themes through an iterative process of comparison, discussion, and evaluation of the coherence and distinctiveness of each theme against the preliminary coded data. Subsequently, in the defining and naming themes phase, we finalized the themes by articulating the scope and content of each one. Finally, in the reporting phase, we described the thematic findings and their relative prevalence across the dataset.

Throughout the analysis, we used an inductive, data-driven approach, allowing the themes to emerge organically from the data without reliance on preexisting theoretical models [50]. In parallel, we complemented this bottom-up strategy with a top-down perspective: the extraction and interpretation of findings were also guided by the research questions formulated during the scoping review process.



Results

Data Charting Process and Data Items

We included 11 studies [23,34,40-48] (Figure 1). A data extraction template has been deployed to outline the relevant data corresponding to the research objectives. The data, recorded either in narrative form or as nominal values, included the variables indicated in Tables 2-6.

XSL•FO
RenderX

Figure 1. PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) 2020 flow diagram for new systematic reviews which included searches of databases, registers, and other sources [51]. Adapted from Page et al [51], which is published under a Creative Commons Attribution 4.0 International License (CC BY 4.0 [52]).

To provide a clearer overview of the findings, the "Results" are structured according to the 5 research questions defined in the "Introduction." Each subsection presents a synthesis of evidence addressing the corresponding question.

RQ1: What Are the Primary Applications of XR in Prenatal Education Programs?

To address RQ1, the included studies were analyzed to identify how virtual, augmented, mixed, and immersive technologies were applied within prenatal, childbirth, and early parenting education. The selected 11 studies included in the final review [23,40-48], from 2019 to 2025, and conducted across 8 countries (China [23], Korea [34,47], Spain [40], Finland [41,42], Belgium [43-45], Netherlands [46], Indonesia [47], and Colombia [48]). The works examined the use of XR technologies, mainly VR and 360° video-based simulations, for prenatal, childbirth, and breastfeeding education, as well as for promoting mental health, relaxation, and physical activity during pregnancy (Table 2). Most studies were single-center and focused on pregnant women as the target population, with 3 studies also involving partners [43-45]. Study designs included RCTs [23,45,48], quasi-experimental or interventional studies [34,40,46,47], pilot or feasibility studies [41,42,46], and qualitative user-centered design investigations [43,44]. Sample sizes ranged from small qualitative cohorts (from 10 to 25 participants) to larger controlled studies (from 60 to 200 participants). From a technological point of view, interventions used a range of immersive solutions: (1) fully immersive VR HMDs such as Oculus Quest, Rift, or equivalent [34,40-47]; (2) 360° or 3D video-based environments accessible through computers or mobile devices [23,41,42]; (3) hybrid setups integrating interactive elements, soundscapes, and guided relaxation content [40,43,47]; and (4) a MR headset used with a silicone breast model and infant doll to simulate breastfeeding [48]. Several studies applied structured instructional or design frameworks such as the Analyze, Design, Develop, Implement, and Evaluate model (ADDIE model) [47] and the IMCHB [47], or used user-centered and co-design methodologies [41-44].

RQ2: What Benefits Have Been Reported Regarding the Use of XR in Prenatal Education?

Overview

The included studies evaluated a range of psychological, physiological, educational, and experiential outcomes: (1) anxiety reduction and mental health promotion [34,40]; (2) childbirth education and fear-of-childbirth management [41,42]; (3) prenatal care for hospitalized or high-risk pregnancies [50]; (4) breastfeeding skill development and experiential learning [43,44,48]; (5) prenatal exercise motivation and maternal physical well-being [46]; (6) pain management and obstetric outcomes during labor [23]; and (7) reduction of preoperative anxiety before cesarean delivery [45]. More in detail, the reported outcomes were categorized into four main domains: (1) psychological outcomes (depression, anxiety, FOC, and perceived stress); (2) physiological outcomes (pain reduction, perineal trauma, postpartum hemorrhage, uterine contractions, and cervical length); (3) educational outcomes (knowledge acquisition, memory retention, and perceived preparedness); and (4) experiential outcomes (user experience, usability, acceptability, and immersion).

Psychological Outcomes

Anxiety reduction was consistently reported across multiple studies. Lee et al [34] conducted a 5-week VR-assisted mental health program for pregnant women, reporting significant reductions in depressive and anxiety symptoms (Patient Health Questionnaire-9 [PHQ-9] and Generalized Anxiety Disorder-7 [GAD-7]) and improvements in quality of life (WHOQOL-BREF [World Health Organization Quality of Life–BREF]). No statistically significant changes were observed

XSL•FO
RenderX

in Perceived Stress Scale (PSS) scores, suggesting that while the VR program effectively enhanced emotional well-being, it may not directly influence stress-related factors. The intervention appeared particularly beneficial for participants at higher baseline risk for depression and anxiety. Similarly, Caballero-Galilea et al [40] found that controlled VR exposure to the childbirth process reduced pregnancy-related anxiety in third-trimester women. Noben et al [45] evaluated the use of 360° VR videos to prepare women and their partners for elective cesarean delivery. Although the intervention did not significantly reduce overall preoperative anxiety compared with standard information provision, most participants, both women and partners, reported feeling more prepared and less fearful about the upcoming procedure. Qualitative feedback indicated that the immersive visualization of the operating room and surgical process fostered familiarity and reduced uncertainty, particularly among those with prior emergency cesarean experience. Thus, while VR did not achieve a statistically significant decrease in anxiety scores, it enhanced perceived preparedness and satisfaction, suggesting potential benefits in specific subgroups. Xie et al [23] showed that women receiving VR-based prenatal education combined with perineal protection reported significantly lower anxiety. FOC was a specific target in 2 studies [41,42], both of which reported reductions in FOC levels and positive user feedback on emotional preparedness after participation in VR-based childbirth education. Park and Kim [47] conducted an experimental study targeting pregnant women hospitalized for preterm labor. The intervention group who received VR-based prenatal education demonstrated statistically significant improvements in self-efficacy, pregnancy-related knowledge, and emotional stability, along with a higher perceived usefulness of the training content compared to the control group. The VR program provided tailored content that addressed psychological well-being during hospitalization and included simulations of childbirth and newborn care. Importantly, participants in the VR group showed lower levels of anxiety and stress and greater readiness for labor and postpartum care.

To summarize, 9 out of 11 (81.8%) studies [23,34,40-48] assessed psychological or emotional dimensions such as anxiety, depression, perceived stress, or FOC. Among these, 7 [23,24,40-42,45,47] out of 11 studies [23,34,40-48] (63.6%) reported statistically significant or qualitatively positive effects on anxiety or related constructs. Specifically, studies [23,34,40,45] reported measurable anxiety reduction following exposure to immersive prenatal or perinatal experiences. Siivola et al [41,42] observed reductions in FOC and enhanced emotional readiness, while Park et al [47] found decreased stress and improved emotional stability in hospitalized women receiving VR-based prenatal education. One study [46] focused primarily on physical activity and did not measure mental health outcomes, whereas another [44] reported mixed results, some participants described VR breastfeeding simulations as “emotionally demanding” or “challenging,” suggesting that immersive realism can occasionally elicit discomfort alongside learning benefits. Overall, these findings suggest that immersive XR interventions could have an impact on enhancing psychological well-being, though emotional responses are related to the realism and sensitivity of the simulated content.

Physiological Outcomes

Some studies incorporated physiological or behavioral measures to complement psychological outcomes. VR-assisted prenatal preparation was associated with lower maternal heart rate, reduced pain scores, and higher rates of perineal integrity during childbirth [23]. Setiawan et al [46] monitored vital parameters before and after each VR-based exercise session, observing no adverse cardiovascular responses and confirming the feasibility of moderate physical activity guided through immersive environments. Similarly, Park et al [47] reported that VR relaxation modules stabilized uterine activity among women hospitalized with threatened preterm labor, contributing to improved comfort and adherence to treatment. Across all studies, no serious adverse effects were observed; minor discomfort, such as transient dizziness or eye fatigue, was infrequently reported and self-resolving. To summarize, 3 (30%) studies [23,46,47] reported physiological or obstetric indicators, either as primary or secondary outcomes. Among them, Xie et al [23] documented significant improvements in childbirth-related parameters, including reduced pain scores, higher rates of intact perineum, and shorter labor duration in the VR-assisted group. Park et al [47] observed stabilization of physiological stress markers such as systolic blood pressure, heart rate, and uterine activity. Setiawan et al [46] confirmed the safety and feasibility of VR-guided exercise, with no adverse cardiovascular responses. No study reported serious side effects, and among the few studies that assessed VR-related tolerability, adverse effects were generally absent or limited to minor, transient complaints. Noben et al [45] reported no discomfort or motion sickness, Setiawan et al [46] found no postsession nausea, vomiting, or dizziness, and Siivola et al [41] reported no motion sickness during testing. Minor transient adverse events were documented in only 2 studies (<20%): Siivola et al [42], in which 1 participant reported eye strain and another minor HMD-related discomfort, and Park et al [47], which reported 1 withdrawal due to HMD-related discomfort. Overall, most studies did not systematically assess VR-related side effects.

Educational Outcomes

Educational impact was evaluated through measures of knowledge acquisition, engagement, motivation, and self-efficacy. Siivola et al [41,42] developed and tested immersive childbirth education programs using 360° videos and VR headsets. Participants consistently rated the experiences as usable, realistic, and engaging, with reported improvements in childbirth knowledge and preparedness. However, evidence regarding the FOC reduction remains inconclusive. Tang et al [43,44] found that VR breastfeeding simulations supported experiential learning through embodied interactions, enabling users to visualize and practice realistic feeding challenges in a safe context. However, a subset of users reported frustration with the lack of explicit feedback or structured guidance during the simulation. Montoya-Moncada et al [48] found no statistically significant differences between the MR-based educational strategy and traditional breastfeeding counseling in terms of maternal self-efficacy and satisfaction. Park et al [47] highlighted that immersive prenatal modules improved engagement, comprehension, and emotional connection to content, aligning with the principles of the IMCHB model.

XSL•FO
RenderX

Setiawan et al [46] demonstrated that VR exercise programs for pregnant women are feasible and could positively impact adherence to physical activity, suggesting behavioral reinforcement potential through gamified, self-paced environments. Overall, 6 [41-44,46,47] out of 11 studies [23,34,40-48] (54.5%) explicitly evaluated educational end points, such as knowledge acquisition, preparedness for childbirth, self-efficacy, or skill transfer. The studies [41-44,47] reported improvements in knowledge retention, confidence, and comprehension, particularly when interactive or 360° scenarios were used. Setiawan et al [46] found increased motivation and adherence to prenatal exercise programs, suggesting educational reinforcement through gamified feedback. Conversely, Caballero-Galilea et al [40] observed reductions in anxiety but did not detect significant changes in perceived knowledge, and one breastfeeding simulation study [44] noted that while participants valued the realism, they sought clearer instructional guidance. Approximately two-thirds of the included studies demonstrated enhanced learning or self-efficacy outcomes, though some highlighted the need for improved instructional design within immersive systems.

Experiential Outcomes

User-centered evaluations were prominent in at least 6 (60%) studies [41,42,44-47], which mainly investigated usability, comfort, and motion sickness. Most users reported high satisfaction and found the VR interfaces intuitive, with minor reports of motion discomfort. Studies reported user-centered or experiential metrics, including usability, acceptability, immersion, and motion sickness. Across these, most participants described immersive experiences as engaging, realistic, and emotionally meaningful. Some studies [41-44] emphasized the positive influence of interactivity and presence on emotional engagement. Other [44] noted occasional discomfort or cognitive overload among participants unfamiliar with VR interfaces. Reports of motion sickness were infrequent and mild.

Overall, user experience outcomes were favorable in the included studies, supporting the feasibility and acceptability of immersive prenatal and perinatal education.

When aggregated, 9 [23,34,40-42,45-48] of 11 studies [23,34,40-48] (81.8%) reported at least 1 positive outcome domain, and 6 [23,34,41,43,46,48] of 11 [23,34,40-48] (54.5%) demonstrated statistically significant improvements in at least one primary variable (eg, anxiety, pain, knowledge, or satisfaction). Psychological and educational benefits were the most consistent, particularly in anxiety reduction and learning engagement, although results were heterogeneous for FOC and preoperative anxiety. Physiological and experiential outcomes showed promising but preliminary evidence of safety and acceptability. Taken together, these findings reinforce the potential of XR technologies, especially VR, to enhance emotional readiness, experiential learning, and patient engagement during pregnancy and childbirth, while highlighting the need for larger, standardized, and multicenter studies to validate these early results. Tables 2-6 present a comprehensive overview of the included studies, summarizing study characteristics, participant demographics, methodological features, key results and implications, and details of the educational programs, including technological components and content design.

RQ3: What Challenges and Limitations Are Identified in the Integration of XR Into Prenatal Courses?

RQ3 examined the methodological diversity and implementation challenges reported in the included studies. As summarized in Table 3, methodological heterogeneity was observed across the included studies, reflecting the exploratory nature of research on immersive and XR technologies in prenatal and childbirth education. While some studies [23,34,40,45,47] adopted controlled or quasi-experimental frameworks to assess measurable outcomes, such as anxiety reduction or physiological responses, others relied on exploratory or design-based methodologies to examine user perceptions, usability, or content development processes. This diversity illustrates the coexistence of intervention trials and formative research, each contributing different types of evidence to the field. Differences also emerged in the exposure design and delivery parameters. The duration and frequency of immersive experiences varied considerably, from single brief sessions focusing on emotional regulation or preoperative preparation to multiweek interventions structured as comprehensive educational programs. The level of immersion also ranged widely, encompassing fully immersive VR headsets, semi-immersive 360° video environments, and hybrid configurations integrating soundscapes, narration, or limited interactivity. The measurement tools and outcome frameworks were equally inconsistent. Psychological outcomes such as anxiety, depression, or FOC were assessed with different validated instruments [eg, the State-Trait Anxiety Inventory (STAI), the Wijma Delivery Expectancy/Experience Questionnaire (W-DEQ), and the Edinburgh Postnatal Depression Scale (EPDS)], which hinders cross-study comparison. In contrast, educational and experiential outcomes were often measured through ad hoc questionnaires or qualitative interviews, limiting external validity but providing valuable insight into user engagement and emotional resonance. Some quantitative studies applied inferential statistics to compare intervention and control groups, whereas qualitative research emphasized thematic synthesis or user-centered evaluation frameworks. Follow-up assessments were infrequently conducted, reducing the capacity to assess long-term retention or behavioral impact. Most studies recruited only women, with sample sizes ranging from 10 participants in qualitative co-design studies [44] to 200 participants in randomized clinical trials [23]. Eligibility criteria were often highly restrictive, for example, targeting primiparous women without complications [23] or patients scheduled for elective cesarean delivery [45]. Such selectivity, while enhancing internal validity, reduces generalizability and further contributes to the methodological heterogeneity observed across the field. Intervention structures also differed markedly. For instance, Lee et al [34] implemented a progressive multimodule VR mental health program, Setiawan et al [46] integrated pre- and postsession physiological monitoring during VR exercise, and Park et al [47] developed a guided prenatal education model using the IMCHB framework for hospitalized women. This diversity of methodological orientations, ranging from structured trials to exploratory pilot studies, reflects both the experimental

XSL•FO
RenderX

stage and the rapid evolution of immersive applications in prenatal education. Despite increasing recognition of coparenting and partner involvement, only 3 studies [43-45] explicitly included partners. This underscores an underexplored area for future research on shared learning and emotional coregulation during the perinatal period. Equity and accessibility were addressed in a limited number of studies. Barriers such as digital literacy, comfort, device availability, and motion sensitivity were acknowledged as potential obstacles to the equitable adoption of immersive education. Notably, the inclusion of multidevice access options (eg, VR headset, tablet, or smartphone [41,42,47]) was viewed positively by users, emphasizing the importance of flexible and inclusive design approaches for diverse populations. Overall, the methodological heterogeneity across studies underscores both the innovation potential and the fragmentation of current immersive technologies research in prenatal care. The field would benefit from shared methodological guidelines, standardized reporting criteria, and mixed methods designs that integrate psychological, educational, and experiential dimensions within unified evaluation frameworks.

RQ4: What Methodologies and Technological Approaches Are Commonly Used in Studies on XR for Prenatal Education?

RQ4 analyzed the technological and design characteristics of XR interventions, including hardware, software, and the structure of the immersive content. Technological diversity was substantial across studies, reflecting the evolving and experimental nature of immersive technological applications in maternal health. Most interventions used HMDs such as Oculus Rift, Oculus Quest, or smartphone-compatible VR viewers [34,41-44,46,47], allowing full or semi-immersive 3D visualization of childbirth or breastfeeding scenarios. Others implemented 360° panoramic videos accessible via computers, tablets, or mobile devices to broaden accessibility and minimize cybersickness [41,42,45].

Software environments were typically developed using Unity (Unity Technologies) or Pano2VR (Garden Gnome Software), integrated with supplementary editing tools such as Adobe Premiere Pro (Adobe Inc) and HandBrake (HandBrake Team) for video compression and cross-platform usability [41-43].

Across studies, immersive content was structured around thematic educational modules:

- Childbirth process simulations, including stages of labor, pain management, and hospital familiarization [23,41,42].
- Mental health and relaxation modules, focusing on stress reduction, guided breathing, and emotional resilience [34,47].
- Skill-based training, such as breastfeeding interaction scenarios and prenatal physical exercise routines [43,44,46,48].

Most interventions combined visual, auditory, and interactive cues to enhance engagement and learning transfer. Some included embodied tasks, for example, hand motion tracking, tactile interaction with a doll and/or silicone breast model [43,44,48], or guided voice-over narration simulating clinician or midwife presence [47]. User experience design was generally informed by user-centered frameworks and pedagogical models such as the IMCHB model and constructivist learning theory, emphasizing experiential learning through realistic simulation [47].

Overall, immersive technologies demonstrated versatility in integrating multisensory and interactive components adaptable to both clinical and home environments. However, variation in technical specifications and delivery platforms underscores the current lack of standardization in immersive maternal education tools.

RQ5: What Research Gaps Exist in This Area, and What Future Directions Are Recommended?

First, modest sample sizes and narrow eligibility criteria (eg, low-risk, primiparous women or inpatient cohorts) limit generalizability and constrain inferences about the applicability of XR. Only 3 studies enrolled partners [43-45], despite growing evidence in favor of shared parental education. Second, heterogeneity in study designs and measurement approaches hampers cross-study comparisons and meta-analytic synthesis. Psychological outcomes were often captured with validated scales, whereas experiential and usability outcomes frequently relied on ad hoc instruments. Standardized, validated tools tailored to XR-based maternal education remain lacking. Technologically, few interventions collected objective usability metrics (eg, engagement time and motion-tracking data), and accessibility testing for participants with low digital literacy or limited device access was rarely undertaken [41,42]. Moreover, ethical and equity considerations, including data privacy, the digital divide, and cultural adaptation of immersive content, were seldom discussed, despite their importance for global health implementation. Additional work should examine the suitability of mixed-reality tools across diverse populations, particularly in low- and middle-income countries where access to innovative educational strategies may be constrained yet potentially highly beneficial [48]. Future research should deploy RCTs that use more intensive educational strategies, incorporate multiple sessions, and extend follow-up to clarify long-term effects on maternal self-efficacy, satisfaction, and exclusive breastfeeding rates [48]. Finally, there remains a pressing need for longitudinal and comparative studies that evaluate behavioral and clinical outcomes beyond the immediate postpartum period. Researchers should explore scalable, low-cost immersive solutions and hybrid learning models that combine simulation with interpersonal support. Collaborative, interdisciplinary efforts, linking clinicians, designers, and educators, are essential to establish best practices and ensure safe, inclusive integration of XR technologies into prenatal and childbirth education.

Overall Summary of Findings

Overall, the synthesis across RQ1-RQ5 indicates that immersive and XR technologies are being increasingly integrated into prenatal and childbirth education with encouraging outcomes across psychological, physiological, educational, and experiential domains. Despite methodological heterogeneity and small sample sizes, most studies demonstrated positive effects on anxiety reduction, learning engagement, and emotional preparedness. However, limited standardization in

XSL•FO
RenderX

design, measurement, and accessibility testing highlights the early developmental stage of this field. These results collectively support the feasibility and potential of XR as an innovative complement to conventional prenatal education, while underscoring the need for rigorous, inclusive, and longitudinal research to consolidate its evidence base.

Thematic Analysis

A total of 5 major themes and the related subthemes emerged from the analysis. To further contextualize these patterns, we have integrated responses to the 5 guiding research questions underpinning this review, supported by evidence from the included academic literature. Proportions refer to the 11 included studies [23,34,40-48].

Theme 1: VR as a Catalyst for Emotional, Cognitive, Physical, and Physiological Outcomes

This theme explores how immersive experiences promote emotional readiness, self-efficacy, and physiological comfort during pregnancy and childbirth. Across 8 [23,34,40,42,45-48] of 11 [23,34,40-48] (72.7%) studies, immersive or semi-immersive VR interventions demonstrated a measurable positive impact on participants' emotional regulation, childbirth-related self-efficacy, and perceived control during pregnancy and labor. Several studies explicitly reported reductions in anxiety, depressive symptoms, or FOC, particularly when VR was used to visualize the childbirth process or to simulate relaxation exercises [34-38,40-43,48-51]. Physiological parameters also improved in studies integrating biobehavioral monitoring: VR-based prenatal education combined with perineal protection lowered pain scores and postpartum bleeding [23]; VR-guided relaxation stabilized uterine activity in women with preterm labor [47]; and VR-assisted exercise programs showed no adverse cardiovascular effects [46]. Not all outcomes moved in the same direction: an RCT of a VR operating room walkthrough before an elective cesarean did not significantly reduce preoperative anxiety overall, although participants (and partners) reported feeling better prepared and no motion sickness was observed [45]. Overall, 9 [23,34,40-42,45-48] out of 11 [23,34,40-48] (81.8%) studies reported at least 1 beneficial psychological or physiological outcome, while 4 [23,34,40,47] of 11 (36.4%) [23,34,40-48] showed statistically significant improvement in at least 1 quantitative measure. These findings suggest that immersive experiences can promote emotional stability, physiological adaptation, and empowerment during pregnancy and childbirth.

- Enhanced self-efficacy, confidence, and perceived control among women during childbirth (9/11, 81.2%): immersive learning strengthened mothers' confidence and perceived control during childbirth [23,34,40-42,45-47].
- Distraction and emotional relief before and during childbirth (3/11, 27.3%): VR provided psychological distraction and emotional relief, reducing anxiety and stress through calming, immersive environments [34,40,45].
- Impact on physical or physiological parameters (3/11, 27.3%): immersive exposure was associated with reductions in pain and no adverse cardiovascular effects [23,46,47].

Theme 2: Customization, Sense of Presence, and Realism as Engagement Drivers

This theme captures how realism, presence, and adaptive learning features influence user engagement and satisfaction. Engagement was strongly shaped by audiovisual fidelity, a convincing sense of presence, and the possibility to tailor content. Users frequently described "being there" (eg, inside the birthing room) as key to relevance and motivation, and they valued options to progress independently [41,42]. At the same time, design tensions emerged when simulations looked or felt "game-like," creating unmet expectations for guidance, interactivity, or rewards; these microfrictions could chip away at immersion if not intentionally balanced [43,44].

Based on the contents, the following 3 subthemes emerged:

- Realism, immersion, and sense of presence (4/11, 36.4%): authentic audiovisual fidelity fostered emotional connection and meaningful engagement (eg, 360° hospital tours and realistic birthing scenarios) [41-44].
- Customization and personalization (2/11, 18.2%): users valued flexibility and the ability to tailor learning pace and content to personal needs [43,44].
- Participant satisfaction (4/11, 36.4%): overall satisfaction with VR experiences was high compared with traditional courses [40,42,46,47].

Theme 3: Technical and Usability Considerations

This theme synthesizes participants' feedback on the accessibility, usability, and technical limitations of immersive systems. Most users found VR interventions engaging, although minor barriers related to device comfort, navigation, or unfamiliarity with the technology were reported [44,46]. Feasibility and acceptability were generally good, with some device-related or interface hurdles. Multidevice access (HMD, computer, tablet, and smartphone) improved reach and scheduling flexibility, and HMDs often offered the best usability and presence [41,42].

The following subthemes are highlighted:

- Device flexibility and accessibility (5/11, 45.5%): VR allowed participation independent of place or schedule [34,40-42,44].
- Usability (ease of learning; 2/11, 18.2%): overall good usability, particularly with the headsets [41,42].
- Safety and tolerability: no serious adverse events reported (5/11, 45.5%) [23,34,40-42].
- Technological barriers (5/11, 45.5%): users occasionally experienced discomfort or interface issues [40-44].

Theme 4: VR as an Educational and Motivational Tool

This theme relates to cognitive learning, behavioral readiness, and social engagement facilitated by immersive tools. Most studies reported gains in knowledge, preparedness, and motivation. VR hospital tours about childbirth modules improved learning outcomes and provided concrete, realistic exemplars; VR-based programs also strengthened self-management and pregnancy care behaviors in higher-risk settings (eg, [42,47]). Immersive scenarios around breastfeeding surfaced lived challenges and promoted reflection and dialogue,

XSL•FO
RenderX

complementing traditional didactics by addressing expectations and social or contextual barriers rarely covered in standard courses [43,44]. Preoperative VR for cesarean enhanced perceived preparedness in most women and their partners, highlighting motivational and informational value even when affective endpoints do not shift [45].

- Knowledge acquisition and retention (8/11, 72.7%): participants demonstrated improved understanding and recall of prenatal concepts [23,40-44,46,47].
- Ability to identify signs or symptoms of childbirth (5/11, 45.5%): VR improved recognition of early labor indicators and features related to breastfeeding experience [41,43,44,46,47].
- Coresponsibility and partner involvement (3/11, 27.3%): immersive education encouraged shared learning between partners [43-45].
- Recommendation to future parents (2/11, 18.2%): participants widely endorsed VR courses for peers [42,46].

Theme 5: Limitations

This final theme reflects methodological constraints and research priorities. Methodological constraints and implementation gaps temper generalizability. Several studies used small samples, single-group designs, or short follow-ups, and psychological outcomes were measured with heterogeneous tools. Selection biases and context-specific prototypes (eg, single-site pilots) were common, and partner or diverse-population representation was limited [40-43]. The main limits identified are the following:

1. Improving sample size (7/11, 63.6%) [34,40-42,45-47].
2. Lack of control group (3/11, 27.3%) [34,40,47].
3. Missing information (4/11, 36.4%): some studies pointed out the limited standardization especially about the measures used to assess psychological variables [23,40,42,45].
4. Selection biases (4/11, 36.4%) [34,41,45,46]: several studies point to the difficulty of accessing large and diverse samples, often having to resort to convenience sampling.
5. Confounding effect related to added intervention (VR and perineal protection [23]).
6. Inclusivity and contextual adaptation (4/11, 36.4%) [42-44,50].
7. Learning curve and technical literacy (4/11, 36.4%): limited familiarity with VR required orientation or staff support [42,43,46,47].
8. Lack of contextual and interactive cues and balanced gamification [42].
9. Lack of customization [34,44].
10. Lack of haptic feedback: the lack of perception of any type of pressure or vibration by participants may reduce their engagement with this technology [44].

Synthesis of Thematic Findings

Overall, from the thematic analysis, it emerges that immersive interventions primarily enhance emotional regulation, self-efficacy, and knowledge retention, reported in 70% - 80% of the included studies. Engagement is strongly linked to realism, presence, and personalization, while usability and equity remain key implementation challenges (eg, [23,34,40,47]).

Despite small samples and methodological variability, the findings collectively portray VR as a promising, user-accepted innovation for prenatal and childbirth education. The 5 themes identified were closely interrelated rather than independent. Realism and sense of presence appeared to be a central mechanism linking the technological features of immersive scenarios with users' psychological and educational outcomes. High levels of realism and immersion fostered emotional engagement and a stronger sense of preparedness, directly reinforcing confidence and learning outcomes. However, when the simulated experience became overly realistic or emotionally intense, participants occasionally reported discomfort, thereby connecting this theme to usability and instructional barriers. The need for structured guidance and emotional containment emerged as a mediating factor that shaped whether realism translated into positive or overwhelming experiences [41,44]. Similarly, the educational and motivational value of interventions was strongly influenced by the balance between realism and usability: participants were most motivated and confident when the immersive environment was both intuitive and emotionally manageable [42,43,47]. Finally, methodological and inclusivity limitations, such as small samples, short-term follow-up, and the underrepresentation of partners, acted as contextual moderators that constrained the generalizability of these interrelations [40,44,45]. Taken together, these interconnections suggest that the effectiveness of immersive scenarios in prenatal and childbirth education could be related to achieving equilibrium between immersion, usability, and emotional safety, ensuring that technological engagement consistently translates into meaningful learning and psychological benefit.

Discussion

Summary of Evidence

This scoping review underscores the growing importance of XR technologies in prenatal education, highlighting their diverse applications and potential benefits for expectant parents. Across heterogeneous designs and targets, XR (predominantly head-mounted VR and 360° video) emerged as a context-enabling technology that shapes expectations, self-efficacy, and preparedness.

The most consistently discussed mechanisms, warranting further investigation, were (1) presence and realism that situate users in concrete care pathways or lived scenarios (eg, birthing rooms and breastfeeding in public), aligning expectations with reality; (2) scaffolding (briefing, in-experience cues, and debriefing) to convert immersion into learning rather than overload; and (3) personalization and customization of pace, content, and intensity to match emotional readiness. These points recur in evaluations of childbirth education modules and breastfeeding simulations, which emphasize that simulations work best when they surface real-world complexity while remaining emotionally manageable [41-44]. Several included studies did not offer comprehensive VR-based childbirth training. Some interventions primarily targeted mental health promotion or general antenatal information, with childbirth skills training still provided via standard modalities; as a result, the evidence base appears

XSL•FO
RenderX

stronger for preparedness and emotional regulation than for hands-on childbirth skills acquisition [34,40].

Not all affective end points shift uniformly. In the precesarean study using a 360° operating room walkthrough, overall preoperative anxiety did not significantly decline; however, participants felt better prepared and motion sickness was negligible, suggesting that VR may be more valuable for expectation setting and preparedness in this context [45]. By contrast, programs targeting mental health promotion during pregnancy reported reductions in depressive and anxiety symptoms and gains in quality of life, with stronger effects in higher-severity subgroups, consistent with VR acting as a precision amplifier when distress is greater [34,40]. This pattern aligns with broader VR evidence showing clinically meaningful anxiolytic and analgesic effects across nonobstetric contexts and robust efficacy for anxiety disorders in randomized trials [53-55].

In a recent noninferiority randomized trial evaluating an MR adjunct to standard prenatal counseling, there were no between-group differences in maternal self-efficacy or satisfaction at 1 week postpartum; however, exclusive breastfeeding reached 93.1% in both arms, indicating high baseline supports and potential ceiling effects [48].

Where VR was embedded alongside biobehavioral cointerventions (eg, perineal-protection techniques taught within a VR-supported prenatal program), studies discussed pragmatic benefits (eg, lower pain) while cautioning that future trials must disentangle the VR effect from the added clinical component [23]. From a design perspective, breastfeeding simulations repeatedly highlight a productive tension: when experiences feel game-like, users expect goals, feedback, and progression; if those are absent, microfrictions can erode engagement. Authors, therefore, advocate measured gamification (clear objectives and contextual feedback) and structured debriefs that channel emotional impact into reflection and action, principles that generalize to other perinatal VR modules [43,44]. Finally, implementation work converges on a practical message: HMDs maximize presence and usability for key sessions, but multidevice access (HMD plus PC or tablet or phone) broadens reach and equity for rehearsal and partner involvement. Brief sessions, seated posture, orientation, and clinician facilitation improve tolerance and learning transfer [41-44,47].

Findings converge with nonobstetric meta-analyses reporting consistent VR-driven reductions in pain and anxiety, and with clinical education studies where brief, expectation-aligned VR modules improve understanding when embedded in routine workflows [53-56]. In obstetrics, pooled analyses suggest state anxiety reductions during routine procedures without consistent maternal-fetal safety signals, albeit with reporting heterogeneity and short follow-up [24,57,58]. Overall, our results extend this literature by focusing on parent-facing prenatal education, emphasizing emotional preparedness, usability across digital literacy levels, and the value of facilitated debriefing, which are less central in clinician training research.

Implications for Clinical Practice

The findings of this scoping review suggest several concrete ways in which XR can be incorporated into prenatal care pathways. For parents scheduled for elective cesarean delivery, VR appears particularly useful as an informational and pathway-familiarization tool. Short, guided 360° tours of the operating theater and perioperative environment can strengthen perceived preparedness, even when mean anxiety scores do not change, and may be especially valuable for those with a history of emergency cesarean or heightened fear of surgery. Wherever possible, partners should be included so that both members of the dyad share a realistic understanding of the procedure and the perioperative setting [45].

Immersive programs that primarily target antenatal mental health, combining positive affect induction, psychoeducation, and relaxation or mindfulness elements, have shown reductions in depressive and anxiety symptoms and improvements in quality of life, with larger effects among higher-severity subgroups [34,41,42,46,47]. Clinically, this pattern supports the use of VR as an adjunctive component within stepped care models rather than as a stand-alone treatment. Brief, structured sessions can be embedded in routine antenatal visits to support emotional regulation, while more intensive psychotherapeutic strategies are likely to remain necessary when the aim is to modify stress appraisal and coping, which changed less consistently in the included trials [34,41,42,46,47]. Converging evidence from nonobstetric meta-analyses supports VR's adjunct role in reducing state anxiety in routine care pathways [53-55].

Within childbirth education and early parenting programs, headset-based, scenario-driven modules can be reserved for key sessions that introduce labor environments, decision points, and immediate postnatal routines, whereas remote 360° or video content can serve as refreshers to consolidate learning and allow parents to revisit material together at home [43-45].

For breastfeeding preparation, lived experience simulations that depict common technical and social challenges, such as latching difficulties or feeding in public, can help parents anticipate and normalize difficulties. Their impact appears greatest when VR sessions are framed and debriefed by midwives or lactation consultants, turning emotionally salient experiences into concrete action plans. Evidence from neonatal intensive care settings further suggests that VR may support lactation among mothers of preterm infants by reducing anxiety and enhancing expressed milk volume, although effects on self-efficacy and satisfaction depend on the quality of underlying counseling [43,44,48,59].

Across all applications, implementation choices shape both effectiveness and safety. The studies included in this review indicate that keeping sessions brief (around 10 - 15 min), using a seated posture, and allowing user-controlled pacing minimizes cybersickness and fatigue; no serious adverse events were reported, and obstetric meta-analyses likewise describe stable maternal and fetal parameters during short, guided uses [45,60].

When experiences adopt game-like conventions, it is important to make learning goals explicit and to provide light-touch feedback (eg, progress cues or hints), so that playfulness sustains

XSL•FO
RenderX

engagement without trivializing care content [43,44]. Coviewing and partner involvement generally improve dyadic preparedness and adherence [45], and hybrid delivery models, combining clinic-based HMDs for high-presence moments with multidevice access (HMD, tablet, or smartphone) for rehearsal at home, may offer a pragmatic balance between fidelity, reach, and equity in diverse populations [41-44,47,61-64].

Implications for Future Research

Future research on XR-based prenatal education would benefit from greater methodological convergence. Across the included studies, outcome measures for anxiety, FOC, self-efficacy, and preparedness were highly fragmented, and reporting of presence, realism, and debriefing formats was inconsistent. Developing core outcome sets and agreed-upon reporting standards for VR "dose" (eg, frequency, duration, and hardware characteristics) and facilitation strategies would enhance comparability and support robust meta-analysis. Safety reporting should routinely include maternal hemodynamics, fetal heart rate patterns, and neonatal indicators, in line with emerging obstetric meta-analyses on intrapartum VR [24,40-44,47,50,57].

Several trials suggest that immersive programs may be particularly helpful for individuals with higher baseline distress, such as those with elevated depression or anxiety scores, or pronounced childbirth fear [34,41,42,46,47]. This pattern points to the need for studies that are prospectively powered for subgroup analyses, include prespecified interaction tests, and, where feasible, use adaptive designs to identify who benefits most and at what time point in pregnancy. In addition, family-centered outcomes, such as partner preparedness, dyadic coping, and coparenting adjustment, remain undermeasured despite growing evidence on paternal mental health and engagement. Future trials should therefore integrate these end points and draw on paternal-engagement frameworks when designing XR content [61-64].

Many of the interventions identified in the current review combined VR with additional components, including perineal protection techniques, structured counseling, or hands-on practice with task trainers, which makes it difficult to isolate the specific contribution of immersion. Future work should use active comparators or factorial designs to disentangle VR effects from cointerventions and to quantify how presence, guidance, and repetition relate to psychological and clinical outcomes [23]. Insights from rehabilitation science, where VR has been used extensively to structure motor learning schedules, could help specify dose-response relationships and practice parameters for perinatal education [65]. In parallel, design lessons emerging from breastfeeding simulations and co-design prototypes, such as embracing uncertainty while offering context-relevant feedback and enabling customization of family composition and environments, should be translated into testable design requirements and evaluated prospectively, even when initial prototypes fall outside strict effectiveness trial criteria [43,44]. Finally, implementation-focused and real-world research is needed to understand how immersive prenatal education can be scaled and sustained. Multicenter pragmatic trials should track uptake, completion rates, costs, and equity impacts, including representation of underserved groups and partner participation [41-44,47]. Given that early studies often restricted the use of headsets to clinic settings and resorted to nonimmersive devices for remote delivery, future work should evaluate models that provide loaner HMDs and home-based protocols with remote safety monitoring, comparing them with non-HMD approaches in terms of adherence, safety, user experience, and outcomes. Such implementation studies can inform guidelines for integrating XR into hybrid antenatal care pathways while safeguarding accessibility, inclusivity, and safety.

Limitations

Although our search spanned XR broadly, included studies were almost exclusively VR or 360°, with 1 MR trial, underscoring a modality gap [48]. Small samples, single-site prototypes, short follow-up, and heterogeneous measures limit generalizability and synthesis; some HCI-led prototypes caution that game-like framing can create normative expectations unless customization is provided [34-38,40-47,49-51]. Acceptability and safety were high overall, yet digital literacy and brief orientation remain prerequisites; where VR is embedded in multicomponent care, physiologic and clinical end points appear promising but attribution to VR alone is uncertain [23]. In obstetrics, evidence suggests anxiety reductions without consistent safety concerns, but reporting remains variable [24,57,58]. Finally, RCT work in breastfeeding points to targeted experiential benefits warranting replication and linkage to clinical end points [66].

Conclusions

For perinatal care, VR is most effective when high presence is matched with structured guidance and personalization, turning immersive exposure into meaningful preparedness and emotional regulation. Clinically, this translates into targeted use (eg, elective cesarean preparation and higher-severity mental health profiles) and hybrid delivery that balances fidelity with reach. For the field to mature, we need standardized outcomes, subgroup-powered pragmatic trials, and designs that separate VR's contribution from cointerventions while operationalizing HCI insights (uncertainty, feedback, and customization) as testable requirements. Integrating insights from broader VR meta-analyses and adjacent pediatric and rehabilitation domains strengthens the rationale for perinatal VR, while pointing to concrete design and implementation levers, partner inclusion, at-home HMD access, and safety-standardized reporting, that can accelerate translation into routine care.

Abstract

Background: Technology is integrated into many children's daily lives, with parents' and health professionals' perspectives shaping children's technology use. Measuring and understanding these perspectives are essential for developing strategies for supporting adults in decision-making that help children thrive in a digital world.

Objective: This systematic review aimed to investigate the psychometric properties of questionnaires used to assess parents' and health professionals' perspectives on young children's use of technology related to health, well-being, and development. The secondary aim was to synthesize findings on these perspectives.

Methods: Peer-reviewed papers published between January 2010 and September 2024 were identified through searches in 7 electronic databases. Studies were included if they examined parental or health care professionals' perspectives on technology use among children aged birth to 5 years. Two reviewers (CLR and IPHA) independently conducted the data extraction and study quality assessment. Reported psychometric properties of the questionnaires were synthesized. Deductive thematic analysis was used to explore the content focus of the questionnaire used in the included studies and synthesize the reported perspectives.

Results: In total, 85 studies were included, all involving parents. No study investigated health professionals' perspectives. The methodological quality of the studies was generally low, with 62 studies scoring below the threshold for acceptable quality. In total, 52 studies reported psychometric properties of the questionnaires used, of which, only 15 studies reported more than 1 measure of validity or reliability. A total of 75 studies reported participants' perspectives on children's technology use. Findings revealed that parents generally supported the role of digital devices in enhancing learning but expressed concerns about potential negative impacts on children's physical health, emotions, and behaviors.

Conclusions: Parents' perspectives on children's technology use were frequently assessed through questionnaires, though the validity of these questionnaires was often poor, with limited psychometric testing. Parental perspectives were mixed with educational benefits being recognized, while countered with concerns about the impact on children's physical health and development. High-quality questionnaires are needed to generate stronger evidence informing strategies to support families in technology use decision-making with and for children.

Introduction

Technology is now an integrated part of many children's daily lives [1-3], encompassing both screen-based (eg, tablets, smartphones, and computers) and nonscreen-based (eg, smart toys and interactive learning tools) devices [4]. Recent survey data indicate a substantial increase in young children's technology use. For example, data from the United States suggest that children younger than 8 years of age spend ~2.5 hours per day on screen devices [3], while Australian children aged 2 - 6 years are estimated to spend ~25.9 hours per week [1]. The rise in young children's technology use has led to an increase in research, assessing its potential benefits and harms for children's health, well-being, and development [5]. Evidence suggests that technologies can enhance learning, language development, creativity, and support social connections [6-9]. However, excessive screen time has been associated with negative health effects, including sleep disturbances and obesity [10,11]. Moreover, exposure to inappropriate content has been linked to emotional and behavioral challenges such as attention issues and anxiety [7]. These mixed results highlight the complexity of technology's role in the health, well-being, and development of young children (birth to 5 years), and how factors such as content, context, and duration of use can influence technology's role [12].

Children's interaction with technology happens within a system, whereby multiple factors influence how children use technology [13,14]. One of these factors is the perspectives (ie, beliefs, attitudes, and viewpoints) of key adult figures in children's lives, including parents, educators, and health professionals. Parents are often primary mediators of children's technology use, as they play a central role in shaping technology use by setting rules, providing supervision, and coengagement. Thus, parent perspectives may influence children's use of technology and its impact on their health, well-being, and development [15,16]. Research suggests that parents hold mixed perspectives on children's technology use, mirroring broader public debates [17]. In total, 3 systematic reviews found that parents hold concerns about the negative impacts of screen time on children's physical health, social skills, exposure to inappropriate content, and development of addiction [18-20]. In contrast, the review by Choy et al [19] also found that parents perceived technology to be beneficial for learning, creativity, digital literacy, and social-emotional development. While these findings provide some insights into the complexity of parents' perspectives toward technology, the reviews by Chong et al [18] and Visier-Alfonso et al [20] only considered qualitative studies [18,20]. Moreover, Chong et al [18] did not investigate positive views on screen time, and the reviews by Visier-Alfonso et al [20] and Choy et al [19] only included studies that reported on technologies used to support physical activities or were internet-based.

Health professionals, such as medical doctors, child health nurses, and allied health professionals, are a trusted information source [16] who provide recommendations on healthy technology use, which parents often rely upon to make informed decisions about their children's digital engagement. However, their perspectives on children's technology use have not been systematically investigated and synthesized. Educators play a crucial role in enhancing learning experiences and digital literacy within the early learning and school environment and in supporting parents [15]. The perspectives of educators on children's technology use have been extensively discussed [15,21,22] and appear to reflect the broader community and parent perspectives. Specifically, educators have been found to hold positive views on the use of technology to support learning and engagement while also expressing concerns about exposure to inappropriate content and overuse. Given the substantial body of research on this topic, educators' perspectives will not be considered in this paper.

The perspectives of parents and health professionals may play an important role in shaping children's engagement with technology. For example, negative parental views on technology have been associated with more restrictive mediation strategies, whereas positive parental views have been linked to greater integration of technology into children's lives [23]. Likewise, health professionals with a positive view on technology may encourage parents to actively engage with their children's technology use, whereas those with a negative view may highlight the potential health risks associated with technology.

Perspectives can be captured through both qualitative and quantitative methods, such as interviews and questionnaires. While qualitative methods can provide a detailed understanding of perspectives, they are typically limited in sample size and generalizability. Given the low participant burden of questionnaires [24], this method enables large-scale data collection, which is essential for comparison of perspectives across different population groups. While questionnaires are useful tools, their validity is crucial for ensuring accurate and reliable high-quality evidence. However, no study has systematically investigated questionnaires that have been developed and used for assessing adults' perspectives on children's technology use and the validity of these tools. Thus, the focus of this study was on questionnaires. Having valid questionnaires available for capturing such perspectives can aid in developing evidence-based strategies for supporting adults in moving toward perspectives and practices that help children to thrive in a digital world.

Therefore, the primary aim of this systematic review was to investigate the psychometric properties of questionnaires that have been used to assess parents' and health professionals' perspectives on young children's use of technology related to health, well-being, and development. A secondary aim was to summarize the perspectives of parents and health professionals on young children's use of technology as measured by these tools.

Methods

Study Protocol

The study protocol was prospectively published on Open Scientific Framework [25]. This systematic review adhered to the PRISMA (Preferred Reporting Items for Systematic Review and Meta-Analyses) [26] (Checklist 1).

RenderX

Ethical Considerations

This systematic review was exempted from ethics or institutional review board approval, as it did not involve human participants, and ethics approval was not required to review published or publicly reported literature.

Search Strategy

Searches were conducted in the following electronic databases: CINAHL, Embase, MEDLINE, ProQuest, PsycInfo, Scopus, SPORTDiscus, and Web of Science (Core Collection). These databases were selected to ensure coverage across multiple research disciplines relevant to the review topic, that is, health and medical sciences (MEDLINE and Embase), psychology and behavioral sciences (PsycInfo), nursing and allied health (CINAHL), as well as multidisciplinary sources (Scopus, Web of Science, and ProQuest). The search targeted papers published between January 1, 2010, and September 1, 2024, to capture contemporary technology and was conducted using a combination of search terms relating to adults' perspectives, technology use, target population (ie, parents, health professionals, and children), and method (ie, questionnaire). A full list of search strategies by databases is provided in Multimedia Appendix 1. Additionally, reference lists of included papers were searched for additional relevant studies.

Selection of Studies

All retrieved studies were exported into EndNote (version 20; Clarivate Analytics). Two reviewers (CLR and IPHA) independently screened titles and abstracts to identify potentially relevant papers using Research Screener, a software system that uses artificial intelligence to iteratively learn from screening decisions, reducing the need to review irrelevant papers [27]. Following title and abstract screening, full text screening of papers was completed independently by the same 2 reviewers. Any researcher disagreement on the eligibility of a particular study was resolved through discussion, with a third reviewer (JZ) to resolve discrepancies.

Inclusion Criteria

Studies were included if they explored parents' and health professionals' perspectives on young children's (aged birth to 5 years) technology use, including screen- and nonscreen-based devices, using questionnaires (eg, self-report survey instruments and diaries). Studies were included if they reported the use of a questionnaire relevant to the review aim, regardless of whether full details on the questionnaire and its development were reported. Only original peer-reviewed papers, published in English, were considered.

Exclusion Criteria

Review studies, expert opinions, editorial letters, and studies that focused on children with chronic health conditions (eg, cancer, diabetes, and epilepsy) were excluded.

Quality Assessment of Included Studies

The methodological quality of the included studies was assessed using the Quality Assessment Checklist for Survey Studies in Psychology (Q-SSP) [28]. The Q-SSP was selected, as it was specifically developed to evaluate the quality of survey-based studies, which aligned with the focus of this review. The Q-SSP was developed through a multistage process, which included reviewing existing quality assessment tools, establishing expert consensus on selected items, and refining the instrument based on validity assessments. The Q-SSP is a 20-item checklist that evaluates survey quality across 4 domains: introduction (4 items), participants (3 items), data (10 items), and ethics (3 items). Each item has the following response categories: yes (met criteria), no (did not meet criteria), not stated clearly, or not applicable. For each study, an overall quality score and a quality score for each domain were calculated as the percentage of "yes" out of the total applicable items. Depending on the number of applicable items, studies were required to achieve a set threshold score to be rated as "acceptable" in quality, while studies with scores less than this threshold were deemed to have "questionable" quality. Specifically, studies were classified as having "acceptable" methodological quality if they achieved an overall score ≥73% in accordance with the threshold defined in the Q-SSP [28]. The following were used as thresholds for "acceptable" quality for each domain as recommended: ≥75% for introduction, ≥67% for participants, ≥70% for data, and ≥100% for ethics. Of note, item 19 ("Were participants debriefed at the end of data collection?" ethics domain) was considered as not applicable, as debriefing could be argued as being impractical and that the data collection was harmless, given that all included studies were based on questionnaires. Study quality was independently assessed by 2 reviewers (CLR and IPHA), and any discrepancies were resolved by discussion without the requirement of a third reviewer.

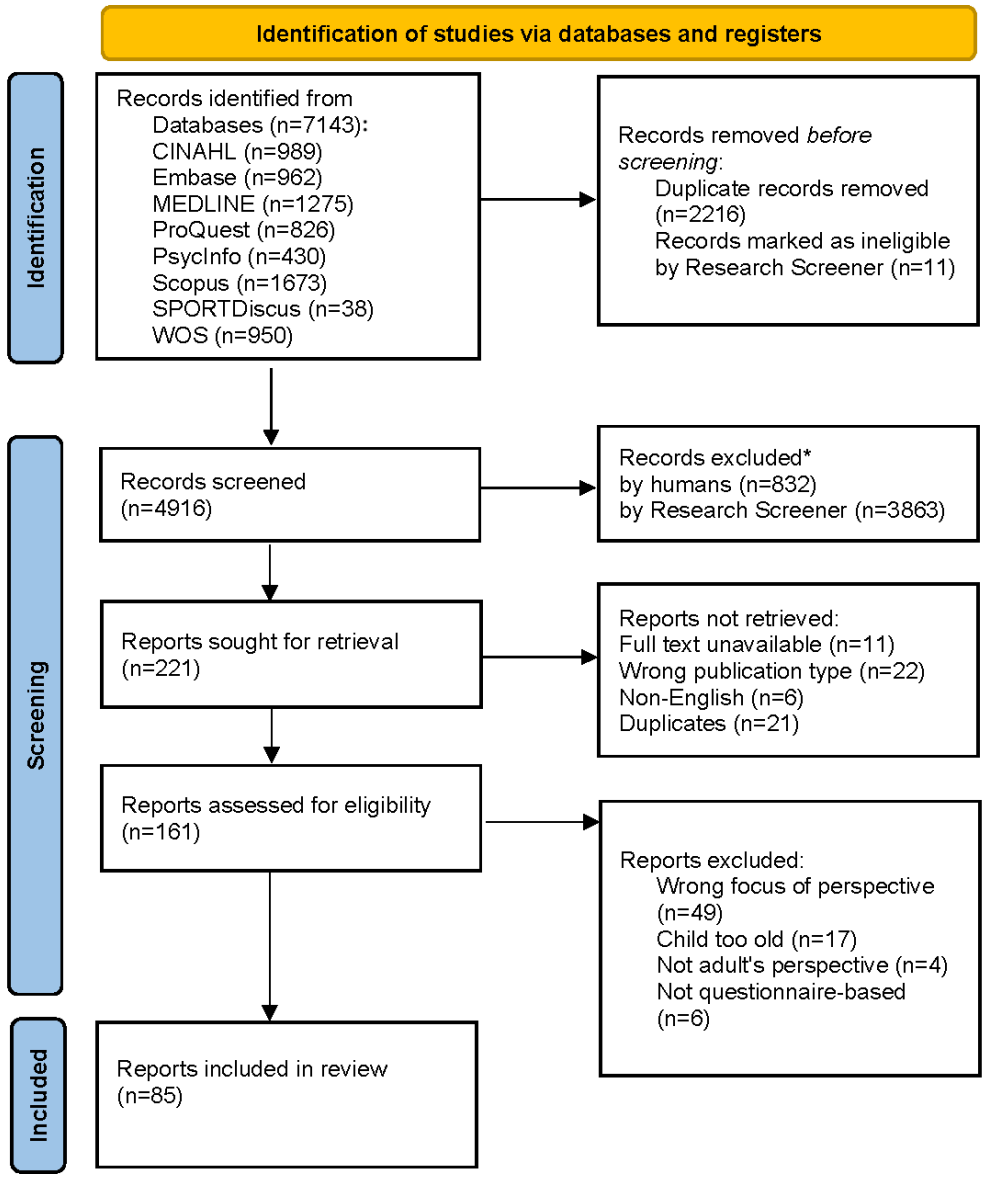
Data Extraction and Synthesis of Studies Included in the Review

The following data were extracted from the included studies: study characteristics, questionnaire characteristics, questionnaire items, and perspectives from study participants. Study characteristics included author, year of publication, country where the study was completed, country setting (ie, country income classification), study aim and design, sample sizes, sample characteristics, and recruitment strategy. Sample characteristics included age, gender identity, and relationship to the child. Information on the following questionnaire details was extracted: questionnaire details (ie, title, number of items, and administration format), questionnaire development, number of items and scoring details, and questionnaire psychometric properties.

Reported psychometric properties of the questionnaires were descriptively synthesized. When available, this included evidence of validity (ie, face validity, content validity, construct validity, and criterion validity) and reliability (ie, internal consistency and test-retest reliability). Questionnaire items related to adults' perspectives on children's technology use and the reported perspectives were extracted from each study and entered into NVivo (version 14; QSR International) [29] to facilitate coding and identification of common themes related to the focus of the questionnaires and reported perspectives. All data were extracted independently by 2 reviewers (CLR and IPHA) and cross-checked for any discrepancies, which were resolved without requiring a third reviewer.

XSL•FO
RenderX

A 2-level coding framework was developed to systematically assess (1) technology type, that is, technologies the questionnaire referred to, and (2) questionnaire content focus, that is, the focus of the items within the questionnaire regarding adults' perspectives on children's technology use. Following this framework, each questionnaire was first coded based on the technology type it referred to using the following codes (level 1): applications, computer, digital media or digital device, gaming, mobile touch screen devices, no specific hardware, screen time, and television. Next, a deductive thematic analysis [30] was used to investigate the content focus of each item and the reported perspectives, which were classified into 4 key dimensions based on the child-technology interaction model [14] to facilitate reader understanding:



- Child: characteristics of the child, including demographic factors and individual capabilities (eg, age, physical health, and cognition);
- Other people: the role of family members or other social influences, such as peers and siblings, in children's technology use (eg, family interaction and coviewing);
- Tasks: the purpose for which the technology is used (eg, learning and entertainment); and
- Technology: the nature of the technology involved (eg, software and content).

Results

Study Inclusion

Figure 1 shows the PRISMA flowchart of search results and study exclusions. A total of 7143 records were identified based on the initial database search, of which 85 studies met the inclusion criteria for this review.

Figure 1. PRISMA flowchart of included studies. *Screening took place using "Research Screener," an artificial intelligence screening software. Four records were considered ineligible by Research Screener due to a lack of abstracts. In total, 21 rounds of screening (50 in each round) took place before the screeners determined that no further useful papers were being shown. PRISMA: Preferred Reporting Items for Systematic Reviews and Meta-Analyses.

XSL•FO
RenderX

Quality Assessment of Included Studies

Results of the quality assessment are presented in Table S1 in Multimedia Appendix 2 [31-115]. The average overall quality score was 61% (SD 15%; range 32% - 100%), with 62 studies scoring below the threshold for acceptable quality (ie, 73%), indicating questionable quality. Generally, studies had higher quality scores for introduction, as 84 studies scored above the threshold for acceptable quality (overall mean 98%, SD 8%; range 50% - 100%). In total, 47 and 17 studies, respectively, had acceptable quality related to information about study participants (mean 49%, SD 26%; range 0% - 100%) and data (mean 49%, SD 19%; range 10% - 100%). A total of 49 studies provided acceptable quality information related to ethics (mean 60%, SD 48%; range 0% - 100%).

Characteristics of Included Studies

The characteristics of included studies are provided in Table 1. Studies were published between 2012 and 2024, with most studies published in 2022 (11/85, 13%) and 2023 (22/85, 26%). Only 3 studies aimed to explicitly develop and validate questionnaires for measuring parents' perspectives on children's use of technology [33,39,112]. Among the remaining studies, most studies aimed to investigate adults' perspectives of children's use of technology (48/85, 56%) and/or determinants of children's technology use (19/85, 22%).

XSL•FO

Table . Characteristics of the included studies.

Author, year, country, country setting[a]	Aim of study	Study design and measurement type	Participants' characteristics (sample size; relationship to child; gender[b]; age)	Recruitment strategy
Akyol (2022) [31], Turkey, UMIC[c]	To investigate the effect of an online education program on parents' views on their children's technology use and online education.	Unclear if results are based on cross-sectional or longitudinal measurements. Mixed method (questionnaire and case study).	20; parents; 50% women; age NR[d].	NR.
Aladé and Donohue (2023) [32], United States, HIC[e]	To investigate the relationships between children's at-home technology use, their parents' attitudes toward technology, and their in-school tablet use.	Longitudinal. Mixed method (questionnaire and case study).	258; parents; 78% women; age NR.[d]	Parents were recruited from kindergartens that participated in a project where urban schools were given a tablet to use in the classroom.
Al-Balushi and Al-Shihi (2016) [33], Oman, HIC	To investigate parents' awareness of the risks of mobile devices on children and their happiness about their children's mobile device use.	Cross-sectional. Mixed method (explorative case study and questionnaire validity study).	10; parents; gender NR; age NR.	NR.
Alkalash et al (2023) [34], Saudi Arabia, HIC	To investigate parents' knowledge, attitudes, and practices of regulating screen exposure among their 6-year-old children in Saudi Arabia.	Cross-sectional. Questionnaire-based.	451; parents; 64% women; 35% aged between 25 and 34 years.	NR.
AlSamhori et al (2025) [35], Jordan, UMIC	To investigate parents' awareness of their 4 - to 10-year-old children's electronic device use and their perspectives on how screen time affects children's behavior in Jordan.	Cross-sectional. Questionnaire-based.	807; parents; gender NR; mothers' mean age was 35 (SD 5) years, fathers' mean age was 39 (SD 6) years.	Parents were recruited through various methods, including social media platforms and the distribution of the questionnaire in paper format at different locations in Jordan.
Amzalag (2021) [36], Israel, HIC	To investigate (1) parents' perceptions about digital learning games and 21st century skills and (2) parents' attitudes toward digital learning games instead of traditional homework.	Cross-sectional. Mixed method (questionnaire and semistructured interview).	198; parents; 71% women; age NR.	NR.
Arippin et al (2023) [37], Brunei Darussalam, HIC	To investigate parents' knowledge, attitude, practice, and experience of the screen time spent by their children younger than 5 years of age at home and to identify the common screen-based devices used, content type, and level of screen time spent by the children.	Cross-sectional. Questionnaire-based.	113; parents; 91% women; age NR.	Parents were recruited through health care facilities in 4 districts in Brunei Darussalam.

XSL•FO
RenderX

Author, year, country, country setting[a]	Aim of study	Study design and measurement type	Participants' characteristics (sample size; relationship to child; gender[b]; age)	Recruitment strategy
Asplund et al (2015) [38], United States, HIC	To investigate (1) the rates of adherence to the American Academy of Pediatrics (AAP) screen time guidelines among Latino parents, (2) parental attitudes toward childhood electronic media use, and (3) the associations of child BMI, child and parent demographic characteristics, and household media environment with adherence to AAP screen time guidelines and with parents' attitudes toward childhood media use.	Cross-sectional. Questionnaire-based.	302; parents; gender NR; 47% younger than 30 years.	Families with an appointment at a clinic offering a nutrition program for women, infants, and children were contacted by study staff and asked to complete a survey.
Balaban Dağal and Bayındır (2019) [39], Turkey, UMIC	To develop a scale, "Effects of Digital Games in Early Ages Scale," which aimed to evaluate the effects of digital games on children during early childhood according to parental perception.	Cross-sectional. Questionnaire validation study.	777; parents; gender NR; age NR.	Families were recruited from 14 randomly selected schools with lower, middle, and upper socioeconomic status.
Bansal et al (2023) [40], India, LMIC[f]	To investigate the exposure of media and its influence among children.	Cross-sectional. Questionnaire-based.	405; parents; 63% mothers; age NR.	NR.
Barmomanesh et al (2017) [41], New Zealand, HIC	To investigate the use of touch screen devices in particular tablets or smartphones among 0 - to 5-year-old children and to ascertain parents' insights toward the use of these types of technologies by their children.	Cross-sectional. Questionnaire-based.	166; parents; 95% women; age NR.	Parents were recruited through a parenting Facebook page. An announcement containing a direct link to the survey was also sent by a manager at an education center to invite parents for participation in the survey.
Beyens and Eggermont (2014) [42], Belgium, HIC	To investigate predictors and consequences associated with the use of television as a "babysitter" for young children.	Cross-sectional. Questionnaire-based.	844; parents; 88% women; mean age 36 (SD 4.70) years.	Parents were recruited via invitation letters sent to 47 kindergartens and childcare centers.
Bleakley et al (2013) [43], United States, HIC	To investigate determinants and beliefs associated with parents' intention to limit their children's television viewing.	Cross-sectional. Based on telephone surveys.	516; parents; 67% women; mean age of 41 (SD 9.7) years.	Parents were selected using a random digit dialing from a publicly available list of households with a greater likelihood of containing a child between 3 and 16 years.
Boonmun et al (2023) [44], Thailand, UMIC	To investigate the effects of a training program on parents' planned behaviors and screen time reduction of their children.	Quasi-experimental study. Questionnaire-based.	67; parents; gender NR; mean ages were 27 years in the control group and 30 years in the intervention group.	Parents were recruited from 2 childcare centers in Thailand.
Bourha et al (2024) [45], Greece, HIC	To investigate parental perspectives on using digital technologies and the use of technology-enhanced toys among their 1 - to 4-year-old children.	Sequential explanatory study (dual phase: pre- and postinteraction with technology-enhanced toys). Questionnaire-based.	Prequestionnaire: 78; parents; 81% women; 59% were between 30 and 40 years. Postquestionnaire: 59; parents; 86% women; 66% were between 30 and 40 years.	Parents were recruited from 5 childcare centers.

RenderX

Author, year, country, country setting[a]	Aim of study	Study design and measurement type	Participants' characteristics (sample size; relationship to child; gender[b]; age)	Recruitment strategy
Brauchli et al (2024) [46], Switzerland, HIC	To investigate the roles of parenting stress and attitudes toward children's screen time throughout early childhood.	Longitudinal. Questionnaire-based.	462; parents; 93% women; mean ages were 36 - 37 (SD 4) years across 4 measurement time points.	Parents were recruited through newsletters from nonprofit organizations, posts in social media, advertisements in parenting magazines, and flyers distributed at daycare centers, pediatricians, and parental counseling centers.
Brown et al (2023) [47], United States, HIC	To investigate (1) parental knowledge and educational interests, (2) parental motivation or self-efficacy, and (3) parental beliefs about digital media use and determine how these vary based on children's age.	Cross-sectional. Questionnaire-based.	611; parents and grandparents; 77% women; mean age of 36.2 years (95% CI 35.4 - 37.1).	Parents from one of the pediatric practices associated with a statewide pediatric clinical trials and research network for their children's wellness appointment were offered to participate in the study by filling out a paper survey containing a description of the project.
Cardy et al (2023) [48] Canada, HIC	To investigate the patterns and purposes of technology use among autistic children compared to nonautistic children, explore how technology use affects children's well-being, and examine parents' attitudes toward children's technology use.	Cross-sectional. Questionnaire-based.	611; parents; gender NR; age NR.	Parents were recruited via hospital social media channels, newsletters and email distribution lists, and word-of-mouth.
Carson and Janssen (2012) [49], Canada, HIC	To investigate the influence of intrapersonal, interpersonal, and physical environment factors within the home setting on screen time among 0 - to 5-year-old children.	Cross-sectional. Questionnaire-based.	746; parents; 92% women; age NR.	Parents with children ≤5 years were recruited from licensed childcare centers and public health or community programs.
Carson et al (2013) [50], Canada, HIC	To investigate the proportion of 0 - to 4-year-old children meeting the new Canadian Sedentary Behaviour Guidelines for the Early Years and to describe parental attitudes toward and barriers to reducing screen time.	Cross-sectional. Questionnaire-based.	657; parents; gender NR; age NR.	Parents of preschool children were recruited from childcare centers and public health or community programs.
Chattha et al (2021) [51], Pakistan, LMIC	To investigate daily screen time among 2 - to 5-year-old children along with predisposing factors, quality of screen time, and parental perceptions of their children's screen time.	Cross-sectional. Mixed method (interview and questionnaire-based).	200; parents; gender NR; age NR.	Parents were recruited from general outpatient departments and pediatric outpatient departments of hospitals.
Chia et al (2022) [52], Singapore, HIC	To investigate the relationship between parent and child digital media use and to compare the characteristics of the top and bottom quartiles of children's daily digital media use.	Cross-sectional. Questionnaire-based.	1481; parents; 79% women; age NR.	Parents of children aged 2 - 5 years were recruited from preschools via invitation letters sent by the preschool operator.

XSL•FO

Author, year, country, country setting[a]	Aim of study	Study design and measurement type	Participants' characteristics (sample size; relationship to child; gender[b]; age)	Recruitment strategy
Chen and Tu (2018) [53], Taiwan, HIC	To investigate the impact on parents' attitudes toward internet use and their expectations of preschools to use internet-related applications.	Cross-sectional. Questionnaire-based.	483; parents; 71% women; 67% were aged 31 - 40 years.	NR.
Cingel and Krcmar (2013) [54], United States, HIC	To investigate how parent and child demographics, parental media-use motives, parental subjective norms, and parental attitudes toward preschool media use relate to actual media exposure among children.	Cross-sectional. Questionnaire-based.	168; parents; 85% women; age NR.	Parents were recruited from daycare centers, organized parent groups, and via an online snowball sample, where a link to an online version of the survey was sent to a number of parents who forwarded the link to others.
Covolo et al (2021) [55], Italy, HIC	To investigate (1) adults' opinions about mobile device use among 0 - to 5-year-old children, (2) if being parents of young children increased risk perception, and (3) the relationship between risk perception and parental attitudes to their children's mobile device use.	Cross-sectional. Questionnaire-based.	3115; parents; 86% women; mean age of 37.2 (SD 10.5) years.	Participants were recruited using a snowball sampling method by sharing a link of an online survey via social media and distributing the link through WhatsApp and Facebook groups dealing with children's health.
Dardanou et al (2020) [56], Norway, Portugal, and Japan, HIC	To investigate (1) parents' views on 0 - to 3-year-old children's use of touchscreen devices at home in Norway, Portugal, and Japan and (2) how dominant cultural discourses influence parents' perceptions and concerns regarding their 0 - to 3-year-old children's use of touchscreen devices.	Cross-sectional. Questionnaire-based.	552; parents; gender NR; age NR.	NR.
Dong et al (2022) [57], China, UMIC	To investigate (1) the average levels of young children's digital literacy and multimodal practices in central China, (2) the latent profiles of digital families in central China, and (3) the predictors of young children's digital literacy and multimodal practices in central China.	Cross-sectional. Questionnaire-based.	1953; parents and grandparents; 80% women; 39% aged between 31 and 35 years.	Online invitations were sent to all parents of children aged 0 - 8 years in a province in central China using an online survey platform. Furthermore, kindergarten principals, teachers, educators, and researchers advertised the online survey via social networks.
Eales et al (2021) [58], United States, HIC	To investigate (1) how children use screen media differently pre- versus post–COVID-19 and parent perceptions of their child's media use and (2) the parent and child factors that moderate trajectories of change in screen media use.	Longitudinal. Questionnaire-based.	129; parents; 98% women; mean age of 39.4 (SD 4.34) years.	Parents of children aged 2 - 11 years were randomly selected from a city-wide participant pool and sent an email with a survey link. Parents who indicated that they were willing to be recontacted were sent a follow-up mail with an invitation to complete another survey.

Author, year, country, country setting[a]	Aim of study	Study design and measurement type	Participants' characteristics (sample size; relationship to child; gender[b]; age)	Recruitment strategy
Ebbeck et al (2016) [59], Singapore, HIC	To investigate (1) which technological devices are used by 0 - to 7-year-old children in Singapore, (2) the time duration spent on using different technological devices by 0 - to 7-year-old children in Singapore, and (3) parents' views of risks and benefits of their children accessing the emerging touch screen devices.	Cross-sectional. Questionnaire-based.	1058; parents; 72% women, 69% aged between 31 and 40 years.	Information letters were sent to parents or caregivers by email and hard copy to principals of 34 childcare centers.
Fan et al (2023) [60], China, UMIC	To investigate the parental perspectives of 2 - to 6-year-old children's use of short-video mobile apps.	Cross-sectional. Mixed method (questionnaire and interviews).	266; parents; 68% women; 73% were aged between 30 and 40 years.	Parents were recruited from an online survey service.
Farima et al (2023) [61], Moldova, UMIC	To investigate parents' knowledge, attitudes, and practices regarding the use of electronic devices by preschool children.	Cross-sectional. Questionnaire-based.	422; parents; 87% women; 63% were aged between 26 and 35 years.	NR.
Garcia-Conde et al (2020) [62], Spain, HIC	To investigate how parental attitudes toward sleeping, screen use, and feeding their child influence the child's body mass index.	Cross-sectional. Questionnaire-based.	908; parents; 84% women; age NR.	Parents were recruited from 21 primary schools in the main cities.
Gjelaj et al (2020) [63], Kosovo, UMIC	To investigate preschool teachers' and parents' attitudes and practices regarding digital technology use during preschool education.	Cross-sectional. Mixed method (questionnaire filled out by parents and teachers, and interviews).	100; parents; gender NR; age NR.	Parents and teachers were recruited from preschools by random sampling.
González-Sanmamed et al (2023) [64], Spain, HIC	To investigate families' perspectives on their children's use of mobile devices.	Cross-sectional. Questionnaire-based.	241; parents; 73% women; mean age was 39 (SD 7) years.	Parents were recruited from schools.
Grané et al (2023) [65], Spain, HIC	To investigate how and in what way families' perceptions and beliefs about digital technologies modulate children's use of screens at home.	Cross-sectional. Mixed method (questionnaire and interview).	46; parents; 76% women; age NR.	NR.
Griffith et al (2025) [66], United States, HIC	To investigate parents' experiences with remote schooling and technology-facilitated homework and how family characteristics, parent attitudes toward screen media, and parent digital skills relate to experiences with remote schooling and attitudes toward the use of digital technology for homework.	Cross-sectional. Questionnaire-based.	822; parents; 82% women; mean age was 36 (SD 9) years.	Parents were recruited from online panels via web-based advertising, customer loyalty web portals, and targeted email lists.

Author, year, country, country setting[a]	Aim of study	Study design and measurement type	Participants' characteristics (sample size; relationship to child; gender[b]; age)	Recruitment strategy
Halpin et al (2021) [67], Australia, HIC	To investigate relationships between parenting style, self-efficacy, child behavior, parent distress, and screen time in young children, and to identify important variables predicting self-efficacy for managing children's screen time and actual screen use in young children.	Cross-sectional. Questionnaire-based.	106; parents; 95% women; mean age 33.76 (SD 5.35) years.	Parents were recruited via advertisements on social media, parenting forums and websites, and emails sent out to childcare centers.
Hamilton et al (2016) [68], Australia, HIC	To investigate the decision-making process and the beliefs underpinning parents' decisions to ensure that their child's screen time is limited according to the guidelines developed by the Department of Health, Australia.	Longitudinal. Mixed method (questionnaire and telephone interview).	207; parents; 67% women; mean age of 36.38 years.	Participants were recruited via online sources, face-to-face recruitment, and through their child's daycare facility.
Hatzigianni et al (2014) [69], Australia, HIC	To investigate parents' beliefs about how and why their young children use computers.	Longitudinal. Questionnaire-based.	51; parents; gender NR; age NR.	Parents were recruited from primary schools and childcare centers, where the teachers were willing to participate in a computer intervention.
Howie et al (2020) [70], Australia and United States, HIC	To investigate the reliability and validity of the "Parent report and Adult versions of Technology Use Questionnaire" and describe the technology use among young children and their parents.	Cross-sectional. Questionnaire-based.	96; parents; 89% women; mean age 36.9 (SD 5.0) years.	Parents were recruited from not-for-profit childcare organizations and childcare centers from 2 different cities.
Hutton et al (2018) [71], United States, HIC	To investigate attitudes and behaviors regarding shared reading and infant television viewing during the perinatal period among low socioeconomic status mothers.	Longitudinal. Questionnaire-based.	282; parents; 100% women; mean age 22.9 (SD 4.6) years.	All mothers were enrolled in a randomized controlled trial of safe sleep education.
Ihmeideh and Alkhawaldeh (2017) [72], Jordan, UMIC	To investigate the perceptions of preschool teachers and parents on how technology and digital media contribute toward developing child culture in Jordanian early years education.	Cross-sectional. Mixed method (questionnaire and interview).	480; teachers (n=170) and parents (n=310); gender NR; age NR.	Preschool teachers and parents of children were recruited randomly from a list of all private kindergartens.
Ilgar and Karakurt (2018) [73], Turkey, UMIC	To investigate the general attitudes of mothers of preschoolers toward the impact of computer games on children's development and behavior.	Cross-sectional. Questionnaire-based.	749; parents; 100% women; age NR.	NR.
Istenič et al (2023) [74], Slovenia, HIC	To investigate Slovene parents' opinions and perceptions of play and how they structure their child's play by offering them a set of toys.	Cross-sectional. Questionnaire-based.	306; parents; 90% women; age NR.	NR.

XSL•FO
RenderX

Author, year, country, country setting[a]	Aim of study	Study design and measurement type	Participants' characteristics (sample size; relationship to child; gender[b]; age)	Recruitment strategy
Istenič et al (2023) [75], Slovenia, HIC	To investigate how parents (1) perceive digital technology and its role in a child's development and learning, (2) perceive characteristics of a child's play with traditional and digital toys, and (3) construct the home environment and play regarding a share of digital play versus traditional.	Cross-sectional. Questionnaire-based.	306; parents; 90% women; age NR.	NR.
Jain et al (2023) [76], India, LMIC	To determine the prevalence and predictors of excessive screen viewing time in children and its effect on physical or outdoor activity, sleep, and the prevalence of eye symptoms and headache in children in India.	Cross-sectional. Questionnaire-based.	Parents of 600 children answered a questionnaire when the children were younger than 10 years but unclear how many parents answered the questionnaire; parents; gender NR; age NR.	Households with children aged 3 - 15 years were identified during house-to-house visits in 36 urban wards and 36 villages using a 3-stage cluster sampling method.
Jin (2013) [77], Korea, HIC	To investigate (1) the relationship between 5 types of parental internet content filtering software (ICFS) adopters and the parents' adoption of ICFS, (2) how adoption type affects parents' perception of and satisfaction with ICFS, and (3) parental attitudes toward their children's internet use.	Cross-sectional. Questionnaire-based.	784; parents; 51% women; 69% aged 40 - 49 years.	Parents were randomly selected through consumer panel data on ICFS users. Active panel members were contacted by email and phone and asked to participate.
Joginder Singh et al (2021) [78], Malaysia, UMIC	To investigate (1) the amount of screen time reported by parents of 3 - to 5-year-old children, (2) how parental perception of screen time affects their children's language skills, and (3) the association between reported screen time and parental perceptions of how screen time affects their children's language skills.	Cross-sectional. Questionnaire-based.	340; parents; 85% women; 70% aged 31 - 40 years.	Parents were recruited online through WhatsApp, Telegram, and Facebook groups.
Konok et al (2020) [79], Hungary, HIC	To investigate whether parents' digital parenting style, general attitude, and beliefs regarding early mobile touch screen device use and role-modeling as indicated by their mobile attachment and use are associated with child digital activity.	Cross-sectional. Questionnaire-based.	1270; parents; 83% women; mean age 35.41 (SD 5.06) years.	Parents were recruited online through Facebook and the website of a Hungarian online magazine.
Kostyrka-Allchorne et al (2017) [80], United Kingdom, HIC	To investigate (1) media preferences and use among young children and (2) parental supervision methods and beliefs about media.	Cross-sectional. Questionnaire-based.	90; parents; 91% women; age NR.	Parents were recruited from 2 primary schools and 4 preschools.

XSL•FO

Author, year, country, country setting[a]	Aim of study	Study design and measurement type	Participants' characteristics (sample size; relationship to child; gender[b]; age)	Recruitment strategy
Lee et al (2022) [81], Korea, HIC	To investigate the association between young children's media use and parents' media use, attitudes toward media, and parenting style.	Cross-sectional. Questionnaire-based.	1020; parents; 50% women; age NR.	Parents were recruited from a national panel pool by a Korean survey company.
Lepicnik-Vodopivec and Samec (2013) [82] Slovenia, HIC	To investigate (1) how many types of information-communication technology (ICTs) the child's family owns, (2) the nature of the child's access at home, (3) how the child uses ICTs at home, (4) how often the child uses ICTs at home, (5) the influences on the child's use of ICTs at home, (6) the influence of the child's ICT use on their development, (7) the child's attitude toward ICTs at home, and (8) the parents' awareness about ICT use.	Cross-sectional. Questionnaire-based.	130; parents; 84% women; age NR.	NR.
Li and Chen (2015) [83], China, UMIC	To investigate how preschool children use tablets and the extent to which their parents' media behavior influences the children's tablet use.	Cross-sectional. Mixed method (questionnaire and interview).	161; parents; gender NR; age NR.	Parents were recruited from 3 kindergartens.
Liibaan et al (2023) [84], Scotland, HIC	To investigate parents' opinions of screen time, including impact on children's sleep, behavior, development, and underlying factors surrounding use and awareness of national guidelines.	Cross-sectional. Mixed method (questionnaire and interview).	9; parents; gender NR; age NR.	Parents were recruited via social media posts.
Little (2019) [85], United Kingdom, HIC	To investigate heritage language families' attitudes to using game-based digital technology for heritage language and literacy development, and how these attitudes are associated with children's self-awareness as heritage language speakers.	Cross-sectional. Mixed method (questionnaire and interview).	212; parents; gender NR; age NR.	Parents were recruited via social media posts, posted in 6 online parenting groups linked to heritage language or bilingualism.
Luo et al (2023) [86], Taiwan, HIC	To investigate parents' attitudes toward their young children's use of information communication technology, use patterns, and the relationship with socioeconomic status.	Cross-sectional. Questionnaire-based.	629; parents; 78% women; 40% were aged between 36 and 40 years.	Parents were recruited via kindergartens and elementary schools using a convenience sampling technique.

Author, year, country, country setting[a]	Aim of study	Study design and measurement type	Participants' characteristics (sample size; relationship to child; gender[b]; age)	Recruitment strategy
Mansor et al (2021) [87], Malaysia, UMIC	To investigate parental barriers toward reducing a child's screen time and its predictors from sociodemographic, parental, child-related, and environmental factors among parents of children younger than 5 years of age who attended a child health clinic in Malaysia.	Cross-sectional. Questionnaire-based.	789; parents; 84% women, mean age 31.6 (SD 4.8) years.	Parents were recruited from 9 health clinics based on an attendance record from each clinic.
Matziou et al (2021) [88], Greece, HIC	To investigate (1) preschool children's sleeping and television viewing habits, (2) parents' perceptions about television viewing, and (3) potential correlation between the 2.	Cross-sectional. Questionnaire-based.	100; parents; gender NR; mean age of fathers 37.4 (SD 4.4) years, mean age of mothers 32.9 (SD 4.0) years.	Parents were recruited from randomly selected kindergartens.
Mikelić Preradović et al (2016) [89], Croatia, HIC	To investigate (1) perceptions of parents in Croatia toward computer use in general and their children's computer use and (2) parents' concerns and opinions about digital technology education in kindergarten.	Cross-sectional. Questionnaire-based.	152; parents; 72% women; 64.4% were aged 30 - 39 years.	Parents were recruited from a public early childhood educational institution.
Milford et al (2022) [90], Australia, HIC	To investigate how parents access information related to mobile media and their perspectives about the impact of mobile media on their child's behavior and executive functioning.	Cross-sectional. Questionnaire-based.	213; parents and other caregivers; 95% women; 45% were aged 31 - 40 years.	Parents or caregivers were recruited by posting advertisements on social media platforms including Facebook and Twitter and promoting within the community.
Nabi and Krcmar (2016) [91], United States, HIC	To investigate how perceived child characteristics influence parents' motives for allowing their children to use screen media.	Cross-sectional. Questionnaire-based.	151; parents; 82% women; age NR.	Parents were recruited from daycare centers, organized parent groups, and online snowball sampling, in which a link to the online version of the survey was sent to several parents, who then forwarded the link to others. The survey link was also posted on social networking sites.
Natsiopoulou et al (2013) [92], Greece, HIC	To investigate Greek parents' views on integrating computers into the preschool classroom and how they relate to family socioeconomic background.	Cross-sectional. Questionnaire-based.	280; parents; gender NR; age NR.	Parents were recruited from private and municipal preschool centers.
Nikken (2019) [93], Netherlands, HIC	To investigate whether parents see media devices as useful tools in child-rearing, and how parent-family characteristics and parental perceptions on parenting, media effects, and child development predict the acceptance of instructional media use.	Cross-sectional. Questionnaire-based.	516; parents; 68% women; age NR.	Parents were recruited online by a professional marketing research bureau.

Author, year, country, country setting[a]	Aim of study	Study design and measurement type	Participants' characteristics (sample size; relationship to child; gender[b]; age)	Recruitment strategy
Nikken and Schols (2015) [94], Netherlands, HIC	To investigate if children's media skills and activities, parents' attitudes about media for children, and other child and parent characteristics predicted parental mediation practices.	Cross-sectional. Questionnaire-based.	896; parents; 47% women; mean age 37.3 (SD 6.1) years.	Parents were recruited from a large online panel.
Njoroge et al (2013) [95], United States, HIC	To investigate the associations between race or ethnicity, family socioeconomic status, and child television or DVD viewing, while assessing differences in ethnically diverse parents' beliefs and attitudes regarding the impact of television or DVD viewing on early childhood development.	Cross-sectional. Questionnaire-based.	596; parents; gender NR; age NR.	Parents were recruited from 2 metropolitan Seattle pediatric clinics and a pediatric practice network. Letters describing the study were sent to families with 3 - to 5-year-old children without regard to whether the child had been seen in their pediatric clinic recently.
Nwankwo et al (2019) [96], United Kingdom, HIC	To investigate the drivers of screen-related sedentary behavior within the home context and parents' attitudes in supporting children's associated behavior.	Cross-sectional. Mixed method (questionnaire and interview).	140; parents; 58% mothers; 49% were aged 36 - 45 years.	Parents were recruited by sending a survey link through emails or social media groups (Facebook, WhatsApp, and Twitter).
O'Connor and Fotakopoulou (2016) [97], United Kingdom, HIC	To investigate (1) what 0 - to 3-year-old children are doing with touch-screen devices in UK families, (2) what parents perceive as the advantages and drawbacks of their 0 - to 3-year-old children using new technology, and (3) the extent to which the justification of their practices appears to be aligned with dominant discourses around young children and technology.	Cross-sectional. Questionnaire-based.	226; parents and grandparents; 90% women; 67% were aged 31 - 40 years.	Parents were recruited by sending the online questionnaire to personal, parenting, and professional networks.
Ophir et al (2023) [98], Israel, HIC	To investigate the extent to which children's screen time increased during the COVID-19 lockdown and to evaluate mothers' consequent negative emotional reactions (study 1); and to investigate what could be contributing to the increases in screen time (study 2).	Cross-sectional with 2 independent cohorts. Questionnaire-based.	Study 1: 299; mothers; mean age was 41 (SD 5) years. Study 2: 283; mothers; mean age was 37 (SD 6) years.	Mothers were recruited from a survey company in Israel (study 1) and an Israeli college (study 2).
Van Petegem et al (2019) [99], Belgium, HIC	To investigate associations between parents' degree and style of restrictive mediation of children's digital gaming and parents' attitude about digital gaming, perceptions of children's defiance and problematic gaming, and their interest in social play.	Cross-sectional. Questionnaire-based.	762; parents; 83% women; mean age 35.27 (SD 5.65) years.	A large-scale survey was distributed through the mailing list of a child-oriented entertainment company. Parents with a child aged between 3 and 9 years were invited to participate.

Raj et al (2022) [100], Malaysia, UMIC	To investigate the prevalence and determinants of excessive screen time among children younger than 5 years in Selangor, Malaysia.	Cross-sectional. Questionnaire-based.	489; parents; 48% women; mean age 32.2 (SD 0.2) years.	Parent-child dyads were recruited from 9 child health clinics.
Raj et al (2023) [101], Malaysia, UMIC	To develop, implement, and evaluate the effectiveness of a digital parental health education intervention to reduce excessive screen time among preschoolers from low socioeconomic families in Malaysia.	Randomized controlled trial. Questionnaire-based.	360; mothers; mean ages were 34 (SD 4.3) years in the intervention group and 33 (SD 5) years in the control group.	Mothers were recruited from preschools via electronic pamphlets containing information about the study. Interested mothers self-registered for the study using a Google Form link.
Rajalakshmi et al (2023) [102], India, LMIC	To investigate the burden of digital screen exposure and parental perceptions of its effects in children.	Cross-sectional. Questionnaire-based.	140; caregivers; 84% women; age NR.	Adults were recruited from tertiary health care centers using a random sampling technique.
Rosanda et al (2022) [103], Slovenia, HIC	To investigate (1) the use of digital technology by Slovenian infants and toddlers younger than 2 years of age, (2) what types of digital devices and apps young children use in their play, and (3) the parents' perspectives about their children's use of digital devices.	Cross-sectional. Questionnaire-based.	26; 25 parents and 1 aunt; gender NR; mean age 33.5 (SD 4.3) years.	NR.
Sada Garibay and Lapierre (2024) [104], Mexico, UMIC	To investigate what drives parents to use technical restriction tools offered by Subscription Video on Demand services.	Cross-sectional. Questionnaire-based.	1022; parents; 65%women; 44% were aged between 41 and 50 years.	Parents were recruited via Facebook, Instagram, student WhatsApp accounts, and other social media.
Peštaj et al (2024) [105], Slovenia, HIC	To investigate parental views on the characteristics of a quality children's program and its positive and negative effects on children's development and learning.	Cross-sectional. Questionnaire-based.	239; parents; 88% women; mean age was 34.9 (SD 5.24) years.	Parents were recruited via Facebook and emails by a counselor in the preschool where their children were enrolled.
Solomon-Moore et al (2017) [106], United Kingdom, HIC	To investigate whether parents' attitudes toward their young child's screen viewing behavior are associated with parents' sedentary time and screen viewing behaviors.	Cross-sectional. Questionnaire-based.	809; parents; 74% women; age NR.	Child-parent dyads were recruited from 57 primary schools in the greater Bristol area.
Stuckelman et al (2023) [107], United States, HIC	To investigate the inclusion of parent-directed suggestions or "nudges" in a touchscreen game app to promote positive shared family interactions during digital coplay.	Randomized controlled trial. Questionnaire-based.	77; parents; 92% women; control group mean age was 36.15 (SD 7.07) years, experimental group mean age was 35.45 (SD 6.74) years.	Parent-child dyads were recruited from social media posts, state birth records, and a university database of families interested in research participation.

Suresh and Tiwari (2023) [108], India, LMIC	To investigate the parental knowledge, attitudes, and concerns toward media technology and screen time use by preschool children with autism spectrum disorder (ASD) and typically developing (TD) children in the Indian context.	Cross-sectional. Questionnaire-based.	182; parents (92 parents of TD children, 90 parents of children with ASD); 83% women in TD group, 86% women in ASD group; parents in both groups were aged between 20 and 49 years.	Parents in the ASD group were recruited from department clinics, regular schools, special schools, parent groups for children with ASD, and private speech therapy clinics. Parents in the TD group were recruited through regular primary schools, preschools, and day care centers.
Tanusha et al (2023) [109], Malaysia, UMIC	To investigate parents' perception of digital device use among their preschool children.	Cross-sectional. Questionnaire-based.	139; parents; gender NR; age NR.	Parents were recruited from their children's kindergartens. In total, 10 government kindergartens were randomly selected, and 15 children were selected randomly by computer from each school using the student registry.
Tay et al (2021) [110], Singapore, HIC	To investigate parents' attitudes and concerns toward their preschoolers' use of technology and digital media in Singapore.	Cross-sectional. Questionnaire-based.	3413; parents; gender NR; age NR.	Parents were recruited via letters, with a QR code to scan and complete the survey, sent out by the research team.
Vaala and Hornik (2014) [111], United States, HIC	To investigate (1) the relationships between American infants' and toddlers' television or video viewing time and their mothers' demographics, structural life circumstances, and cognitions and (2) the extent to which mothers' cognitions mediate relationships between the structural circumstances of mothers' lives and their infants' or toddlers' estimated television or video viewing.	Cross-sectional. Questionnaire-based.	698; mothers; 100% women; mean age 28.5 (SD 6.6) years.	Mothers were recruited through a national panel of around 1 million members. The panel sent recruitment emails to panel members who fit the criteria for study participation.
Vaiopoulou et al (2021) [112], Greece, HIC	To investigate (1) the psychometric characteristics of the Perceptions about Educational Apps Use-parents (PEAU-p) instrument and (2) explore parents' perceptions and attitudes toward using educational apps by implementing the PEAU-p instrument.	Cross-sectional. Questionnaire validation study.	435; parents; 96% women; mean age 36.88 (SD 5.21) years.	Parents were recruited using an electronic sampling process via social media groups.
Vittrup et al (2016) [113], United States, HIC	To investigate parental media attitudes and perceptions of their children's knowledge and engagement with various media technologies and to explore their actual knowledge and experience with these tools.	Cross-sectional. Mixed method (questionnaire and interview).	101; parents; gender NR; mean age 36 (range 25 - 53) years.	Parents were recruited from childcare centers, homeschool networks, and institutions of higher education via flyers with study information and packets of surveys.

Vincent and Blot (2021) [115], France, HIC	To investigate (1) the proportion of parents who report having discussed the subject of their child's exposure to screens during a consultation with a health professional, (2) preschool children's exposure to television and mobile media devices, and (3) parents' views on the benefits and risks of exposing their children younger than 3 years of age.	Cross-sectional. Questionnaire-based.	451; parents; gender NR; median age was 34 (IQR 31 - 38) years.	Parents were recruited from 8 nurseries and a hospital's pediatric emergency room.
Wang et al (2024) [114], China, UMIC	To investigate Chinese intergenerational caregiving during the COVID-19 pandemic and different types of caregivers' beliefs, practices, and communication with children through various digital tools in the home environment.	Cross-sectional. Mixed method (questionnaire and semistructured interview).	264; parents and grandparents (185 mothers, 8 fathers, and 71 grandparents); 70% women; age NR.	Adults were recruited from preschools.

[a]Country income level was classified according to the World Bank income categories.

[b]Covers both gender and sex, depending on how this was reported in the study.

[c]UMIC: upper-middle-income country.

[d]NR: not reported.

[e]HIC: high-income country.

[f] LMIC: lower-middle-income country.

Among the 85 included studies, most were cross-sectional (74/85, 87%), 70 were based on questionnaire responses only, and 15 used a mixed methods approach of both questionnaires and interviews. The studies were conducted in a wide range of countries, but primarily in the United States (11/85, 13%), the United Kingdom (5/85, 6%), and Australia (5/85, 6%). The average number of study participants was 495 (SD 562; range 10 - 3413), of which, 82 studies only consisted of parents. In 3 studies, grandparents were also included [47,57,97]. No studies included health professionals. Accordingly, only parental perspectives are reported on in this paper. Among the 59 studies that reported participants' gender, most were women (mean 80%, SD 14%; range 47% - 100%). Participants' age was reported in 46 studies and mostly ranged between 30 and 40 years.

Characteristics and Psychometric Properties of Questionnaires Used in Included Studies

Multimedia Appendix 3 [31-146] provides the characteristics of questionnaires used among the 85 included studies. In total, 19 studies reported the title of the questionnaire, and 76 reported the item type. Among the studies describing questionnaire item type, 52 reported using questionnaires with closed-ended items, and 24 used questionnaires with a combination of closed- and open-ended items. A total of 63 studies provided information on administration format, of which most (n=42) used an online questionnaire. Information on how the questionnaire was developed was provided by 74 studies, most commonly (n=45) reported as being developed specifically for the study.

In total, 30 studies reported the total number of items in the questionnaire (mean 34; range 6 - 86), and 67 studies reported the number of items specifically related to parents' perspective of children's use of digital technologies (mean 11; range 1 - 33). Details on item scoring was reported in 61 studies, with a Likert-scale to measure level of agreement most commonly used (n=49).

Psychometric properties of questionnaires were reported by 52 studies. Among these, 14 studies conducted pilot tests to ensure face validity [33,34,47,52,55,71-73,76-78,93,100,109]. In total, 12 studies evaluated content validity by consulting experts within the field [39,44,52,53,64,65,72,73,76,86,108,110], of which, 3 studies reported content validity indexes, which ranged between 0.83 and 1.00 [44,76,108].

A total of 10 studies reported measures of construct validity based on results from a type of factor analysis [39,53,57,64,86,91,93,98,99,112]. Confirmatory factor analysis (CFA) was used in 4 studies [53,57,99,112], though the reported metrics varied. Chen and Tu [53] reported a root-mean-square error of approximation (RMSEA) of 0.06, a standardized root-mean-square residual (SRMR) of 0.05, a composite reliability of 0.88, and average variance extracted of 0.66. Dong et al [57] also performed a CFA and found that the model explained 43% of total variance, with eigenvalues ranging from 13.18 to 2.92, but no additional performance metrics were reported. Van Petegem et al [99] reported an RMSEA of 0.06 and SRMR of 0.02, while Vaiopoulou et al [112] found an

XSL•FO
RenderX

RMSEA of 0.027 and SRMR of 0.07. Exploratory factor analysis was applied in 5 studies [39,64,86,93,112]. Balaban Dağal and Bayındır [39] used principal component analysis, reporting factor loadings of 0.54 - 0.87. González-Sanmamed et al [64] found loadings between 0.52 and 0.90, while Luo et al [86] identified a 2D structure with an internal reliability of 0.95 (specific metric not reported). Nikken [93] identified a 5D structure, with item loadings >0.45, and Vaiopoulou et al [112] used principal component analysis alongside CFA, reporting factor loadings of 0.54 - 0.89. In total, 2 studies conducted a factor analysis, but did not specify which type [91,98]. Nabi and Krcmar [91] identified a 2D structure, while Ophir et al [98] reported a 2D structure explaining 69% - 70% of variance, with factor loadings ranging from 0.69 to 0.81.

Cronbach α was predominantly reported (n=26 studies) as a measure of internal consistency reliability, ranging from 0.24 to 0.95 (mean 0.80), and one study used McDonald ω as a measure of internal consistency [46], which ranged between 0.62 and 0.69. A total of 7 studies reported a measure related to assessing reliability, but did not specify which metric this was based on [77,81,86,91,100,101,109]. One study reported a test-retest reliability based on intraclass correlation (ranging between 0.64 and 0.98) [87].

Taken together, these findings show that internal consistency reliability was the most frequently reported psychometric property (n=35), whereas fewer studies reported evidence of validity, including face validity (n=14), content validity (n=12), and construct validity [10]. Few studies (n=15) reported more than a single aspect of validity and/or reliability.

Focus of Questionnaires Used in Included Studies

A total of 67 studies reported either all or some examples of the questionnaire items used to measure parents' perspectives on children's technology use (Table S1 in Multimedia Appendix 4 [31-115]). When considering which type of digital technology each questionnaire covered (ie, results of the level 1 coding), most questionnaires focused on digital media or digital devices (n=22), where technology was broadly referred to without a particular hardware, software, or content type. In total, 12 studies focused on screen time, which either covered children's exposure to any screens or to specific device types (eg, television and smartphones) [37,40,44,49,50,67,76,78,87,98,106]. Among specific device types, 9 studies focused on children's exposure to mobile touch screen devices (eg, smartphones and tablets) [32-34,55,56,70,79,97,113], and 8 studies focused on television viewing [38,42,43,62,71,94,95,111]. A total of 7 studies did not specify a particular device (eg, referring to general internet use) [35,48,53,77,102,104,105]. Gaming and computer use were referred to in 4 [36,39,75,99] and 3 [73,89,92] studies, respectively. Finally, 2 studies focused on applications [60,112].

Table 2 provides an overview of the content focus of the questionnaire items according to the 4 overall dimensions of the child-technology interaction model. When considering the overall dimensions covered, most of the 437 reported items were related to the child dimension (n=187). Within this dimension, the most common content focus of the items was parents' perspectives on the potential impact of technology on children's physical health (n=48), including sleep issues and lack of physical activity, followed by the potential influence of technology on children's emotions and behaviors (n=47) and cognition (n=12). A total of 56 items could be considered as having a content focus under the other people dimension, of which, most items aimed to measure parental regulation of children's technology use (n=32). A total of 176 items were related to the task dimension, of which, most focused on parents' perspectives on the potential impact of technology use on how children learn (n=82) and how technology can be used for social aspects (n=40). Only 14 items could be considered as related to the technology dimension, of which, safety was the most common theme (n=16).

Table . Classification of items according to the 4 dimensions of the child-technology interaction model, including codes used to classify each item.

Code[a]	Definition of code	Values (N=437), n (%)
"Child" dimension (n=187, 43%[a])		
Addiction	Item relates to child's addiction to technology.	12 (3)
Age of child	Item relates to the age of the child. Can either be mentioning a specific age (eg, 5 years) or range (eg, young children).	17 (4)
Attention	Item relates to technology's impact on children's attention.	10 (2)
Cognition	Item relates to technology's impact on children's cognition. Includes aesthetic (eg, order and beauty).	21 (5)
Creativity	Item relates to technology's impact on children's creativity.	12 (3)
Digital literacy	Item relates to children having the skills to use the technology.	8 (2)
Emotions and behaviors	Item relates to technology's impacts on children emotionally and/or their behavior (eg, makes child aggressive).	47 (9)
Physical health (including sleep issues)	Item relates to technology's impact on children's physical health.	48 (11)
Religion and culture	Item relates to technology's impact on children's religion and/or culture (eg, by helping children learn about religion or may influence cultural values).	3 (1)
Well-being	Item relates to technology's impact on children's overall well-being (eg, by influencing mental health or overall quality of life).	9 (2)
"Other people" dimension (n=56, 13%[a])		
Family interaction	Item relates to how children's technology use can promote or hinder family time or family interaction.	24 (5)
Parental regulation of technology	Item relates to regulations of technology use.	32 (7)
"Tasks" dimension (n=176, 40%[a])		
Displacement of activities	Item relates to time spent on digital technology instead of other activities such as normal or traditional play.	11 (3)
Entertainment and relaxation	Item relates to technology as being entertaining or a way of relaxation for children.	22 (5)
Keeping children occupied	Item relates to technology as being a way to "keep children occupied."	16 (4)
Learning	Item relates to children using digital technology for learning.	82 (19)
Preparing for adult life	Item relates to how technology can prepare children for adult life.	5 (1)
Social	Item relates to how technology can be used for or influences social aspects (eg, by influencing social skills or level and quality of social interactions).	40 (9)
"Technology" dimension (n=14, 4%[a])		
Internet and online	Item relates to children using the internet or being online.	2 (<1)

XSL•FO
RenderX

Code[a]	Definition of code	Values (N=437), n (%)
Safety	Item relates to whether adults feel safe about their children using technology or to the age-appropriateness of content.	16 (4)

[a]Each item was only coded as belonging to one of the listed codes.

Perspectives From Included Studies' Participants

A total of 75 studies reported the study participants' perspectives on children's use of technology. Table S1 in Multimedia Appendix 5 [31-115] provides a full summary of study findings related to perspectives toward children's technology use based on questionnaire responses. Multimedia Appendix 6 shows the distribution of reported perspectives within each of the 4 dimensions of the child-technology interaction model (ie, child, other people, tasks, and technology) according to the classification codes represented in Table 2. Please note that perspectives were coded based on reported findings in Table S1 in Multimedia Appendix 5; thus, each study could contribute to multiple themes.

Across the 4 dimensions of the child-technology interaction model, parents expressed diverse perspectives on children's use of technology.

When considering the child dimension, 23 studies reported that parents were concerned about potential negative impacts of technology on their children's physical health. Commonly raised concerns were related to lack of physical activity, sleep issues, and poor eyesight. In total, 4 studies reported that parents believed that technology could have beneficial impacts on their children's physical health, such as improvement in movement skills [45,72,82,103]. A total of 13 studies reported that parents were concerned about technology leading to addiction [31,37,47,52,59,64,65,73,83,86,97,105,109]. Parents' perspectives on the impact of technology on children's emotions and behaviors were addressed in 11 studies [40,68,72-74,82,93,102,105,113,115]. While most of these studies (n=9) reported that parents had concerns about technologies leading to behavioral issues [40,68,73,74,93,102,105,113,115], some also reported that parents believe technology could have positive impacts on children's emotions and behaviors, for example, in supporting emotional regulation [72,82,93,105].

When considering the task dimension of the child-technology interaction model, a total of 41 studies reported perspectives related to the use of and/or potential influence of technology on children's learning. Among these studies, all participants reported positive perspectives, particularly in relation to the role of technology for enhancing children's academic performance. Mixed perspectives were found for the role of technology on children's social development. In total, 9 studies reported that the participants had concerns about technology negatively impacting children's social skills and development [47,56,70,73,81,93,105,108], while 4 studies reported that the participants believed technology had a positive impact, particularly in relation to social interaction [68,72,82,105]. A total of 9 studies reported that parents acknowledged technology as a positive source of entertainment and relaxation for children [32,38,47,50,56,62,92,105,110].

For the other people dimension, parents were concerned about technology interfering with family time [37,68,73,89]. Finally, for the technology dimension, a commonly held concern among the study participants was related to children's safety when using technology, particularly in relation to children being exposed to inappropriate content [47,51,52,59,60,64,70,80].

Discussion

Principal Findings

This systematic review aimed to investigate the psychometric properties of questionnaires that have been used to measure perspectives of parents and health professionals on young children's technology use and to synthesize these perspectives. Overall, the majority of the included studies were of questionable methodological quality (n=62, 73%), particularly in terms of describing the development and validation of the questionnaires used for measuring perspectives. Of the 85 included studies, 52 studies reported psychometric properties of the questionnaire used, but the psychometric evaluation was often limited and incomplete, often focusing on a single metric for validity. When assessing the questionnaires themselves, most items focused on asking participants about how technology could aid children's learning or how it could influence their physical health, emotions and behaviors, and social skills. As none of the studies recruited health professionals, we could only provide a synthesis of parental perspectives on young children's technology use. This synthesis indicated that parents generally had positive perspectives on the use of technology for academic and educational purposes, but concerns were expressed regarding the potential negative influences of technology on children's health and well-being.

High-quality methods for capturing the perspectives of parents and health professionals on children's technology use are essential for obtaining accurate, unbiased, and reliable data. The development of a valid and reliable questionnaire is an extensive process, in which several steps are taken to ensure face, content, and construct validity as well as internal reliability [147,148]. Overall, while many studies included in this review reported some acceptable validity and reliability metrics, gaps remained in the consistent use of metrics, with only 15 studies evaluating more than 1 measure of validity and/or reliability [39,52,53,57,64,72,73,76,77,86,93,99,100,108,109]. Moreover, only 3 studies specifically aimed to develop and validate a questionnaire for measuring parents' perspectives on children's technology use [33,39,112]. Among these, the study by Balaban Dağal and Bayındır [39] conducted the most detailed validity and reliability analysis, assessing content, construct, and internal validity as well as test-retest reliability. In contrast, the study

XSL•FO
RenderX

by Al-Balushi and Al-Shihi [33] only evaluated face and content validity, and the study by Vaiopoulou et al [112] only evaluated construct and internal validity. Overall, these findings suggest that there is a need for further development of high-quality questionnaires within this research field.

When assessing the focus of questionnaire items used to measure perspectives, there was a lack of clarity and heterogeneity in the definition of technology adopted by studies. Most studies used the term "digital media" or "digital devices," which covered a range of hardware, software, and content. The lack of specificity could have influenced the responses from the study participants. For example, for the same item, some respondents may have thought of digital media as being social media, while others may have considered it to be television programs or learning apps. This could lead to inconsistent or even contradictory results and limit the accuracy and comparability of study findings. When considering the questionnaire items' focus, most items aimed to measure perspectives related to the potential impact of technology on how children learn, their physical health, emotions and behaviors, as well as social skills and interactions. It is worth noticing that the phrasing of the items themselves differed substantially both within and between studies, with some being negatively phrased (eg, "[computers] have a negative impact on children's socialisation" used in Ilgar and Karakurt [73]) and others being positively phrased (eg, "[digital media] help children communicate and interact with others" used in Ihmeideh and Alkhawaldeh [72]). This choice of item phrasing may stem from an implicit position of technological determinism, in which technology is believed to be socially causative [149]. It may be that the assumptions underlying the item development (eg, that technology use is harmful) and phrasing of the items directly influenced how participants interpreted the question and thereby how they chose to reply [150]. Specifically, negatively phrased items might have primed the respondents to focus on potential harms of technology use, whereas positively phrased items might have encouraged considerations of potential benefits. The framing of questions may also be influenced by the discipline context of the research team. As a result, the overall conclusions drawn about parental perspectives on children's technology use may be biased.

Despite the lack of construct clarity and large variability in phrasing of items, some general trends were found when synthesizing the parental perspectives reported among the included studies. In general, positive perspectives were reported in relation to how technologies can be used for enhancing children's learning, particularly in terms of academic skills and digital literacy. In contrast, concerns were often raised about technology's impact on children's physical health and emotions and behaviors. Mixed perspectives were found in relation to children's social skills. Such positive and negative perspectives on young children's use of technology have also been reported for early childhood educators [151]. Our results also concur with the findings of previous qualitative studies of parents [18-20]. The reviews by Choy et al [19], Chong et al [18], and Visier-Alfonso et al [20] reported parental concerns about technology negatively impacting their children's physical (eg, eyesight and sleep patterns), attention issues, and social development. However, Choy et al [19] also reported that parents believed that digital devices could positively contribute to children learning new skills. Taken together, the findings from previous qualitative studies and our results suggest that parents have mixed perspectives on the role of technology in their children's lives. These perceptions are likely influenced by a range of factors, including sociodemographic, cultural influences, parental age, age of their children, and parents' own experiences with technology [16]. Moreover, parental mixed perspectives may also be related to a lack of clear, evidence-based guidance on healthy technology use [17], although existing evidence does support parents' perspectives that technology use has potential risks and benefits [5].

Practical Implications

Based on our evaluation of questionnaires used for capturing the perspectives of parents on children's technology use, it is apparent that more work is required for developing high-quality questionnaires within this research field. The lack of validated questionnaires to capture the perspectives of health professionals also highlights a need. We encourage future research to prioritize the development of accurate, unbiased, and reliable questionnaires and propose that several steps are followed to support this. First, we would advise researchers to clearly define the research question, target population, their literacy level, and constructs aimed to be measured. Some of the key considerations include the type of technology, the age of children, the purpose of technology use, and the setting in which technologies are used, as these are likely to influence adults' perspectives. For example, gaming consoles could be more appropriate to ask parents of older children about who are commonly more exposed to this technology compared to younger children [3]. We would also encourage researchers to carefully consider which aspects of technology to measure, including not only the amount of time using technology (ie, quantity) but also the content and context in which it is used (ie, quality). Second, when developing the items and item response categories, we suggest using clear and concise language with balanced statements regarding potential benefits and risks associated with children's technology use to ensure that the respondents are not led toward a particular answer. Finally, we highly recommend that researchers thoroughly evaluate the validity and reliability of their questionnaire by using well-established approaches for measuring face, content, construct, and internal validity as well as assessing stability over time. Until further validated questionnaires are developed, we recommend the use of existing questionnaires with substantive validity evidence, such as the Balaban Dağal and Bayındır [39] questionnaire, if it matches the study's research question.

Our synthesis of perspectives revealed that parents have mixed views on the role of technology in their children's lives. While the potential benefits of technology, particularly for enhancing academic skills and social interactions, were acknowledged, concerns were often expressed about potential negative impacts on children's physical and mental health and overall development. These findings suggest that parents are cognizant of the complex role of technology in young children's lives, and this aligns with prior reports that parents are struggling to navigate conflicting narratives surrounding children's

XSL•FO
RenderX

technology use [17]. These findings highlight several priorities for future research. Specifically, parents may be exposed to a broad range and, at times, controversial guidance from educators, health professionals, and media sources, making it challenging to make decisions regarding healthy technology use. We encourage future research to investigate the basis for parent perspectives, including what influences their perspectives. Moreover, prior research has reported sources parents use to gain information about health issues [16], but whether parents have the ability to independently develop a clear understanding of the evidence regarding the likely impacts of technology use on child outcomes is not known. Thus, this presents an important area for further investigation. Future research should also investigate the impact of social desirability on parental perspectives. Further, more work is required to understand whether perspectives are evidence-based or reflect parental views on ideal childhoods and other values. Addressing these research gaps would enable educators and health professionals to better support parents through the challenges of raising children in a digital world by providing a better understanding of how parents' perspectives are developed and how these relate to their decision-making regarding their children's use of technology.

Strengths and Limitations

Strengths of this systematic review included the developed search strategy applied in a wide range of databases as well as the cross-checking of study screening, quality assessment, and data extraction independently by 2 authors (CLR and IPHA). The development of a comprehensive, theory-based, 2-level coding framework for classifying the focus of the questionnaires and the items used was another strength. This framework, based on the child-technology interaction model [14], enabled a structured and systematic approach for assessing the diverse ways in which studies measured parental perspectives. Although we acknowledge that some codes could be classified under multiple dimensions of the child-technology interaction model, the application of this structured framework enhances the reproducibility of our findings and provides an early foundation for future research seeking to improve the measurement of perspectives on children's technology use.

Only reports published in English were considered for inclusion, and potentially relevant studies might have been missed due to unclear titles or abstracts and artificial intelligence–supported screening. Moreover, we aimed to report how perspectives on children's technology use may depend on the population group (eg, parents and health professionals) and the age of the child. However, these assessments were not feasible, as the only participants in the included studies were parents, and the age of the children was rarely specified.

Conclusions

This systematic review found that parents' perspectives on children's technology use have been assessed using questionnaires in several studies. However, the reported psychometric evaluation of the questionnaires was limited and incomplete, with most studies focusing on a single metric. Further, varied definitions of technologies make it difficult to establish to what extent the existing literature is examining variations in technologies relative to parents' perspectives. Study participants consisted of parents only, highlighting a clear evidence gap in understanding health professionals' perspectives on children's technology use. The reported parental perspectives were mixed. While positive views were found, considering the use of technology for enhancing children's learning and skill development, concerns were commonly raised about potential negative impacts on children's physical health and emotions and behaviors. As parents' perspectives may influence their children's use of technology and potentially associated development, there is a need for better-quality tools to measure adults' perspectives, understand how perspectives are developed, and how they influence practice. We encourage such work to focus on improving questionnaire design based on a clear theoretical understanding of technologies to prevent confusion in defining terms and item phrasing.

Funding

This research was funded by the Australian Research Council Centre of Excellence for the Digital Child (CE200100022).

Data Availability

Data sharing is not applicable to this paper as no new data were created or analyzed in this study.

Authors' Contributions

All authors have substantially contributed to the study. CLR, DH, JZ, and LS were involved with conception. All authors were involved in the design of the review. CLR and IPHA conducted the searches, study selection, and data extraction. CLR, DH, and JZ developed the coding framework. CLR drafted the manuscript and performed revisions. All authors provided substantial feedback and edited and approved the final manuscript.

Conflicts of Interest

None declared.

Abstract

Background: Preoperative anxiety affects an estimated 50% to 70% of children undergoing surgery and is associated with poorer perioperative cooperation, increased postoperative distress, and delayed recovery. Digital storytelling and immersive technologies, including virtual reality and augmented reality, have emerged as child-centered preparation tools to improve the preoperative experience.

Objective: This systematic review and meta-analysis aimed to synthesize and critically appraise the available evidence on the effects of these interventions in reducing preoperative anxiety among pediatric patients undergoing elective surgery.

Methods: A systematic search was conducted in PubMed, Scopus, Web of Science, and the Cochrane Library for studies published between January 2015 and June 2025. Randomized controlled trials and quasi-experimental studies evaluating digital storytelling (eg, narrative-based apps or videos) or immersive technologies (eg, virtual reality or augmented reality) were included. Preoperative anxiety was assessed using validated measures such as the Modified Yale Preoperative Anxiety Scale, State-Trait Anxiety Inventory, or Visual Analog Scale. Further, 2 reviewers independently screened studies and extracted data. Risk of bias was assessed using the Cochrane Risk of Bias tool version 2. A random-effects meta-analysis was performed in R using standardized mean differences.

Results: A total of 379 records were identified, and 13 studies met the inclusion criteria. Most studies reported lower preoperative anxiety in intervention groups compared with standard care or conventional preparation. Further, 9 studies provided sufficient comparable data for meta-analysis, showing a significant pooled reduction in anxiety favoring digital interventions (standardized mean difference=−0.67, 95% CI −0.93 to −0.41), with substantial heterogeneity (I^2=79.3%, P<.001). Overall risk of bias was high in most trials, primarily due to deviations from intended interventions and limitations in blinding.

Conclusions: This review suggests a trend toward reduced preoperative anxiety among pediatric patients receiving digital storytelling and immersive technology–based interventions. However, the certainty of evidence is limited by substantial heterogeneity, the small number of studies included in the meta-analysis, variability in outcome measures, and overall study quality. Therefore, the pooled estimate should be interpreted with caution. Further high-quality studies using standardized outcomes and robust methodology are needed, including evaluation of parental anxiety and longer-term postoperative effects.

KEYWORDS

preoperative anxiety; children; virtual reality; immersive technology; digital storytelling

Introduction

Preoperative anxiety is a common and often expected emotional response among children facing surgery, and it can arise at any point before the procedure [1]. It affects an estimated 50% to 70% of pediatric patients and represents a major concern in pediatric anesthesia and perioperative care [2]. High levels of anxiety can negatively influence cooperation with medical staff and increase perioperative distress. From a physiological perspective, heightened anxiety activates the stress response system, including increased sympathetic nervous system activity and hypothalamic-pituitary-adrenal axis activation, which may contribute to elevated heart rate, cortisol release, and heightened pain perception. These responses have been associated with greater postoperative pain and increased risk of emergence delirium [3,4].

From a psychological and behavioral perspective, anxiety may impair coping ability, increase anticipatory fear, and reduce a child's capacity to engage with medical procedures, which can lead to poorer perioperative cooperation and increased distress during anesthesia induction. In addition, negative perioperative experiences may reinforce maladaptive fear responses and contribute to postoperative behavioral changes, such as sleep disturbances, separation anxiety, or regression, which may persist beyond hospitalization [3,4]. These interconnected physiological and psychological pathways highlight the clinical importance of identifying effective and developmentally appropriate approaches to reduce anxiety before surgery.

Traditional strategies for reducing pediatric preoperative anxiety include pharmacological approaches (eg, benzodiazepine premedication) as well as nonpharmacological interventions such as preoperative education, hospital tours, behavioral preparation programs, child life specialist support, role-play, and distraction techniques [2,5]. Although these approaches can be beneficial, many require additional staffing and time, may not be consistently available across institutions, and can be challenging to implement in busy or resource-limited settings [6]. As a result, there is ongoing interest in scalable, engaging, and noninvasive preparation methods that can be delivered efficiently and tailored to children's developmental needs.

In recent years, digital storytelling and immersive technologies have emerged as promising alternatives for pediatric preoperative preparation. In this review, digital storytelling refers to narrative-based preparation delivered through mobile or tablet apps, interactive stories, animated educational content, or video-based formats that explain the surgical journey in a child-friendly manner [7]. In contrast, immersive technologies include platforms such as virtual reality (VR) and augmented reality (AR) that provide interactive and immersive simulated environments, often through head-mounted displays or AR-enabled devices. These interventions may reduce anxiety through several complementary mechanisms, including attentional distraction, increased engagement, improved procedural understanding, and enhanced coping through familiarization with the hospital environment [8].

Previous systematic reviews and meta-analyses have reported beneficial effects of VR-based interventions on anxiety and related perioperative outcomes in pediatric settings; however, these reviews often focus predominantly on VR and may not fully capture newer narrative-based digital storytelling tools or more recent immersive applications [9,10].

Despite increasing research interest, the available evidence remains heterogeneous in intervention type, delivery mode, timing of exposure, surgical populations, and anxiety measurement tools. In addition, the overall certainty of evidence is influenced by variability in study quality and reporting. Therefore, this systematic review and meta-analysis aimed to synthesize and critically appraise the available evidence on the effects of digital storytelling and immersive technology–based interventions (including VR, AR, and app-based storytelling tools) in reducing preoperative anxiety among pediatric patients undergoing elective surgery, compared with standard care or conventional preparation methods.

Methods

Study Design

This study was a systematic review and meta-analysis designed to synthesize and critically appraise the available evidence on the effects of digital storytelling and immersive technology–based interventions on preoperative anxiety in pediatric patients undergoing elective surgery. The review was structured according to the PICOS (Population, Intervention, Comparison, Outcomes, and Study) framework: the population comprised pediatric patients (≤18 years) undergoing elective surgical procedures; the interventions included digital storytelling and immersive technologies such as mobile or tablet-based apps, VR, AR, and related digital preparation tools; comparators consisted of standard care or conventional preoperative preparation methods (eg, routine verbal or written information); outcomes focused on quantitatively measured preoperative anxiety using validated instruments; and eligible study designs included randomized controlled trials (RCTs) and quasi-experimental comparative studies. The review was conducted in accordance with the *Cochrane Handbook for Systematic Reviews of Interventions* and reported following the PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) 2020 guidelines [11,12]. The review protocol was prospectively registered in PROSPERO (CRD420251111293).

Search Strategy

A comprehensive electronic search was performed in 4 databases: PubMed, Scopus, Web of Science, and the Cochrane Library. Searches were developed using a combination of free-text keywords related to the population (child, pediatric, or pediatric), the outcome (preoperative anxiety, surgical anxiety, or procedure-related anxiety), and the intervention

XSL•FO
RenderX

(digital storytelling, interactive story, animated book, VR, AR, mobile or tablet apps, and video-based education).

These concepts were combined using Boolean operators (AND/OR) and adapted to the syntax and indexing requirements of each database. The search was restricted to studies published between January 2015 and June 2025. The PROSPERO registration (CRD420251111293) reflects the initial planned search period up to January 2025; however, an updated search was conducted in June 2025 before final analysis to ensure inclusion of the most recent evidence. The search was limited to English-language publications where applicable. In addition, the reference lists of included studies and relevant reviews were manually screened to identify any additional eligible papers. The complete database-specific search strategies are provided in Multimedia Appendix 1.

Eligibility Criteria

Studies were eligible for inclusion if they met the following criteria:

- Population: pediatric participants undergoing elective surgical procedures. Although the review focus was children, studies were included if the participants were predominantly pediatric (≤18 years) or if pediatric data were extractable.
- Intervention: any digital or immersive preoperative preparation intervention delivered to the child, including (1) immersive technologies, such as VR, AR, or mixed reality (MR), and/or (2) digital storytelling interventions, such as narrative-based educational content delivered through mobile or tablet apps, interactive story formats, or video-based preparation tools. Studies in which the intervention combined digital and nondigital components (eg, verbal instruction plus a VR tool) were eligible only when the digital or immersive component was the primary active element intended to reduce anxiety.
- Comparator: standard care or conventional preparation methods, including routine verbal information, written materials, or usual preoperative practice.
- Outcomes: studies were required to report quantitative preoperative anxiety outcomes assessed using validated instruments such as the Modified Yale Preoperative Anxiety Scale (mYPAS), State-Trait Anxiety Inventory (STAI), Visual Analog Scale (VAS), or comparable validated measures.
- Study design: RCTs and quasi-experimental comparative studies.
- Publication characteristics: studies published in English with available full text.

Studies were excluded if they (1) included adult-only samples without extractable pediatric results; (2) did not report quantitative preoperative anxiety outcomes; or (3) used noncomparative publication formats, such as reviews, editorials, conference abstracts, protocols, or case reports.

Definition of Digital Storytelling and Immersive Technology Interventions

For this review, digital or immersive interventions were defined as preoperative preparation tools delivered through digital media or immersive platforms with the goal of reducing anxiety by improving engagement, familiarization, distraction, or coping before surgery.

Digital storytelling interventions were defined as narrative-based educational content delivered via digital devices (eg, smartphones, tablets, computers, or hospital screens). These interventions included story-driven or character-guided formats such as interactive stories, animated storybooks, app-based storytelling programs, or video-based educational storytelling designed to explain the surgical journey in a developmentally appropriate manner [13].

Immersive technology interventions were defined as interventions using immersive or interactive environments, including VR, AR, or MR, typically delivered through a head-mounted display or interactive AR-enabled devices. These interventions commonly provided simulated exposure to perioperative environments (eg, operating room tours) or interactive distraction content aimed at reducing anticipatory distress [7].

Some interventions combined digital components with conventional nondigital elements (eg, routine verbal explanations alongside a digital tool). In such cases, studies were considered eligible when the digital or immersive component represented the primary active element of the intervention, was delivered directly to the child preoperatively, and the study design allowed comparison with a control group receiving standard care or conventional preparation alone.

Study Selection and Screening

All search results were imported into Rayyan for initial screening and duplicate removal [14]. A total of 2 reviewers independently screened titles and abstracts for relevance. Full-text reviews were conducted for all studies that met the inclusion criteria or were deemed potentially eligible. Disagreements at any stage were resolved through discussion or by consulting a third reviewer to reach a consensus. Interrater agreement between the 2 reviewers during title and abstract screening was high (Cohen κ=0.82). Agreement at the full-text screening stage was also high (κ=0.86). Discrepancies were resolved through discussion or consultation with a third reviewer.

Quality Assessment

The risk of bias of included RCTs was assessed using the Cochrane Risk of Bias tool version 2 (RoB 2) [15]. RoB 2 evaluates potential bias across five domains: (D1) bias arising from the randomization process, (D2) bias due to deviations from intended interventions, (D3) bias due to missing outcome data, (D4) bias in measurement of the outcome, and (D5) bias in selection of the reported result. Each domain was rated as low risk of bias, some concerns, or high risk of bias, and an overall risk-of-bias judgment was assigned for each study based on the RoB 2 algorithm. Further, 2 reviewers independently conducted the assessments, and disagreements were resolved through discussion; when consensus could not be achieved, a third reviewer was consulted. This approach provided a structured and transparent evaluation of the internal validity of the included trials. Agreement between reviewers for risk-of-bias

XSL•FO
RenderX

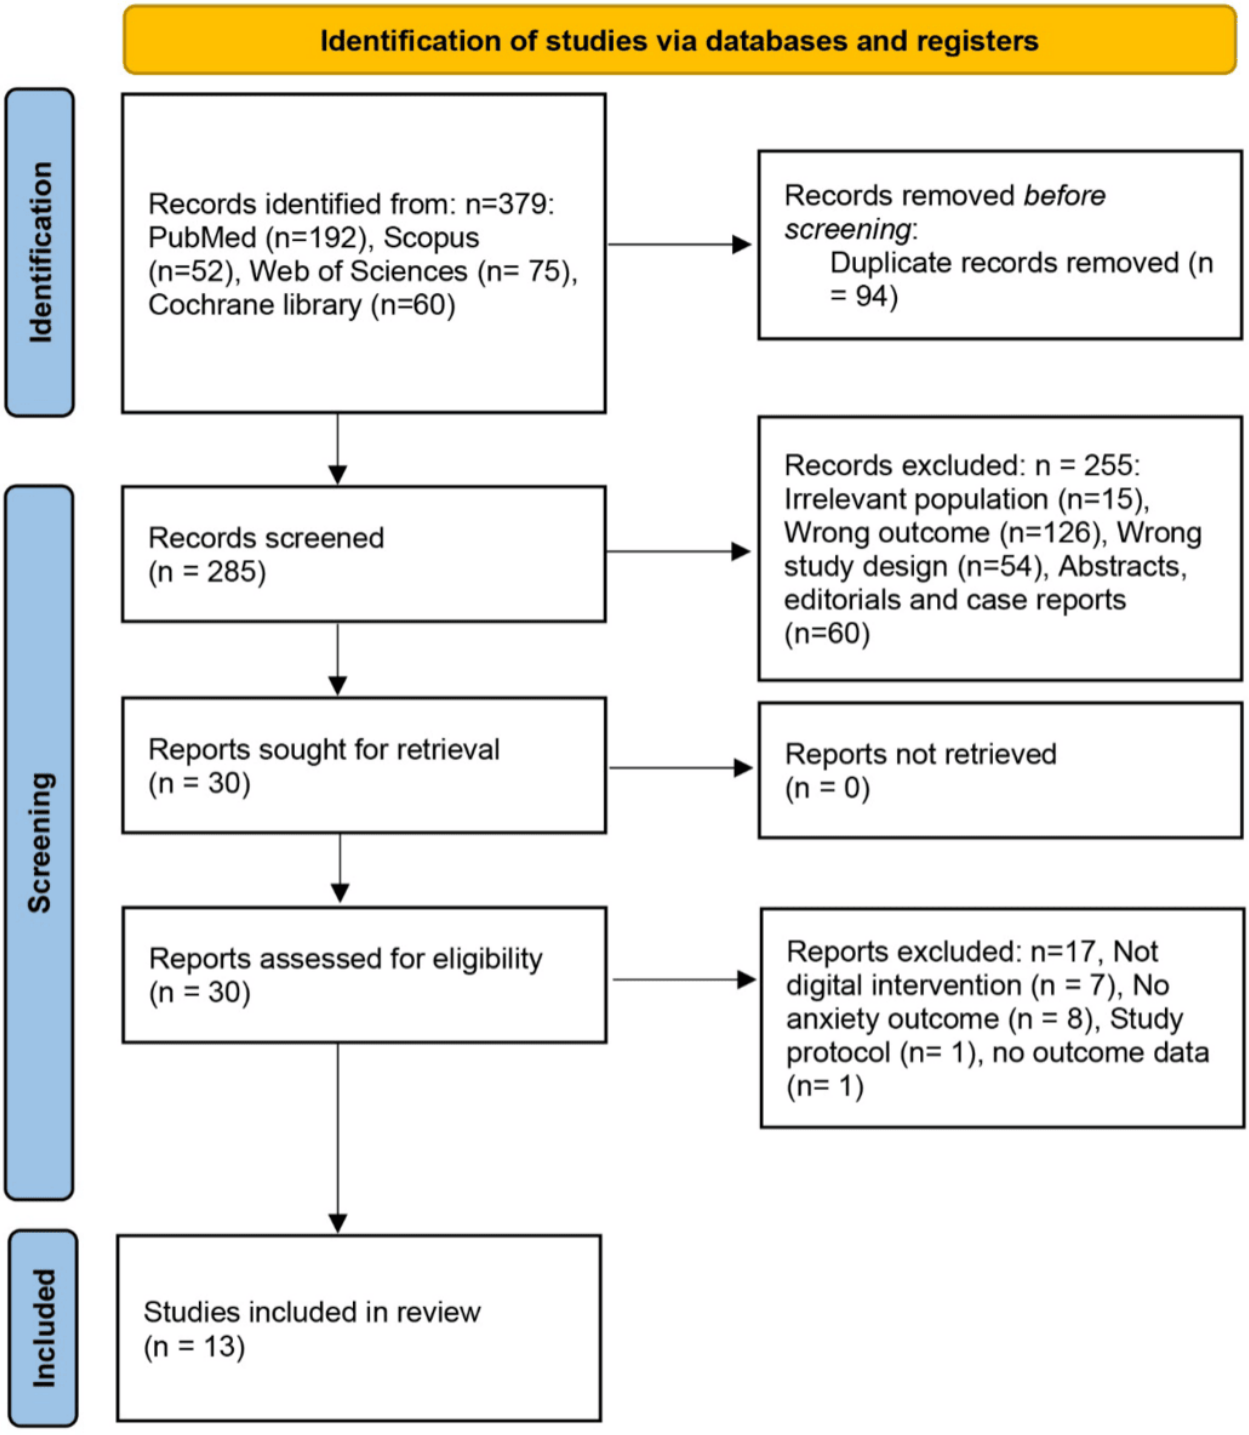
assessment was high (κ=0.84), with disagreements resolved through consensus.

Data Extraction and Management

A standardized data extraction form was developed and pilot-tested for consistency. Further, 4 reviewers independently extracted data on study characteristics (authors, year, and country), sample size, participant age and gender, type of surgery, intervention type and duration, control condition, anxiety measurement tools, outcome data (mean scores, SDs, and *P* values), and parental anxiety or treatment adherence if reported. Extracted data were cross-checked and managed using Microsoft Excel (Microsoft Corp). Any discrepancies were resolved through group discussion. Interrater agreement for data extraction was high (κ=0.88), indicating strong consistency between reviewers. The standardized data extraction form used in this review was developed and pilot-tested for consistency. The full extraction template, including variable definitions, is provided in Multimedia Appendix 2 to enhance transparency and reproducibility.

Statistical Analysis

All statistical analyses were conducted using R (R Foundation; version 4.3) with the *meta* and *metafor* packages. A random-effects meta-analysis model was used to account for expected clinical and methodological heterogeneity among the included studies. Studies were included in the meta-analysis only if they provided sufficient quantitative data to calculate standardized mean differences (SMDs; ie, means and SDs or equivalent statistics) at comparable preoperative time points, and used outcome measures considered sufficiently similar for pooling. Given the use of multiple validated anxiety measurement instruments across studies, effect sizes were standardized using SMDs with 95% CIs. While this approach allows pooling across different scales, it assumes that these instruments capture sufficiently comparable constructs of preoperative anxiety despite differences in measurement approach and underlying dimensions (Multimedia Appendix 3). Statistical heterogeneity was assessed using the I^2 statistic and the Cochran Q test. An I^2 value greater than 50% or a *P* value less than .10 from the Q test was considered indicative of substantial heterogeneity. Subgroup or sensitivity analyses were considered but ultimately not performed due to the small number of studies included in the meta-analysis (n=5). Conducting such analyses with a limited number of studies would result in low statistical power and a high risk of producing unstable or spurious findings. Therefore, these analyses were deemed methodologically inappropriate in this context. Publication bias assessment (eg, funnel plot or Egger test) was not performed because fewer than 10 studies were included in the pooled meta-analysis, limiting interpretability and statistical power [16]. All analyses were conducted with a significance level set at $P<.05$.



Results

Study Selection

A total of 379 records were initially identified through database searches: PubMed (n=192), Scopus (n=52), Web of Science (n=75), and the Cochrane Library (n=60; Figure 1). After removing 94 duplicates, 285 unique records were screened by title and abstract. During this stage, 255 records were excluded due to irrelevant population (n=15); wrong outcome (n=126); inappropriate study design (n=54); or publication type such as abstracts, editorials, or case reports (n=60). A total of 30 full-text papers were assessed for eligibility. Of these, 17 studies were excluded, including studies evaluating nondigital interventions (n=7), studies not reporting anxiety outcomes (n=8), and 2 additional publications that were not eligible for synthesis (a protocol and a secondary evidence synthesis). Ultimately, 13 studies met the inclusion criteria and were included in the final systematic review.

Characteristics of Included Studies

The 13 included studies were published between 2017 and 2025 and were conducted across multiple countries, including South Korea, Canada, Iran, the Netherlands, Turkey, China, Finland, and Spain (Table 1). Most studies were RCTs, with sample sizes ranging from 40 to 241 participants. The included studies primarily involved pediatric surgical populations, with some variability in reported age ranges, representing a potential source of clinical heterogeneity. The proportion of male participants varied across trials, including 1 study enrolling male-only participants (circumcision surgery). The types of surgery included general pediatric, ENT (ear, nose, and throat), ophthalmic, orthopedic, dental, abdominal, and circumcision procedures and were largely elective.

Intervention Characteristics

Digital interventions varied in type and delivery mode across the included studies (Table 2). VR interventions were the most frequently evaluated modality and were typically delivered using head-mounted devices such as Samsung Gear VR, HTC Vive, Meta Quest 2, or NOLO VR systems. AR and MR approaches were less commonly studied and were delivered through AR-enabled devices, including platforms such as Microsoft HoloLens (Microsoft Corp). A smaller number of studies evaluated mobile or tablet-based apps, including digital storytelling interventions and video-based educational preparation tools.

XSL•FO
RenderX

Table 2. Intervention characteristics and control conditions. Narrative content indicates whether the digital intervention included a story-based structure, character guidance, or procedural walkthrough. Delivery platforms range from immersive headsets to mobile or tablet apps. Duration and timing reflect when and for how long the intervention was used relative to the surgery. Interventions marked as "not reported" were either not stated or unclear in the original studies.

Study	Digital tool type	Delivery mode and platform	Narrative content	Control condition	Timing	Duration (min)
Ryu et al, 2017 [17]	VR[a] tour	Gear VR headset)Samsung)	Pororo cartoon guide	Verbal info	1 h preoperative	4
Chow et al, 2017 [18]	STM[b] tablet app	Android tablet	Story-led 3D cartoon	Usual care	Home and preoperative day	20

Pan et al, 2025 [29]	Mobile app video	Smartphone QR code	Hospital staff explain the process	No app	1 d preoperative	11

[a]VR: virtual reality.

[b]STM: story-telling medicine.

[c]AR: augmented reality.

[d]OR: operating room.

Narrative elements, such as animated characters, guided procedural walkthroughs, and story-based visuals, were incorporated into many of the interventions, whereas a subset focused primarily on distraction without structured storytelling content. Control conditions generally consisted of standard preoperative care, including routine verbal and/or written information, usual education, or nonnarrative digital content. The timing and duration of interventions varied, ranging from immediate preoperative exposure to delivery up to 2 weeks before surgery, with most interventions lasting approximately 4 to 20 minutes.

Effectiveness of Digital Interventions

Anxiety outcomes were assessed using a range of validated instruments, including observer-rated measures (eg, mYPAS or Modified Yale Preoperative Anxiety Scale Short Form, or Yale Preoperative Anxiety Scale) and self-report tools (eg, STAI, VAS, or Children's Perioperative Multidimensional Anxiety Scale), across multiple perioperative time points. Table 3 provides a detailed summary of outcome measures, assessment timing, and between-group effects for each included study, along with reported findings on parental anxiety and intervention feasibility.

Across studies, most interventions were associated with lower levels of preoperative anxiety compared with control conditions, although the magnitude and statistical significance of these effects varied.

XSL•FO
RenderX

Table 3. Impact of digital interventions on preoperative anxiety, parental stress, and treatment compliance. "Reduced anxiety" indicates lower anxiety scores in the intervention group compared with the control group. "No significant between-group difference" indicates statistical nonsignificance between intervention and control at reported time points. Time points (T0-T6) are reported as defined in the original studies.

Study	Anxiety measures	Assessment time points	Effect on child preoperative anxiety (between-group comparison)	Parental anxiety	Feasibility or adherence
Ryu et al, 2017 [17]	mYPAS[a]; PBRS[b]; ICC[c]	30 min post	Significant reduction in anxiety in VR[d] group (P<.001)	Not reported	Improved induction compliance (↑ ICC) and behavior (↓ PBRS)
Chow et al, 2017 [18]	CPMAS[e]	T1-T3	Significant reduction in anxiety in digital storytelling group (large effect size; Cohen d=0.96)	Not reported	90% completed the intervention
Park et al, 2019 [19]	mYPAS; NRS[f]	Baseline; induction	Significant reduction in anxiety in the mirrored VR group (P=.025)	Significant reduction in parental anxiety (NRS; P=.009)	Comparable adherence reported
Ryu et al, 2019 [20]	mYPAS	Baseline; preinduction	Significant reduction in anxiety in the VR group (P<.05)	Not reported	Not reported
Dehghan et al, 2019 [21]	YPAS[g]	Pre or post	Significant reduction in anxiety in the VR group (P<.05)	Not reported	Not reported
Eijlers et al, 2019 [22]	mYPAS; VAS[h]	T1-T5	No significant between-group difference	No significant between-group difference (STAI-S[i])	22% removed VR headset
Buyuk et al, 2021 [23]	CAM-S[j]	Pre or post	Significant reduction in anxiety in the VR group (P<.001)	Not reported	100% completed intervention
Wu et al, 2022 [24]	mYPAS-SF[k]	T1-T5	Significant reduction in anxiety in VR group at specific time points (eg, T3; P=9 × 10)	No significant between-group difference (STAI[l])	Improved induction compliance (↑ ICC; P=.003)
Chamberland et al, 2024 [25]	mYPAS-SF	Admission; induction	Significant reduction in anxiety in the AR[m] group compared with the control	Not reported	Dropouts reported (n=19 in AR group)
Lee et al, 2023 [26]	mYPAS	Baseline; preinduction	Significant reduction in anxiety in VR compared with tablet video (P=.02)	Not reported	Better induction compliance in VR (ICC; P=.007)
Kerimaa et al, 2023 [27]	VAS; STAI-S; FAS[n]	T1-T4	No significant between-group difference	No significant between-group difference	100% completed intervention
Carbó et al, 2024 [28]	mYPAS/m YPAS-SF	T0-T2	Significant reduction in anxiety in the VR education group (P<.001)	No significant between-group difference (STAI-S)	100% completed intervention
Pan et al, 2025 [29]	mYPAS-SF; VAS	T0-T4	Significant reduction in anxiety in the mobile-based intervention group (P=.012)	Significant reduction in parental anxiety (VAS; P=.013)	100% completed intervention

To provide a more systematic overview of findings, a structured narrative synthesis was conducted to assess the direction and consistency of intervention effects across all included studies (Table 4). Direction of effect was categorized as reduction in anxiety, no difference, or unclear, and statistical significance was determined based on between-group comparisons. As shown in Table 4, most studies (11 of 13) reported reductions in preoperative anxiety in the intervention groups compared with standard care or control conditions, with most demonstrating statistically significant between-group differences.

Table 4. Summary of direction and statistical significance of intervention effects across included studies.

Study	Intervention type	Anxiety outcome	Direction of effect	Statistical significance
Ryu et al, 2017 [17]	VR[a]	mYPAS[b]	↓ Anxiety	Significant
Chow et al, 2017 [18]	Digital storytelling	CPMAS[c]	↓ Anxiety	Significant
Park et al, 2019 [19]	VR + parental mirroring	mYPAS	↓ Anxiety	Significant
Ryu et al, 2019 [20]	VR	mYPAS	↓ Anxiety	Significant
Dehghan et al, 2019 [21]	VR	YPAS[d]	↓ Anxiety	Significant
Eijlers et al, 2019 [22]	VR	mYPAS, VAS[e]	No clear difference	Not significant
Buyuk et al, 2021 [23]	VR	CAM-S[f]	↓ Anxiety	Significant
Wu et al, 2022 [24]	VR	mYPAS-SF[g]	↓ Anxiety	Significant
Chamberland et al, 2024 [25]	AR[h]	mYPAS-SF	↓ Anxiety	Significant
Lee et al, 2023 [26]	VR vs tablet	mYPAS	↓ Anxiety	Significant

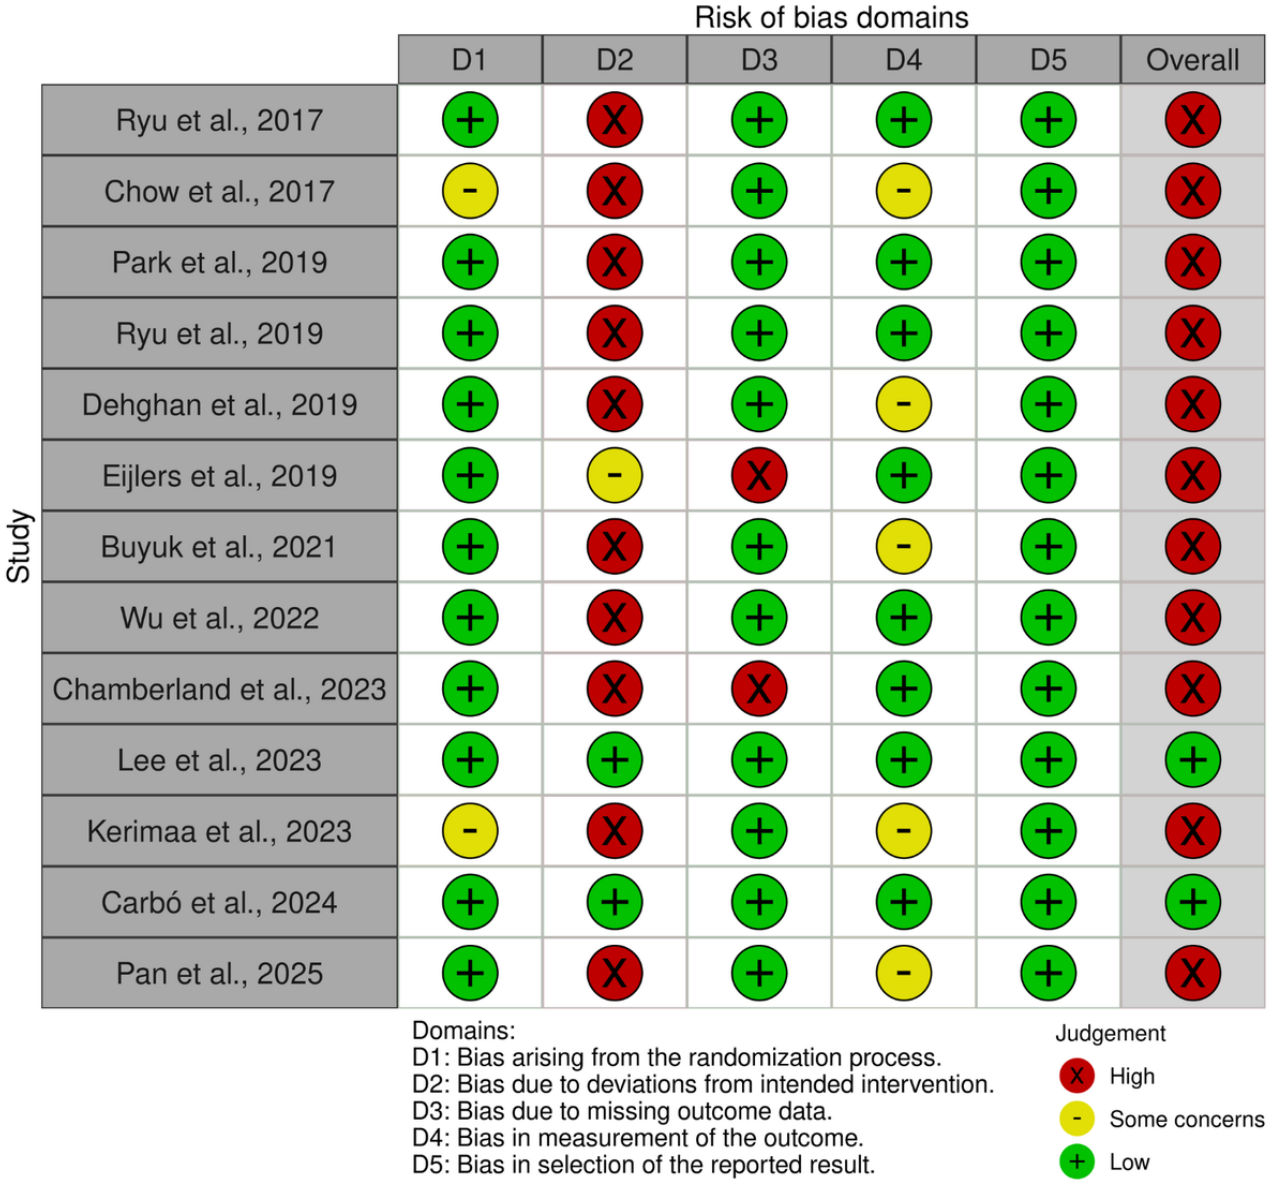
A total of 2 studies (Eijlers et al [22]; Kerimaa et al [27]) did not report statistically significant between-group differences, although both observed reductions in anxiety over time within groups. Overall, these findings indicate a generally consistent direction of effect favoring digital interventions, with variability in effect size and statistical significance likely reflecting differences in intervention type, timing of delivery, population characteristics, and outcome measurement tools. This structured synthesis complements the meta-analysis by highlighting patterns of consistency despite substantial heterogeneity.

Meta-Analysis Findings

Figure 2 [17,19,20,22-26,28] presents the results of the random-effects meta-analysis evaluating the effects of digital interventions on preoperative anxiety in pediatric patients undergoing elective surgery. Nine studies comprising 508 participants in the intervention groups and 533 participants in the control groups were included. Most studies demonstrated lower anxiety scores in children receiving digital interventions, with SMDs ranging from −1.12 to 0.08. The pooled analysis showed a statistically significant reduction in preoperative anxiety favoring digital interventions compared with standard care or conventional preparation methods (SMD=−0.67, 95% CI −0.93 to −0.41). However, substantial heterogeneity was observed across studies (I^2=79.3%, P<.001), indicating considerable variability in effect sizes. Given this heterogeneity and the diversity of intervention types, populations, and outcome measures, the pooled estimate should be interpreted with caution. Nevertheless, the overall direction of effect across studies generally favored digital interventions for reducing preoperative anxiety.

XSL•FO
RenderX

Figure 2. Forest plot showing the effectiveness of digital storytelling and immersive technologies in reducing preoperative anxiety among children.



Risk of Bias Assessment

Risk of bias assessments using RoB 2 are summarized in Figure 3 [17-29]. For bias arising from the randomization process (D1), most studies were judged to be at low risk, while a minority raised some concerns due to limited reporting of allocation procedures. Bias due to deviations from intended interventions (D2) was the most frequent limitation, as blinding of participants and personnel was generally not feasible for interactive interventions (eg, VR or AR or app-based tools), potentially influencing engagement and subjective anxiety reporting.

XSL•FO
RenderX

Figure 3. Risk of bias assessment of included studies.

Most studies were judged at low risk for missing outcome data (D3), although a small number had high risk or some concerns due to attrition or incomplete reporting. Bias in measurement of the outcome (D4) and selection of the reported result (D5) was generally low, with some concerns in studies with insufficient reporting detail. Overall, 2 studies were judged as low risk of bias (Carbó et al [28]; Lee et al [26]), 1 study had some concerns, and the remaining trials were judged as high risk of bias, largely driven by D2 (deviations from intended interventions).

Discussion

Principal Findings

This systematic review and meta-analysis synthesized the available evidence on the effectiveness of digital storytelling and immersive technology for reducing preoperative anxiety in children.

The findings suggest that digital storytelling and immersive technologies may reduce preoperative anxiety in children, although interpretation should remain cautious given heterogeneity and the overall risk of bias across included trials. These results align with a growing body of literature advocating for nonpharmacological, child-centered approaches to improve the perioperative experience.

The significant anxiety reduction observed in our analysis (SMD=–0.99) strongly supports the efficacy of digital interventions and can be understood through 2 primary psychological mechanisms: cognitive distraction and cognitive remodeling. These findings are consistent with a robust and growing body of evidence demonstrating the power of technology to positively shape the pediatric perioperative

XSL•FO
RenderX

experience [30,31], the substantial heterogeneity observed (I^2=78.1%), and the small number of studies included in the meta-analysis limit the interpretability and clinical applicability of the pooled estimate.

This heterogeneity likely reflects multiple sources of variability across studies. First, interventions differed in modality and underlying mechanisms, including immersive technologies (eg, VR and AR) and narrative-based digital storytelling applications, which may influence anxiety through distinct pathways such as distraction, familiarization, or cognitive restructuring. Second, there was variation in the timing and duration of intervention delivery, ranging from immediate preoperative exposure to preparation delivered several days before surgery. Third, differences in clinical populations, including age ranges, types of surgical procedures, and perioperative contexts, may have influenced baseline anxiety levels and responsiveness to intervention. Finally, variability in outcome measurement, particularly the use of both observer-rated tools (eg, mYPAS) and self-report instruments (eg, STAI and VAS), may contribute to differences in effect size estimation, as these instruments capture different dimensions of anxiety.

Given these sources of heterogeneity and the limited number of studies available for quantitative synthesis, the pooled effect estimate should be interpreted as an approximate indication of overall effect direction rather than a precise or generalizable measure of intervention efficacy.

Only 5 studies provided sufficiently comparable outcome data for meta-analysis, which further limits the robustness of the pooled estimate. The remaining studies were synthesized narratively and generally demonstrated reductions in anxiety, although differences in reporting formats and assessment time points restricted quantitative integration. Accordingly, greater emphasis should be placed on the consistency and direction of findings across individual studies rather than the pooled estimate alone.

While the included studies did not directly assess underlying psychological or neurophysiological mechanisms, several theoretical frameworks may help explain the observed reductions in preoperative anxiety. One possible explanation, particularly for immersive technologies such as VR, is cognitive distraction. Grounded in the limited capacity model of attention, this principle suggests that the brain has finite resources to process simultaneous stimuli [10]. By immersing a child in a compelling, interactive, and sensorially rich virtual environment, these interventions may engage attentional resources, thereby reducing the capacity available to process anxiogenic cues from the clinical setting, such as unfamiliar equipment or procedural environments [32].

Evidence from prior research outside the included trials suggests that immersive environments may influence neural processing related to pain and emotional distress, including activity in regions such as the thalamus, insula, and anterior cingulate cortex [33]. In addition, the sense of “presence”—the subjective feeling of being immersed in a virtual environment—may further enhance attentional engagement and contribute to distraction effects [34]. Similarly, cognitive-behavioral frameworks support the role of gradual exposure and improved understanding in reducing anxiety responses. However, it is important to emphasize that these mechanisms were not directly measured in the included studies, which primarily assessed anxiety using behavioral or self-report instruments. Therefore, these explanations should be interpreted as theoretical rather than empirically established within this review. Additionally, different intervention types (eg, VR, AR, and narrative-based digital applications) are likely to operate through distinct mechanisms, and applying a single explanatory framework across all modalities may oversimplify their effects.

Our findings are consistent with existing systematic reviews and meta-analyses showing that immersive digital interventions, particularly VR, can reduce perioperative anxiety in pediatric populations. For example, Chen et al [30] conducted a systematic review and meta-analysis of randomized trials and reported that VR-based preoperative preparation reduced anxiety and improved induction compliance in children. Similarly, Eijlers et al [31] synthesized pediatric evidence across medical procedures and concluded that VR is an effective nonpharmacological intervention for reducing anxiety and pain in children. Other meta-analyses focused on surgical contexts have also reported beneficial effects of preoperative VR on anxiety, supporting the direction of effect observed in the present review [35]. In addition, more recent reviews have highlighted the growing interest in immersive perioperative tools, including VR and emerging AR platforms, although the evidence base remains heterogeneous and varies in methodological quality [8]. Taken together, our findings reinforce prior evidence supporting VR-based preparation, while extending the literature by incorporating newer formats such as digital storytelling and app-based interventions alongside immersive technologies.

Beyond distraction, several interventions, particularly those providing guided procedural walkthroughs or narrative-based preparation (eg, Wu et al [24]), may promote cognitive restructuring through procedural familiarization and skills rehearsal [24]. These tools function as a form of digital exposure therapy or guided preparation, allowing children to “rehearse” the surgical journey in a safe and engaging format [8]. By following a relatable animated character or interacting with a virtual model of the operating room, a child’s fear of the unknown is replaced with predictability and understanding [8]. This process aligns with principles of cognitive-behavioral therapy, where demystifying a stressful event helps to correct maladaptive thoughts and reduce anticipatory anxiety [36]. Furthermore, the interactive nature of these tools can instill a sense of agency and control in children, directly counteracting the feelings of powerlessness that often fuel preoperative anxiety.

This dual-action approach helps explain why these digital interventions often outperform traditional nonpharmacological methods [37]. While printed materials are static and verbal explanations can be difficult for young, distressed children to process, a digital narrative is dynamic and developmentally appropriate [8]. This is especially true for younger children, who are more receptive to narrative-based learning and “magical thinking,” making them ideal candidates for story-based interventions [38]. Ultimately, the interventions included in our

XSL•FO
RenderX

review represent a sophisticated evolution of patient preparation, leveraging technology to create experiences that are not only distracting but also educational and empowering, leading to the substantial reductions in anxiety observed in our meta-analysis [39].

Limitations

Despite the promising findings, several limitations should be considered when interpreting this review. First, the overall certainty of evidence was limited by risk of bias, with most trials judged as high risk, particularly in the RoB 2 domain related to deviations from intended interventions, as blinding of participants and personnel was not feasible for interactive digital tools (eg, VR or AR and app-based preparation). This lack of blinding may have introduced performance bias, potentially inflating the observed intervention effects, especially for subjective anxiety outcomes [28].

Second, substantial clinical and methodological heterogeneity was present across studies, including differences in intervention type and duration, surgical settings, timing of delivery, and outcome assessment points. This heterogeneity represents a key source of uncertainty and limits the interpretability and generalizability of the pooled findings. In particular, variability in intervention modality (eg, VR, AR, and digital storytelling), differences in delivery timing (immediate vs days before surgery), and diversity in patient populations (age ranges and surgical types) may have contributed to the observed inconsistency in effect sizes.

An additional limitation relates to the heterogeneity of outcome measures. The included studies used a range of anxiety instruments, including observer-rated tools (eg, mYPAS) and self-report measures (eg, STAI or VAS), which capture different dimensions of anxiety (behavioral vs subjective). Although the use of SMDs enables statistical pooling across scales, it does not fully address conceptual differences between instruments. These differences may result in nonequivalent outcome constructs being combined, thereby contributing to statistical heterogeneity and uncertainty in the pooled estimate. Therefore, the pooled estimate should be interpreted with caution, as it may combine outcomes that are not entirely equivalent.

Third, only a subset of studies provided sufficient and comparable outcome data for meta-analysis, and most eligible studies were synthesized narratively, which may reduce the precision of pooled estimates. The small number of studies included in the meta-analysis (n=5) also limited the feasibility of conducting subgroup or sensitivity analyses, restricting further exploration of potential sources of heterogeneity. Publication bias could not be reliably assessed because fewer than 10 studies were included in the quantitative synthesis.

Finally, some trials included broader pediatric age ranges than initially planned, and relatively few studies assessed secondary outcomes such as parental anxiety, adherence, postoperative behavioral changes, or longer-term recovery, limiting conclusions regarding the wider impact of these interventions on families and perioperative outcomes. Taken together, these limitations indicate that the findings should be interpreted as indicative rather than definitive, and highlight the need for more standardized, high-quality studies to strengthen the evidence base.

Implications for Practice and Research

The results of this review suggest that immersive and storytelling-based technologies represent a feasible, engaging, and effective adjunct to conventional preoperative preparation. Their scalability and adaptability across cultural and clinical settings make them attractive options in pediatric care. To strengthen the evidence base, future trials should focus on improving methodological rigor, particularly with respect to blinding and standardized reporting.

Implementation feasibility may differ across contexts. In resource-rich perioperative units, VR or AR headsets may offer strong engagement but require equipment, staff support, and infection-control processes. In lower-resource settings or high-throughput outpatient clinics, tablet-based storytelling apps or brief mobile interventions may represent more practical and scalable alternatives. Further research should also investigate cost-effectiveness, age-specific preferences, and the differential value of narrative vs nonnarrative content. Importantly, studies should extend beyond immediate preoperative anxiety to examine outcomes such as postoperative behavior, recovery, and parental well-being, which are critical to holistic perioperative care.

Conclusions

This systematic review and meta-analysis synthesized and critically appraised the available evidence on the effects of digital storytelling and immersive technology–based interventions on preoperative anxiety in pediatric patients undergoing elective surgery. Overall, the included studies suggest a trend toward reduced preoperative anxiety in children receiving digital interventions compared with standard care. However, the certainty of this evidence is limited. The pooled meta-analytic estimate should be interpreted with considerable caution due to substantial heterogeneity, the small number of studies included in the quantitative synthesis, and the overall risk of bias across trials. In addition, variability in intervention types (eg, VR, AR, and narrative-based applications), outcome measures, and study designs limits the ability to draw definitive or generalizable conclusions. While these interventions appear to be feasible and engaging approaches to preoperative preparation, current evidence does not allow firm conclusions regarding their comparative effectiveness or optimal implementation. Future high-quality studies with standardized outcome measures, clearly defined intervention protocols, and robust methodological design are needed. Further research should also examine parental anxiety, cost-effectiveness, and longer-term postoperative outcomes to better inform clinical practice.
