Abstract

Background: Iron chelation therapy (ICT) is essential for people with hematological disorders requiring chronic transfusions to minimize the risk of iron overload, yet suboptimal adherence is prevalent. Widespread use of personal technology makes mobile health (mHealth) an attractive platform to promote adherence.

Objective: This study aimed to examine access to mobile technology and preferences for an mHealth intervention to improve adherence to ICT.

Methods: A cross-sectional survey that included 63 items assessing technology access, mHealth preferences, and demographics was administered through REDCap (Research Electronic Data Capture), a digital research data tool, during packed red blood cell transfusion visits. Parents of children receiving chronic transfusions, as well as adolescents and young adults receiving chronic transfusions, were enrolled between August 2018 and June 2019. Patients had to have a hematologic diagnosis requiring chronic transfusions, be receiving ICT, and be aged 12 years or older to complete the survey. Parents were required to have a child aged 24 months who met these criteria.

Results: A total of 60 participants were included (median age 31.5, IQR 20-39 years; n=40, 67% female), with 29 (48%) being parents and 31 (52%) being patients. All parents and patients owned an electronic tablet, a smartphone, or both. The most endorsed mHealth app features among all participants included laboratory test monitoring (55/60, 92%), reminders to take iron chelation medication (50/60, 83%), and education about ICT (49/60, 82%). Parents' most endorsed features included laboratory test monitoring (27/29, 93%) and education about ICT (25/29, 86%). Patients' most endorsed features included laboratory test monitoring (28/31, 90%) and reminders to take iron chelation medication (28/31, 90%). There were no substantial differences between parents and patients in their preferences.

Conclusions: Both parents and adolescents and young adults reported a strong interest in multiple mHealth app features. Participants provided valuable insights into optimal strategies and preferred app features for developing a multifunctional technology-based behavioral intervention to promote ICT adherence.

Introduction

Iron overload is the major cause of morbidity and mortality in transfusion-dependent hematological disorders such as thalassemia [1]. One of the cornerstones of treatment for refractory anemia is packed red blood cell transfusions. Over time, transfusions can lead to excess iron accumulation in the heart, liver, and spleen, among other tissues, leading to a wide array of complications, including endocrinopathies, cardiomyopathies, and hepatic failure.

Iron chelation therapy (ICT) is essential for people with thalassemia and other hematological disorders requiring long-term red blood cell transfusion to minimize the risk of iron overload. Previous work has shown that adherence varies widely and is often suboptimal [2-5]. Suboptimal adherence to iron chelation medication is prevalent and has been associated with an increased risk of iron overload, resulting in increased morbidity, mortality, and health care use. Thus, interventions to improve ICT adherence are important to investigate and essential to improving morbidity and mortality.

Medication adherence is complex and multifaceted [6,7] Studies of adherence among patients taking iron chelation medication often report multiple factors contributing to low adherence, and it is difficult to compare and establish rates of adherence among patients taking iron chelation medication [2,3]. One potential avenue to address and improve adherence to medications is through the development of mobile health (mHealth) tools, that is, the use of mobile and wireless applications (eg, SMS text messaging, apps, wearable devices, remote sensing, and social media) in the delivery of health-related services [7,8]. The most recent (2021) Pew Research Center survey found that 97% of adult US residents owned a mobile phone, with 85% owning a smartphone [9]. Similarly, the vast majority of adolescents have access to digital devices, including smartphones (95%), and 97% of all adolescents report using the internet daily [10].

However, while the Pew Research Center surveys are designed to sample a population that reflects the demographics of the United States, they do not necessarily reflect the demographics of individuals with chronic medical conditions such as thalassemia and their families. There is a known “digital divide” in the United States, with disparities in access to technology correlated with a variety of factors, including household income, educational level, and geography [11]. It is important to ensure that pediatric patients, adolescents, and young adults receiving chronic transfusions, as well as parents, have access to technology when considering mHealth interventions.

Moreover, there is a variety of potential avenues and tools that can be integrated into mHealth interventions. Observational studies have shown that sharing health care experiences online can lead to decreased isolation, increased support, an exchange of coping strategies, and health care learning from shared experience [12]. There is also some evidence that both healthy adolescents and those with chronic health conditions who develop skills to monitor their symptoms and self-manage their health may experience improved outcomes in disease knowledge and adherence specifically through SMS text messaging and mobile phone apps [13-16]. A pilot study of a medication reminder app demonstrated the feasibility and potential usefulness of mHealth in adolescents and young adults receiving chronic transfusions [17]. In addition to access to mHealth and the efficacy of these features, it is important that mHealth interventions have high engagement. While adolescents in general are avid smartphone users, only 2% of adolescents report frequent use of an mHealth app [18]. Thus, it is crucial that mHealth interventions are designed with accessibility and engagement in mind.

Involving users in the early development process has been shown to promote engagement [19,20]. User-centered app design is a method of designing mobile apps that begins with a needs assessment followed by iterative cycles involving the intended end user. Apps involving end-user input throughout the development, testing, and dissemination process are more likely to be perceived by users as useful as well as easy to use [21].

Thus, this study was a needs assessment for an mHealth adherence app as the first step in a user-centered design process. First, we aimed to evaluate patients’ and parents’ access to technology-based (mHealth) interventions. Second, we aimed to assess interest in and preferences for an mHealth intervention to promote ICT adherence. We hypothesized that adolescents and young adults and parents of children receiving chronic transfusions would have high interest in an mHealth app and that adolescents and young adults and parents may have different preferences and priorities for mHealth. Ultimately, this study is the first step in developing an mHealth tool to promote medication adherence and optimize health outcomes among patients receiving chronic transfusions.

Methods

Recruitment

This was a cross-sectional, single-institution study. Participants completed a cross-sectional survey that was administered through REDCap (Research Electronic Data Capture; Vanderbilt University; a secure, web-based tool for research data capture used for collecting data and surveys) using tablet computers during packed red blood cell transfusion visits at a single institution. Eligibility criteria for patients included (1) having a hematologic diagnosis requiring chronic transfusions, (2) being on ICT, and (3) being aged 12 years or older to complete the survey. Parents were required to have a child aged 24 months or older who met these criteria. Potential study participants (parents of children receiving chronic transfusions and adolescents and young adults receiving chronic transfusions) were approached during transfusion appointments between August 2018 and June 2019. Data were collected on electronic tablets through REDCap supported by the Northwestern University Clinical and Translational Sciences Institute. This study aimed to accrue 50 to 100 patients based on feasibility and patient volume at our infusion center. By the end of the accrual period, a total of 60 participants were enrolled.

Ethical Considerations

The institutional review board at the Ann and Robert H. Lurie Children’s Hospital of Chicago approved this study, and all procedures were conducted in accordance with the current

XSL•FO
RenderX

version of the Declaration of Helsinki. Informed consent was obtained from all participants, and they were aware of their ability to opt out. Survey data were anonymous and did not contain identifying information. All participants were compensated with a US $25 gift card upon successful completion of the study survey.

Study Measures

Our study instrument included 63 items assessing technology access, mHealth preferences, and demographics. These items were based on current literature investigating technology-based interventions and medication adherence among patients with chronic conditions in adult and pediatric populations based on previous studies conducted at our institution [6,16,22-24].

The technology access portion of the survey included 7 questions about access to electronic devices, as well as 8 questions about SMS text message and call limits and home or school internet signal strength. The mHealth portion of the survey included 8 yes-or-no questions, 1 rank-order question, and 6 multiple-choice questions that evaluated interest in general mHealth features and notification preferences, which have been previously reported in studies conducted at our institution [16,23].

Statistical Analysis

Descriptive statistics for categorical data were reported in frequencies and percentages. Chi-square tests were run to determine the significant associations among variables and different subgroups. All tests were 2-sided, and a *P* value of <.05 was considered statistically significant. Statistical analysis was conducted using Microsoft Excel.

Results

Demographics and Technology Access

A total of 60 participants were included, with 29 (48%) being parents and 31 (52%) being patients (Table 1). The median age of the participants was 31.5 (IQR 20-39) years, and 67% (n=40) were female. The most common diagnoses included thalassemia (n=31, 52%) and sickle cell disease (n=21, 35%). Reported ICT medications varied, with 65% (n=39) taking deferasirox in oral formulation, 27% (n=16) taking deferasirox in tablet form, 8% (n=5) taking deferiprone, and 5% (n=3) taking deferoxamine. All participants' characteristics are summarized in Table 1.

All parents and patients owned an electronic tablet, a smartphone, or both. Most parents and patients owned cell phones (28/29, 97% and 28/31, 90%, respectively), but tablet ownership was less pervasive (19/29, 66% and 10/31, 32%, respectively). Most parents and patients had unlimited plans for SMS text messaging (27/29, 93% and 25/31, 81%, respectively) and data (21/29, 72% and 21/31, 68%, respectively), as well as a fast home internet connection (24/29, 83% and 23/31, 74%, respectively).

[a]Other hematological disorders among participants included sideroblastic anemia (1/60, 2%), Diamond-Blackfan anemia (3/60, 5%), congenital dyserythropoietic anemia (2/60, 3%), Fanconi anemia (1/60, 2%), and pyruvate kinase deficiency (1/60, 2%).

[b]Other medications included ibuprofen (1/60, 2%), betamethasone ointment (1/60, 2%), risedronate (1/60, 2%), levothyroxine (1/60, 1.7%), hormonal replacement therapy (1/60, 2%), medroxyprogesterone (1/60, 2%), wellbutrin (1/60, 2%), venlafaxine (1/60, 2%), enalapril (1/60, 2%), hydrocortisone (1/60, 2%), hydroxychloroquine (1/60, 2%), oral contraceptive pills (1/60, 2%), aspirin (1/60, 2%), and unspecified medications (3/60, 5%).

Interest in mHealth Features

All 8 proposed mHealth features were endorsed by over 50% (30/60) of the participants, including parents (15/29, 52%) and patients (16/31, 52%; Table 2). The median number of features endorsed by both parents and patients was 7 (IQR 6-8). The most endorsed mHealth app features among parents and patients included laboratory test monitoring (55/60, 92%), reminders to take iron chelation medication (50/60, 83%), and education

XSL•FO
RenderX

about ICT (49/60, 82%). In particular, parents' most endorsed features included laboratory test monitoring (27/29, 93%) and education about ICT (25/29, 86%). Patients' most endorsed features included laboratory test monitoring (28/31, 90%) and reminders to take iron chelation medication (28/31, 90%). There were no significant differences between parents and patients in their preferences (Table 2).

Table . Frequency of participants' reported interest in general mobile health features as assessed via a cross-sectional survey (N=60).

App feature	All participants, n (%)	Parents (n=29), n (%)	Patients (n=31), n (%)	*P* value
Medication reminders	50 (83)	22 (76)	28 (90)	.13
Medication log	45 (75)	23 (79)	22 (71)	.46
Positive feedback	47 (78)	20 (69)	27 (87)	.09
Adherence SMS text message prompt	48 (80)	21 (72)	27 (87)	.16
Social media	39 (65)	20 (69)	19 (61)	.53
Diagnosis education	45 (75)	23 (79)	22 (71)	.46
Medication education	49 (82)	25 (86)	24 (77)	.38
Laboratory test monitoring	55 (92)	27 (93)	28 (90)	.70

The cumulative ranking of the proposed smartphone app features among parents and adolescents and young adults is summarized in Figure 1. Medication reminders (8/29, 28%) were most frequently ranked as most important among parents, followed by the ability to review laboratory test results (7/29, 24%) and social media features (3/29, 10%). Patients also most prioritized medication reminders (12/31, 39%), followed by laboratory test results (6/31, 19%) and social media features (3/31, 10%).

Discussion

Principal Results

Our study aims were to evaluate patients' and parents' access to technology-based (mHealth) interventions and assess interest in and preferences for an mHealth intervention to promote ICT adherence. These findings highlight that parents and adolescents and young adults had high rates of technology access and reported strong interest in multiple mHealth app features, including features that specifically focused on medication adherence, education, and connection with the community.

Our participants' high rate of technology access is comparable to that in reports of the general population and supports that mHealth interventions may be an accessible, useful tool to promote adherence [10,12]. Our study adds to the existing literature by demonstrating a strong interest in multiple mHealth app features by patients receiving chronic transfusions. Participants provided important insights into preferred app features for developing a technology-based behavioral intervention (mHealth app). These findings can help guide the development of an effective mHealth tool to promote ICT adherence for adolescents and young adults with thalassemia or other chronic transfusion–dependent conditions.

While there are some limited mHealth apps currently available, the strong interest from both patients and parents in mHealth features in our study suggests that there may be some features and tools that would be more beneficial and engaging to users than those that currently exist. This further highlights the importance of user-centered development in ensuring that these apps prioritize features that are of interest to the populations that are intended to use them. One international study in 2018 found that, although there are currently many mHealth apps available for use, they often do not match patients' expectations due to lack of user-centered development [24]. Our study represents the starting point of user-centered design and assessment of interest in mHealth interventions and features among patients receiving ICT and their parents. User-centered design should continue throughout the phases of development, including creation, deployment, testing, implementation, and dissemination [21].

Of the app features highlighted in our study, there was particularly strong interest in laboratory test monitoring, medication reminders, and social media or virtual connections with other patients with transfusion-dependent illnesses. Of note, there was no statistically significant difference between the mHealth preferences of parents and patients surveyed, with a nonsignificant but slightly greater proportion of patients preferring positive feedback when taking medications compared to parents. Prior literature has often highlighted the ways in which barriers to adherence may vary from adolescence to adulthood and the ways in which adolescents may have unique preferences for mHealth interventions due to their relative use of technology compared to other age groups [25-27]. One possible explanation for the lack of discrepancy between the preferences of parents and patients is that most participants had interest in multiple mHealth features, with a median number of features endorsed of 7 out of 8. An mHealth tool with multiple features may be beneficial to both patients receiving ICT and parents.

This study builds on previous literature examining adherence interventions for patients receiving ICT [2-4,17]. In particular, a 2017 study highlighted a pilot intervention using a medication reminder app and demonstrated the feasibility and potential usefulness of mHealth in adolescents and young adults receiving chronic transfusions. Our study was focused more on the development stages of an mHealth intervention, particularly on obtaining user-centered feedback on which features might be preferred and promote adherence. Moreover, our study examined not only adolescents and young adults but also parents, who are also a potential user group for an mHealth intervention.

The results of this study are consistent with the literature on technology access and preferences among patients with other complex chronic conditions, including cystic fibrosis, diabetes, sickle cell disease, and acute lymphoblastic leukemia [16,23,28-30]. This further supports that an mHealth app with multiple features could be a promising tool to promote ICT adherence in patients receiving chronic transfusions.

Strengths

Our study had several strengths. We were able to conduct a thorough evaluation of access to technology, assessing both access to multiple modes of technology and barriers to technology use, such as data plans and Wi-Fi access. Moreover, this study examined both patients' and parents' preferences for an ICT mHealth app, allowing us to effectively examine a group of all potential users of this mHealth intervention while also comparing preferences. Lastly, our patient population was diverse, both racially and ethnically and in terms of ICT medications used, as well as in insurance status.

Limitations

There are several limitations worth noting in this study. First, this was a single-institution study with a relatively small sample size. While our survey items were not validated, they have been used in other published studies [16,22]. Additionally, as we adapted existing survey items, we did not provide an exhaustive list of potential mHealth interventions and app features. Finally, we did not survey our participants about prior experience with mHealth apps, which may have been helpful to note in participants' perceptions of mHealth and preferences for mHealth features.

Conclusions

In conclusion, parents and patients reported high accessibility to mobile technology. Overall, there was a high level of interest in mHealth interventions, as well as in features specifically intended to promote medication adherence. These findings support an interest in and need for the development of a user-centered mHealth intervention as a tool to promote medication adherence among patients with thalassemia and other conditions requiring chronic transfusions, as well as among their parents. Parents and patients reported similar preferences for mHealth features centered on medication reminders, education, and connection with the broader community of individuals requiring chronic transfusions and their families. In

XSL•FO
RenderX

the future, continuing to center user experiences and feedback will be important in maximizing engagement with and utility of an app as an intervention to improve adherence and health care outcomes among patients receiving ICT.

Next steps may include developing and designing an app for an mHealth intervention integrating participant preferences. Throughout development and implementation, centering user experience will continue to be important. Future studies could then use participant feedback to assess the effectiveness of these tools in promoting medication adherence and optimizing health outcomes while also modifying the mHealth tools to be more effective among patients and parents of individuals receiving chronic transfusions.

Abstract

Background: Singapore is a multicultural society characterized by a diverse array of ethnic groups, including Chinese, Malay, Indians, and others. A considerable percentage of Singaporeans are active users of the internet. The internet has become a significant resource for health education, particularly for women who wish to learn about a healthy lifestyle during pregnancy. However, it is still unclear how pregnant women search for information online, particularly within specific groups.

Objective: This study aimed to explore the relationship between healthy lifestyle practices, online health information-seeking behaviors, and internet usage (IU) among 1905 pregnant women.

Methods: Structural equation modeling (SEM) was used to evaluate the relationships between the appropriate intake of food groups, healthy diet practices (HD), internet for dietary advice (ID), internet for physical activity advice (IP), and IU, based on 5 hypotheses rooted in theoretical concepts. We used a multigroup SEM approach to examine these hypotheses across various ages, ethnicities, BMI, and categories of pregnant groups.

Results: Our results confirmed 5 hypotheses, indicating significant relationships among the variables: appropriate intake of food groups was positively linked to HD (β=0.262; *P*<.001); HD was positively linked to ID (β=.168; *P*<.001); ID was positively linked to IP (β=0.185; *P*<.001); IP was positively linked to IU (β=0.190; *P*<.001); and HD was negatively linked to IU (β=−0.208; *P*<.001). The multigroup SEM analyses yielded significant differences in Hypotheses 2 and 3 when comparing different age groups (*P*=.009), BMI categories (*P*=.03), and number of pregnancies (*P*=.003).

Conclusions: Our findings offer valuable insights into developing customized online interventions aimed at encouraging a healthy lifestyle during pregnancy.

KEYWORDS

healthy lifestyle practices; online health information-seeking behaviors; internet usage; pregnant women; multigroup structural equation model

Introduction

A healthy lifestyle during pregnancy, including physical activity along with a healthy diet, is beneficial for pregnant women in terms of reducing the risk of maternal and fetal complications [1,2]. With the recent rapid advancement of information and communication technology over the past 2 decades, the internet has emerged as a prominent health education resource for women seeking to learn about dietary and lifestyle modifications during pregnancy [3]. In Singapore, 92.3% of residents are internet users, as indicated by statistics from Global Digital Insights 2025 [4]. Evidence indicates that pregnant women actively use the internet to seek out pregnancy-related information and engage in discussions with peers [5]. Given that the internet serves as a medium for health education, there is a notable lack of investigation into how healthy lifestyles impact online health information-seeking behaviors and internet usage (IU) among pregnant women.

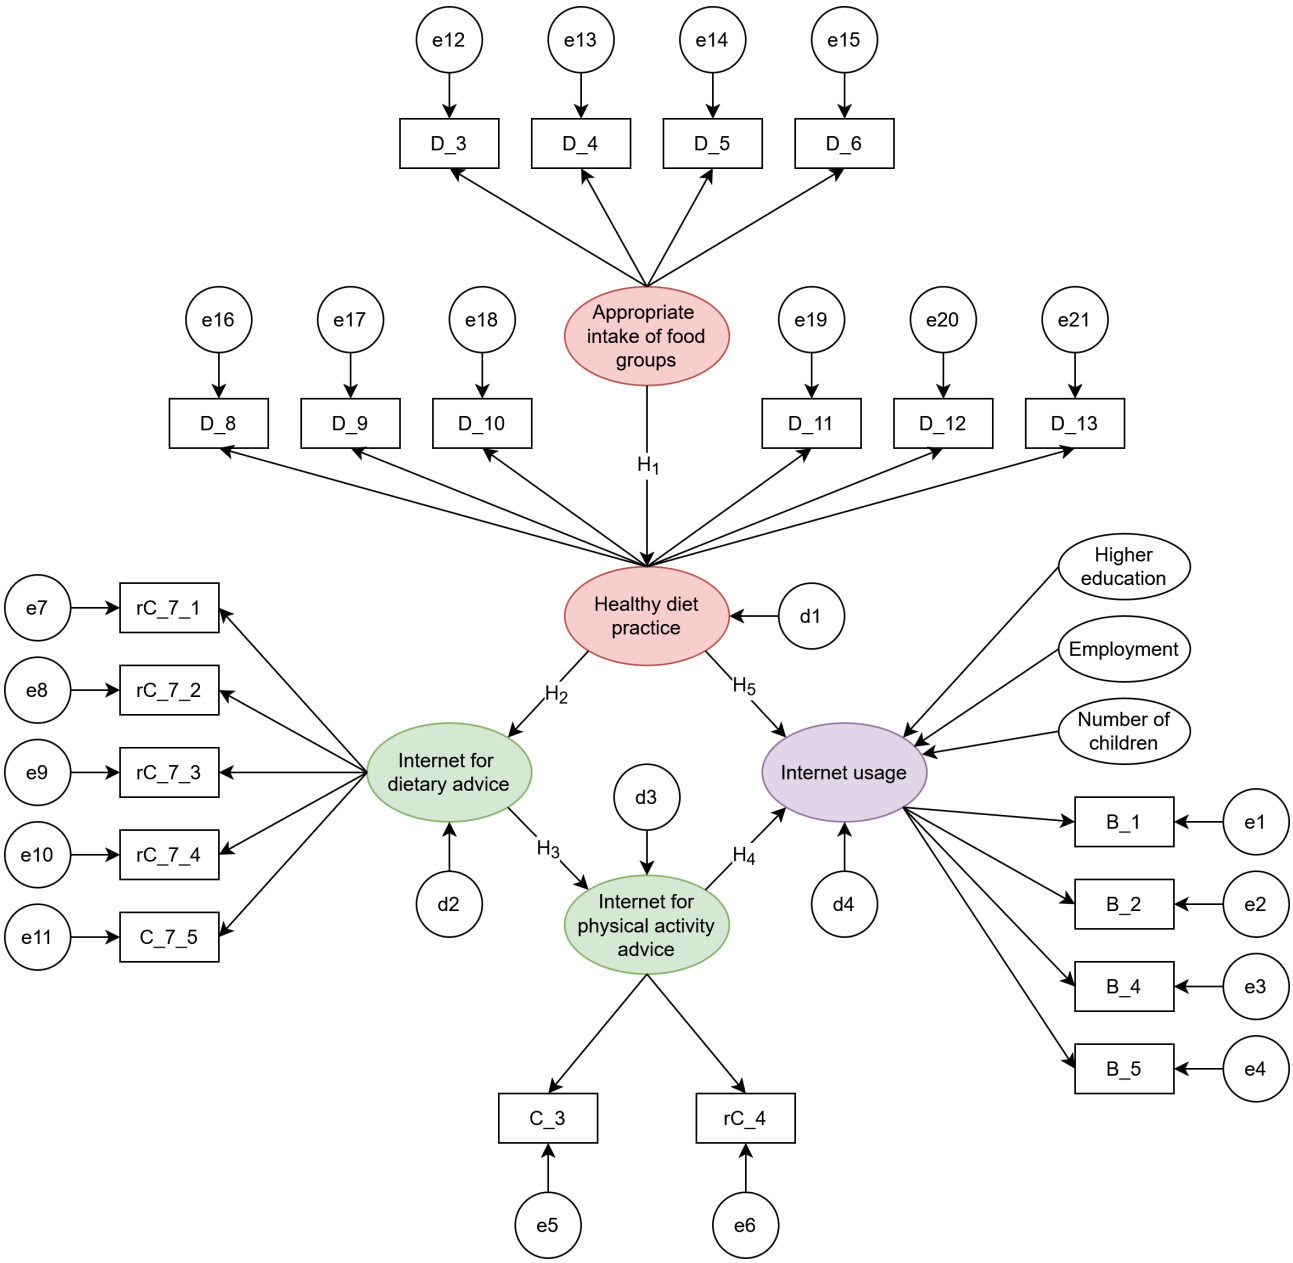
XSL•FO
RenderX

The selection of appropriate food group intake is essential during pregnancy because pregnancy heightens nutritional awareness; thereby, it can help establish healthy dietary practices [6]. Given that the internet serves as a valuable resource for seeking information, pregnant women rely on it to make informed lifestyle choices, encompassing physical activity and healthy eating [7]. A systematic review observed that health information-seeking internet behaviors among pregnant women, especially first-time and young pregnant women, were more likely to find internet-based information [5]. Furthermore, a systematic review revealed that internet use was positively correlated with an increased likelihood of being overweight and obese in the general population [8]. However, it remains unclear whether this conclusion applies to pregnant women.

There are inconsistent findings concerning the relationship between IU and the lifestyle of pregnant women across various countries and ethnic groups, including Iran [9] and Qatar [10]. We found that there is a significant positive relationship between using the internet for healthy behaviors and positive lifestyle changes in Qatari pregnant women [10]. However, 1 study showed no statistical correlation between online health information and a healthy lifestyle in Iranian pregnant women [9]. This discrepancy may be associated with the unique cultural values and beliefs of different ethnic groups. Singapore is a multiracial and multicultural nation, comprising Chinese, Malay, Indian, and various other ethnic groups, all of which contribute to its rich and diverse cultural landscape. Since Singapore is a multicultural country, various ethnic groups may impact these relationships.

This study aimed to investigate the connections among the appropriateness of food group intake, use of online resources for diet and exercise, and IU among pregnant women. A hypothetical model was developed based on protection motivation theory (PMT) [11] and self-control theory (SCT) [12]. The PMT was used to elucidate how pregnant women determine whether to engage in protective behaviors when confronted with a threat by examining the cognitive processes involved in threat and coping appraisal [13]. Pregnant women may pose risks to their unborn babies during pregnancy, yet they are often more inclined to adopt a healthy lifestyle to ensure the safety and development of their child [14]. PMT suggests that pregnant women are more likely than the general population to be motivated by protection, prompting them to actively seek health-related information online regarding a healthy diet and lifestyle [11].

According to the SCT, self-control is the ability to regulate current thoughts, feelings, and behavior to secure future benefits [15], which is very important for health and well-being and involves the repeated act of overriding a dominant response [16]. This trait can manifest in behaviors such as adopting an unhealthy lifestyle prior to pregnancy or spending excessive time browsing irrelevant information online [17]. Pregnant women who exhibit high self-control may prioritize an optimal lifestyle by exerting efforts in self-regulation [15,17]. Therefore, pregnant women who intentionally seek the internet for healthy diets may benefit from the deliberative control process, allowing them to more effectively resist the temptation of high-energy foods and irrelevant online information [12]. Based on these theories, we concluded that there could be potential relationships between IU and healthy lifestyles among pregnant women (Figure 1). It is still unclear whether the hypothetical relationships operated in the same way across different groups, particularly among those of varying ages, ethnicities, BMIs, and numbers of pregnant individuals.



Thus, our study sought to assess these relationships based on five hypotheses (H):

1. Hypothesis 1: Appropriate intake of food groups is linked to healthy diet practice
2. Hypothesis 2: Healthy diet practice is linked to seeking dietary advice on the internet
3. Hypothesis 3: The internet's advice on diet is linked to the pursuit of physical activity advice found on the internet
4. Hypothesis 4: The internet's advice on physical activity is linked to IU
5. Hypothesis 5: Healthy diet practice is linked to IU

Furthermore, we also compare these hypotheses across various ages, ethnicities, BMIs, and numbers of pregnant groups. Such information is crucial for obtaining insights that can guide future targeted interventions for pregnant women.

Methods

Study Design and Data Collection

We conducted this explanatory cross-sectional study among pregnant women who visited 2 antenatal clinics at a university-affiliated hospital in Singapore. There was a public antenatal clinic that served individuals from various economic backgrounds and a private antenatal clinic that catered to those from middle and upper economic classes. We collected data from both clinics, representing a range of socio-economic classes. Data collection occurred while pregnant women were waiting at both clinics. A convenience sampling method was used because of resource constraints. The inclusion criteria were as follows: (1) a minimum age of 21 years, (2) pregnancy in the second trimester (12 to 24 wk of gestation), (3) proficiency in English, and (4) regular access to the internet. A sample size of 1054 was deemed necessary, taking into account a margin of error of 2%, a confidence level of 95%, and a presumed population size of 20,000 [18]. The final anticipated sample size was 1270, which further accounted for a presumed response rate of 83% [19].

Two experienced research assistants (SHW and WWA) recruited all eligible participants in both clinics during the waiting period for their scheduled antenatal follow-up. The research assistants identified moments that were less stressful and more conducive to thoughtful responses, such as right after registration, after checking vital signs, or while participants were waiting for examination results. The research assistants offered a thorough

XSL•FO
RenderX

explanation of the study and invited participants to pose any questions they might have. The research assistants made it clear that choosing not to participate would not impact their antenatal care, and participation was entirely voluntary. We allowed sufficient time for each participant to consider their participation in the study. We acquired their written informed consent prior to the commencement of data collection. A self-administered structured questionnaire was designed to be completed in approximately 10 to 15 minutes. This research was carried out in accordance with the STROBE (Strengthening the Reporting of Observational Studies in Epidemiology) guideline to guarantee the quality of the study (Checklist 1).

Measurements

The study used a package of questionnaires that included demographic and obstetric characteristics, such as age, pre-pregnancy weight and height, race, educational level, employment status, method of conception, number of pregnancies, and number of children, along with 3 validated measures. Classification of BMI groups was based on Singaporean adults [20]: underweight (BMI <18.5 kg/m^2), normal (BMI 18.5 - 22.9 kg/m^2), overweight (BMI 23 - 27.4 kg/m^2), and obese (BMI ≥27.5 kg/m^2).

The Rapid Eating and Activity Assessment for Participants Short Version

The diet was assessed using the 16-item Rapid Eating Assessment for Participant-Shortened version (REAP-S) [21]. The REAP-S questionnaire was designed for adequacy and excess intake of fat, cholesterol, fiber, sugar, and selected food groups [21]. The questionnaire contains 16 items featured with a binary scale (ie, yes or no), a 3-point scale (ie, from usually or often to rarely or never), and a 5-point Likert scale (ie, from not at all to very willing). A higher score indicated healthy diet intake. The scale has been validated with the Block 1998 food frequency questionnaire [21]. Good internal consistency (Cronbach α=.72) [22] and good test-retest reliability (r=0.86) were reported [23]. Our study indicated a Cronbach α value of .7.

Internet for Physical Activity and Nutrition Scale

A 7-item Internet for Physical Activity and Nutrition Scale (IPAS) was adopted to investigate associations between healthy lifestyles and internet use from 1 session of a survey instrument [24,25]. The question types included both dichotomous (yes or no) and ordinal 5-point Likert scales. The items included both positives and negatives. We reversed the negative items before conducting the data analysis. A higher score indicated greater levels of physical activity and adherence to a healthy diet obtained from the internet. We found that this scale demonstrated acceptable internal consistency (Cronbach α=.7).

Internet Frequency Usage Scale (IFUS)

We created a 6-item Internet Frequency Usage Scale (IFUS) to evaluate the frequency of internet use, drawing on the concepts of the existing IU scale [26]. We adjusted the items to assess the frequency of internet access across various activities, including social media, gaming, emails, and online messaging applications. The sample item was, “On average, how many hours do you spend on social media (Facebook, Twitter, or others) every day?” The scale was designed to be self-completed by answering to what extent they had accessed the internet every day on a 5-point Likert scale from <1 hour (1) to >4 hours (5). The higher the score, the longer the duration of the IU. Cronbach α was calculated to be .7 in this study, indicating an acceptable level of internal consistency.

Statistical Analysis

R software (version 4.3.2; R Core Team) [27] was used for descriptive and inferential statistical analysis, including Bonferroni-corrected chi-squared tests and 2-sample 2-tailed t tests. SAS (version 9.4; SAS Institute Inc) [28] was used for simultaneously examining the hypothesized associations through a structural equation modeling (SEM) approach [29]. Given that there were dichotomous responses in the IPAS, we applied the Satorra-Bentler corrections to the chi-square statistic and standard errors to address the non-normality of our data, in conjunction with the normal-theory maximum likelihood estimator [30]. We addressed missing data using two methods: listwise deletion and imputation. For the demographic data, we opted for listwise deletion to handle the missing information effectively. For each item in the questionnaire, we used imputation to tackle the missing data. Binary response items were imputed using the discriminant function method [31], while all other response items were imputed through regression [32].

A series of exploratory factor analyses was used to identify the structure of variables, while confirmatory factor analyses (CFA) were adopted to test a prespecified theoretical model [33]. Items with a factor loading <0.30 or a communality <0.10 were excluded due to inadequate explanation of the proposed constructs [34]. Modification indices (MI) were used to improve the fitness of models. Goodness-of-fit criteria for the model fit included a ratio of chi-square to its degree of freedom <5, an incremental fit index >0.90, a Tucker-Lewis index >0.90, a comparative fit index >0.90, and a root mean square error of approximation <0.06 [35,36].

A multigroup SEM was performed to compare our 5 hypotheses across different ages (<30, ≥30 - 34, or >35), ethnicities (Chinese, Malay, Indian, or others), BMIs (underweight, normal, overweight, or obese), and numbers of pregnant (primigravida or multigravida) groups. We quantified these relationships as standardized coefficients (β), estimating them with equal factor loadings across the multigroup by establishing metric equivalence to ensure accurate comparisons through chi-squared tests [37]. A P value of .05 indicates statistically significant differences among the multiple groups.

Ethical Considerations

The National Health Care Group Domain Specific Review Board (NHG DSRB Ref: 2017/00423) conducted a review and granted approval for this study on May 17, 2017. We provided each participant with S $5 (US $3.9) as a token of appreciation for their time. We emphasized the voluntary nature of participants’ involvement and the confidentiality of the information collected. All data were stored in an encrypted file protected by 2-factor authentication. Access to the data was restricted to research

XSL•FO
RenderX

team members only. All participants provided written informed consent.

Results

We approached 2700 women in total, and 2206 of them agreed to participate in our study (response rate=81.7%). The reasons for nonparticipation included fatigue, busy schedules, and commitments to other business activities. Among these participants, 1905 fully disclosed their demographic information. The process of selection is illustrated in Figure 2. Table 1 summarizes the demographic and obstetrical characteristics of participants. The prevalence of underweight, normal weight, overweight, and obese women was 10.18% (194/1905), 48.56% (925/1905), 28.24% (538/1905), and 13.02% (248/1905), respectively. The mean age was 31.24 (SD 4.05) years. The majority were Chinese (800/1905, 41.99%), followed by Malay (466/1905, 24.46%), Indian (364/1905, 19.11%), and others (275/1905, 14.44%). Main participants obtained bachelor's degrees or above (1319/1905, 69.24%) and were full-time workers (1483/1905, 77.8%). We observed significant differences in BMI comparison in ethnicity, education, and number of pregnancies and children.

Figure 2. Respondents' selection process.

The results of exploratory factor analyses and CFAs identified and confirmed a 1-factor structure of IFUS (IU), a 2-factor structure of IPAS (internet for dietary advice and internet for physical activity advice), and a 2-factor structure of REAP-S (appropriate intake of food group and healthy diet practice) after removing inadequate factor loadings. We found that the initial model did not fit well because of model misspecification. Hence, we performed MI by correlating error terms of interpretable covariances based on the evidence. Table 2 presents the median, range, mean, and SD of the IFUS, IPAS, and REAP-S, along with their factor loadings for each item, as determined through the CFAs. The mean (SD) scores for the IFUS, IPAS, and

XSL•FO
RenderX

REAP-S were 9.85 (SD 3.62), 11.99 (SD 2.36), and 23.49 (SD 3.17), respectively. The factor loadings for items across 3 scales ranged from 0.327 to 0.942.

Table . Mean (SD) and median (range) of Internet Frequency Usage Scale, Internet for Physical Activity and Nutrition Scale, and the Rapid Eating Assessment for Participant Shortened Version and subscales, and factor loadings of the items of Internet Frequency Usage Scale, Internet for Physical Activity and Nutrition Scale subscales, and Rapid Eating Assessment for Participant Shortened Version subscales in a series of confirmatory factor analyses.

[a]IFUS: Internet Frequency Usage Scale.

[b]IU: internet usage.

[c]IPAS: Internet for Physical Activity and Nutrition Scale.

[d]IP: Internet for physical activity advice.

[e]r: reversed item.

[f]ID: Internet for dietary advice.

[g]REAP-S: Rapid Eating Assessment for Participant Shortened Version.

[h]AI: Appropriate intakes of food groups.

[i]HD: Healthy diet practice.

Afterwards, we examined the relationships among appropriate intake of food groups (AI), healthy diet practice (HD), internet for dietary advice (ID), internet for physical activity advice (IP), and IU using an SEM approach, as shown in Figure 3. We also added employment, education levels, and the number of children in the SEM for adjustment. Table 3 presents the goodness-of-fit criteria before and after MI for 3 measures and an SEM. The SEM model demonstrated satisfactory goodness-of-fit indices [35,36], with the following results: χ^2/df=3.766 (<5), incremental fit index=0.930 (>0.90), Tucker-Lewis index=0.908 (>0.90), comparative fit index=0.930 (>0.90), and root mean square error of approximation=0.038 (<0.06). Figure 3 suggests that AI was positively linked to HD (β=0.262; *P*<.001); HD was positively linked to ID (β=0.168; *P*<.001); ID was positively linked to IP (β=0.185; *P*<.001); IP was positively linked to IU (β=0.190; *P*<.001); and HD was negatively linked to IU (β=−0.208; *P*<.001). We concluded that the results supported hypotheses H_1–H_5.

Figure 3. A structural equation model of the relationships among study variables (appropriate intakes of food groups, healthy diet practice, internet for dietary advice, internet for physical activity advice, and internet usage) in pregnant women after adjustment of education level, employment status, and number of children. Arrow (→): direct impact; B: Items of Internet Frequency Usage Scale; C: Items of Internet for Physical Activity and Nutrition Scale; D: Items of the Rapid Eating and Activity Assessment for Participant Short Version; d: residue term; e: error term; r: reversed item. * $P < .05$; ** $P < .01$; *** $P < .001$.

In Table 4, we performed 4 multigroup SEMs to test these 5 hypotheses by comparing different ages, ethnicities, BMIs, and numbers of pregnant groups. All multigroup SEM analyses yielded significant results concerning the relationship from AI to HD (Hypothesis 1). For the relationship from HD to ID (Hypothesis 2), nonsignificant findings were observed in underweight pregnant women (P=.94) aged 30 to 34 (P=.05) from other ethnic groups (P=.95). There were notable differences between age groups (<30 vs 30–34, P=.009) and BMI groups (underweight vs overweight, P=.03). For the relationship from ID to IP (Hypothesis 3), no significant results were found in underweight women (P=.27) or first-time pregnant women (P=.30) from the Indian ethnic group (P=.11). We found a significant difference (P=.003) between primigravida and multigravida. Although we observed nonsignificant findings in Hypothesis 4 and Hypothesis 5 for specific ethnic and BMI groups, the comparisons between these groups were insignificant.

Table 5 presents a summary of the outcomes related to 5 hypotheses and 4 comparisons across various age groups, ethnicities, BMIs, and numbers of pregnancies. Based on our study, we supported 5 hypotheses within our hypothetical model that was grounded in the PMT [11] and SCT [12]. To extend our knowledge, we discovered that the hypothetical relationships varied significantly across different age and BMI groups for Hypothesis 2, the number of pregnancies for Hypothesis 3, and ethnic groups for Hypothesis 4.

Discussion

Principal Findings

This study confirmed the 5 hypotheses among pregnant women. For Hypothesis 1, our findings support the relationship between the intake of food groups and healthy diet practice regardless of different groups of age, ethnicity, BMI, and number of pregnancies. Our results revealed that women who had an appropriate intake of various food groups were more likely to maintain a healthy diet, which aligns with the results of a previous study [6]. The findings aligned with the concepts of the PMT [14], indicating that pregnant women adopted protective behaviors to ensure the safety and development of their unborn babies. The pregnant women perceived poor eating habits as a threat to their pregnancy outcomes and used the internet to assist them in maintaining a healthy diet. They did this by choosing appropriate food groups and engaging in healthy dietary practices [11]. Pregnancy offers a valuable opportunity to embrace health-promoting lifestyle behaviors [38], as this is essential for safeguarding the baby's health.

For Hypothesis 2, we supported that women who follow healthy dietary practices are inclined to seek dietary advice from the internet. This result is consistent with a previous narrative review [7]. The potential explanation may relate to the fact that most pregnant women find the internet to be the most convenient source for accessing nutritional information tailored specifically for pregnancy, enabling them to connect their healthy eating behaviors [39]. This finding supports the concept of SCT [12], suggesting the pregnant women regulate thoughts, feelings, and behaviors to secure future benefits of their pregnancy by optimizing their lifestyle [15]. Consequently, pregnant women actively sought online health-related information to guide their dietary choices as part of a control process aimed at making informed decisions [12].

However, Hypothesis 2 became insignificant in underweight women aged 30 to 34 when compared to overweight women aged less than 30, and our multigroup comparisons were significant. The finding may suggest that these women are more cautious about their screen time [40]. In contrast, the use of the internet was found to have a significant positive correlation with overweight and obesity [8]. Additionally, younger women were increasingly inclined to use the internet [5].

For Hypothesis 3, our results confirmed that pregnant women who sought online diet advice were more likely to seek online physical advice. One possibility for these observations was that pregnant women sought to ensure a healthy pregnancy and to make informed decisions about their health and the well-being of their unborn children [7]. Physical activity and healthy eating could help pregnant women achieve the recommended gestational weight gain while minimizing the risk of pregnancy complications [41]. This pattern was consistent with the PMT's theoretical principles [11]; expectant mothers confronted with the threat of pregnancy sought health-related information to ensure a healthy pregnancy [13]. As a result, pregnant women are driven to protect their unborn children by actively seeking internet information about a good diet and lifestyle [14].

Notably, our multigroup SEM comparison revealed a significant difference between primigravida and multigravida. The finding supports previous results indicating that multigravida experience positive outcomes from pregnancy exercises, including improved sleep, reduced stress, decreased back pain, and shorter labor

XSL•FO
RenderX

[42]. Another study suggested that primigravida were more likely to be physically inactive than multigravida, as they tended to pay extra caution regarding their pregnancy [43].

For Hypothesis 4, we found that women who received online physical advice were likely to use the internet. The pattern of this result seems to align with findings from a prior study indicating that more than half of pregnant women use the internet to seek information regarding physical activities [10]. Online platforms enable pregnant women to obtain health advice from various sources, prompting them to invest time in seeking reliable information to ensure safe exercise during pregnancy [5], in accordance with the principle of PMT [14].

Although the multigroup comparisons were not significant, we observed that Hypothesis 4 became nonsignificant in both the Indian and Malay groups. Regional variations and cultural differences may account for the observed disparities in physical activity levels during pregnancy, as suggested by a rapid review [44] and 2 studies [45,46]. Malay and Indian Women from the Malay and Indian communities in Singapore each possess distinct sociocultural environments, characterized by significant variations in cultural practices [47]. For both Indian and Malay pregnant women, cultural values place a strong emphasis on rest and modesty during pregnancy, which may restrict physical activities. It was possible that Malay and Indian women might have been dissuaded from participating in antenatal physical activity due to insufficient and contradictory information stemming from cultural beliefs about exercise and physical activity [45,46].

Multigroup comparison also showed that Malay women who sought advice on physical activity from the internet were significantly less likely to be associated with IU compared to women from other ethnic groups. The possibility is associated with socio-economic disadvantages and limited digital literacy [48], particularly affecting certain Malay households in Singapore [47]. In these households, Malay pregnant women faced challenges stemming from restricted digital access. Malay women may exhibit a lack of confidence in interpreting digital information, which aligns with findings observed in Iran [9].

We found that women in the normal-weight group who received online physical advice were significantly more likely to use the internet than those in the underweight, overweight, and obese groups, according to our multigroup analyses. Underweight pregnant women may experience fatigue and decreased motivation for engaging in physical activities [49]. Overweight and obese pregnant women may exhibit lower motivation to participate in online activities, potentially due to feeling overwhelmed by recommendations for lifestyle changes [50].

For Hypothesis 5, our results revealed that participants with healthy diet practice were significantly negatively associated with IU. This may occur because pregnant women who follow a healthy diet are less likely to rely on the internet for dietary information, as they have already established habits and knowledge about nutrition [51]. Additionally, some individuals who maintain a well-balanced diet may prefer to seek guidance from health care professionals, read books, or consult offline resources instead of browsing online [52]. Some pregnant women expressed that the online information available to them failed to instill the confidence required for effectively managing their health [9].

Another potential reason was that they focused on mindful eating and aimed to decrease screen time for the sake of their overall well-being [53]. All usage of the internet is classified as screen time. Screen watching during meals can distract individuals from truly enjoying their food, potentially hindering their ability to recognize satiety signals, which is an essential aspect of intuitive eating [53]. Hence, limiting screens while eating is often associated with mindful and intuitive eating, which can help develop awareness of hunger and satiety signals [54]. Mindful eating may enhance awareness of daily consumption of nutritious and balanced foods, aid in preventing overeating, and promote better digestion [54].

We observed that Hypothesis 5 became nonsignificant in the Malay group. This pattern indicates that cultural factors and personal habits may influence IU [55,56]. A study indicated that individuals in Malaysia express greater concern for their privacy on social networking platforms; consequently, it was probable that they would also have similar privacy concerns when engaging with IU [55]. Personal habits, like limiting screen time or prioritizing offline activities (reading books or participating in outdoor hobbies), could affect IU [56]. Hence, cultural values and personal preferences play a role in influencing IU.

Strengths and Limitations

This study has several notable strengths. To the best of our knowledge, this study is the first to assess the structural relationships between healthy lifestyle practices, online health information-seeking behaviors, and IU among pregnant women. This evaluation is grounded in the theoretical frameworks of the PMT [11] and SCT [12]. We used multigroup SEM to analyze the structural relationships among various groups. We had a sufficiently large sample size to enhance accuracy, increase statistical power, and bolster confidence in the results.

However, we recognized several limitations in this study. First, because the study is cross-sectional, the findings indicate a temporal relationship rather than a cause-and-effect relationship. Second, using a self-administered questionnaire may introduce recall, informational, and social desirability biases. Furthermore, the reliance on self-reported dietary data lacked objective validation, which could address issues such as portion size misestimation and variability in dietary habits from day to day. Third, since this study only included pregnant women who had made 2 antenatal clinic visits at a hospital, it may not be generalizable to the whole population of pregnant women. Fourth, our study used convenience sampling, which may restrict representativeness and introduce selection bias due to the potential for sampling error. Fifth, while we used validated tools for measuring study variables from other countries, it was essential to culturally adapt them for the local population. Finally, the participants were restricted to women who were proficient in English, which may have resulted in the exclusion of non-English-speaking women. This limitation could potentially affect the generalizability of the findings.

XSL•FO
RenderX

Implications

Our findings have several important implications. A positive relationship exists between healthy lifestyle practices and online health information-seeking behavior, highlighting the specific needs of pregnant women to seek online information that supports their healthy lifestyle choices. Our findings provide important insights into the effectiveness of online interventions designed to promote a healthy lifestyle during pregnancy. A negative relationship exists between healthy dietary practices and IU. This observation highlights the importance of credible online information, as well as cultural values and personal preferences, in shaping how pregnant women use the internet. Monitoring online content by regulatory bodies is important [57]. Health care professionals ought to be equipped to assist pregnant women with retrieving, interpreting, and using online resources [9]. Various age groups, BMI categories, ethnicities, and numbers of pregnancies exhibited alterations in these relationships. These findings assist in designing targeted interventions tailored to specific groups.

Future Research

Future research should adopt a longitudinal multisector design to examine the causal relationships between study variables and enhance the generalizability of the findings. Future research could explore the use of objective measurement tools and probabilistic sampling techniques to reduce biases and errors. To gain a comprehensive understanding of healthy lifestyle practices, online health information-seeking behavior, and IU among pregnant women, there is a need for additional qualitative studies. Future research should explore healthy eating and IU among pregnant women during the first and third trimesters, thereby broadening the understanding beyond the second trimester.

Conclusions

Our study confirms 5 hypotheses and reveals that there are significant structural relationships between healthy lifestyle practices, online health information-seeking behaviors, and IU among pregnant women. The multigroup SEM indicated that age, BMI, ethnicity, and number of pregnancies play a role in affecting these hypotheses. Future research should explore the potential for a longitudinal study to examine causal relationships between the appropriate intake of food groups, adherence to healthy dietary practices, online dietary advice, online physical activity, and IU.

Acknowledgments

The authors would like to acknowledge pregnant women in Singapore who participated in our study.

Funding

The study was funded by Humanities & Social Sciences Seed Fund Grant, National University of Singapore, Singapore (grant number HSS Seed Funding-1/2016, WBS number: R545-000-076-646).

Data Availability

The datasets analyzed in the study are available from the corresponding author upon request.

Authors' Contributions

YL, YTTL, and SHW conceptualized the study. YL and SHW designed the methodology. YY and ZT designed the software. YL, YY, and ZT validated the study. YL, YY, and ZT performed the formal analysis. YL and SHW performed the investigation. YL managed the resources. YL and SHW performed the data curation. YTTL, YY, and YL wrote the original draft. YL, YY, YTTL, ZT, and SHW wrote reviews and editing. YTTL, YY, and YL performed the visualization. YL supervised the project, undertook the project administration and funding acquisition.

Abstract

Background: Oral health in early childhood is vital for long-term well-being, yet dental caries is highly prevalent among young children in the United States, especially in low-income and immigrant families. Brazilian immigrants, a rapidly growing Latin American population in the United States, face distinct barriers to oral health care, such as language differences, limited access to care, and a lack of culturally tailored resources. Despite this, Brazilian immigrants are understudied in public health research. Understanding Brazilian immigrant parents' perspectives is essential to advancing oral health equity through culturally responsive strategies.

Objective: This study aims to understand (1) parents' views on the best ways to support their children's oral health, (2) perceived barriers to oral health care, and (3) preferred methods and strategies for addressing barriers and receiving oral health education and care.

Methods: This qualitative study usedin-depth, semistructured interviews with Brazilian immigrant parents. Guided by the social ecological model, the data were thematically analyzed to identify multilevel influences on oral health behaviors as well as intervention preferences.

Results: Forty-eight Brazilian immigrant parents (29 mothers and 19 fathers) participated. Most had low acculturation levels and lived in primarily Portuguese-speaking households. Parents stressed the need for early, community-based oral health education in schools and daycares. They preferred visual and digital materials, such as videos, apps, and cartoons in Portuguese to overcome language barriers. Parents spoke of language and cultural challenges, limiting access and reducing confidence in navigating care. Access to affordable dental services was a major concern. Parents supported expanded school-based services and culturally welcoming care. Notably, mothers often focused on home routines and navigating systems, while fathers emphasized community outreach and structural barriers.

Conclusions: Brazilian immigrant parents called for linguistically and culturally tailored oral health programs to be offered in trusted community settings, along with improved dental care access through policy changes and expanded insurance coverage. Multilevel strategies addressing both behavioral and systemic barriers show promise in reducing disparities. Future efforts should prioritize the development and evaluation of scalable, culturally responsive models that meet the needs of Brazilian immigrant families.

Introduction

Oral health in early childhood is a critical component of overall child well-being, with lifelong implications for physical, emotional, and social development [1-3]. Despite national efforts to reduce oral health disparities, dental caries is the most common chronic disease among young children in the United States, disproportionately affecting low-income and racial or ethnic minority populations, including immigrant families [4]. According to a recent report by the Centers for Disease Prevention and Control, approximately 11% of children aged 2 to 5 years have one or more primary teeth with untreated decay, and this prevalence is higher among Latino children (eg, Mexican Americans, 18%) [4].

Brazilian immigrants are one of the fastest-growing Latin American populations in the United States yet remain largely understudied in public health research [5]. In recent years, the Brazilian immigrant population in the United States has grown significantly. According to the US Census Bureau, the Brazilian population nationwide has nearly tripled over the past 2 decades, making it one of the fastest-growing immigrant groups [5,6]. Massachusetts is home to approximately 130,323 Brazilian residents—the second-largest Brazilian population in the United States, surpassed only by Florida [5].

Despite this growing presence, Brazilian immigrants often face unique challenges that may not always be addressed in broader Latinx immigrant health research [5,7]. One key distinction is linguistic: Brazilian immigrants primarily speak Portuguese, which sets them apart from other Latin American populations who speak Spanish. This language difference creates specific communication challenges in accessing health care services, including oral health care. It also limits the effectiveness of educational materials and interventions designed for Spanish-speaking populations [5,7].

Much of the existing research on immigrant oral health in the United States focuses on Spanish-speaking communities [8-12], and there remains a limited body of research focused specifically on the oral health of Brazilian immigrant families [6]. Emerging evidence suggests that cultural norms, language barriers, limited access to care, and lack of familiarity with the US health care system can present significant challenges to maintaining oral health among children in Brazilian immigrant households [6].

This research gap presents a significant barrier to developing effective, culturally tailored interventions. Given that cultural and linguistic factors play a critical role in shaping health behaviors and outcomes, especially in oral health, addressing this gap is essential for improving health equity among Brazilian immigrants [6,13,14].

Parents play a central role in shaping their children's oral hygiene behaviors and use of dental services [15-18]. Immigrant parents often face unique systemic and structural barriers that may undermine even strong intentions to support their children's oral health [19-22]. Moreover, public health messaging and health care delivery systems often fail to accommodate the linguistic and cultural needs of Portuguese-speaking immigrant communities [7]. For Brazilian immigrant families in the United States, the intersection of cultural practices, acculturation stress, language barriers, and service inaccessibility creates distinct oral health challenges that are not addressed by most health education efforts [7,23-25].

Community-based and culturally responsive approaches are essential to advancing oral health equity for immigrant populations [19-22]. Frameworks, such as the social ecological model (SEM), provide a valuable lens for understanding how individual, interpersonal, organizational, community, and policy factors influence oral health behaviors and access to dental care [26]. While much of the existing literature has focused on knowledge deficits or service utilization patterns, fewer studies have explored immigrant parents' ideas and recommendations for improving oral health, especially through multilevel intervention strategies addressing education, access, and culturally appropriate care [27-30].

To address noted gaps, this study explored the perspectives of Brazilian immigrant parents living in Massachusetts regarding the challenges and opportunities for promoting early childhood oral health. Specifically, we aimed to understand: (1) parents' views on the best ways to support their children's oral health, (2) perceived barriers to oral health care, and (3) preferred methods and strategies for addressing barriers and receiving oral health education and care. Grounded in the SEM, this qualitative study provides insights that can inform the design of effective, community-based interventions to promote oral health and health equity among Brazilian immigrant populations.

Methods

Study Design

This qualitative study used in-depth, semistructured interviews. In line with qualitative research traditions, this approach enabled the collection of rich, contextualized narratives illuminating how cultural values, parenting practices, and systemic barriers shape health-related behaviors and decision-making in immigrant communities [31,32].

Participant Eligibility and Recruitment

ligibility criteria included (1) self-identifying as a Brazilian immigrant parent, (2) being at least 21 years old, (3) having at least 1 child aged 2 to 5 years, (4) residing in Massachusetts, and (5) having lived in the United States for at least 6 months to ensure sufficient exposure to local health care and cultural systems. This 6-month minimum was required to help ensure participants had adequate time to engage with the US health care system and broader social environment. We aimed to capture insights from parents who had begun navigating pediatric and dental care, encountered potential access barriers, and could reflect on how US-based experiences compared with those in Brazil. Additionally, only 1 parent per household was eligible to participate, ensuring that each interview represented a distinct family unit.

Participants were recruited using purposive sampling, in partnership with local organizations that conducted community-based outreach by distributing study flyers in Portuguese and posting in Brazilian-focused Facebook and WhatsApp groups [33]. Additionally, participants were recruited

XSL•FO
RenderX

using snowball sampling [33]. Interested individuals contacted the research team by text message to confirm eligibility and schedule an interview [33].

Data Collection

Two native speakers with postgraduate training in public health and maternal and child health and extensive experience in qualitative research and engaging with immigrant communities conducted all interviews in Portuguese. One interviewer is a Brazilian immigrant to the United States and a nonpracticing dentist, while the other is a nurse with strong professional ties to the Brazilian community in Massachusetts. Their cultural fluency and professional backgrounds supported a respectful, informed, and empathetic approach to interviewing, contributing to the credibility and depth of the data collected [34].

Interviews were conducted between December 29, 2023, and March 31, 2024. All interviews were conducted via Zoom, a secure video conferencing platform, to ensure participant flexibility and minimize common logistical barriers, such as transportation and childcare. This approach enabled participants to join from a location of their choice, fostering comfort and convenience while maintaining face-to-face interaction, which can increase rapport-building in qualitative research. Before the start of each interview, the interviewer informed participants in Portuguese of the study's purpose, procedures, and their rights, including the voluntary nature of participation and their ability to withdraw at any time without penalty. Verbal informed consent was obtained in Portuguese before proceeding with data collection.

Interviews were conducted using a guide developed based on the SEM and previous research on immigrant health [26,35]. The guide was pilot tested for cultural relevance and clarity. The interview guide was designed to explore three domains: (1) parents' views on the best ways to support their children's oral health, (2) perceived barriers to oral health care, and (3) preferred methods and strategies for addressing barriers and receiving oral health education and care [36-41].

Before each interview, and after obtaining informed consent, participants completed an interviewer-administered sociodemographic questionnaire. The questionnaire, previously validated and used in studies with Brazilian immigrants in the United States, captured key information including age, marital status, educational attainment, annual household income, number of children aged 2 to 5 years, primary language spoken at home, and length of US residency [7]. The interviewer used Qualtrics to access the survey and enter the data.

To assess acculturation, the survey also included the 12-item Short Acculturation Scale for Hispanics (SASH), adapted for Portuguese-speaking populations [42]. The SASH is a validated tool that measures acculturation through 3 subscales: language use, media preferences, and ethnic social relations [42]. Responses are scored on a 5-point Likert scale, with average scores of 2.99 or higher indicating higher levels of acculturation [42,43]. This scale has demonstrated strong reliability across domains (eg, α=.92 overall, .89 for language use, .88 for media preference, and .72 for social relationships) [42,43].

Each interview lasted approximately 40 to 60 minutes and was audio-recorded with the participants' consent. Field notes were also taken to document nonverbal cues, contextual observations, and interviewer reflections [32]. This supplemental information enriched the analytic process and contributed to the rigor of the qualitative approach. Data collection continued until thematic saturation was reached, when no new insights or themes emerged from subsequent interviews [32].

Data Analysis

Transcripts were deidentified to ensure confidentiality and checked for accuracy against the original audio recordings by a bilingual member of the research team. A thematic analysis approach was used to identify and interpret patterns within the data [44]. This method was selected for its flexibility and ability to capture both manifest (explicit) and latent (underlying) meanings in participants' narratives [44,45].

The analytic process began with repeated readings of the transcripts to allow for immersion in the data and develop a holistic understanding of participants' experiences [32,44,45]. A preliminary codebook was developed using a hybrid approach, which incorporated deductive codes informed by the study's theoretical framework (SEM) alongside inductive codes that emerged directly from participants' responses [26,32,44,45]. This approach allowed the team to remain theoretically grounded and open to new or unexpected insights.

Two bilingual researchers independently coded the transcripts line by line using MAXQDA qualitative analysis software (VERBI Software GmbH), which facilitated the application, retrieval, and organization of codes [46]. Coding was conducted in Portuguese to preserve cultural nuance and linguistic fidelity. Following initial coding, the researchers met regularly to compare coding decisions, discuss discrepancies, and refine the codebook through consensus [32,44,45]. Throughout the analysis, the team used a constant comparison method, revisiting previously coded transcripts in light of emerging data to ensure consistency and depth [44,45]. Codes were grouped into broader categories and synthesized into overarching themes that captured the core elements of participants' perspectives and lived experiences. Analytic memos were written throughout the process to document decision-making, emerging insights, and the evolution of thematic interpretations [44,45]. After identifying the themes, we examined them for differences based on family income, acculturation level (measured by length of stay in the United States), and gender.

To enhance the trustworthiness of the findings, we used several validation strategies [44,45]. These included the use of dual independent coders, regular consensus meetings to resolve discrepancies, and ongoing analytic memo writing to reflect on interpretations and researcher positionality. Although we did not conduct member checking or formal data triangulation, the analysis was further strengthened by the constant comparative approach and by the cultural and linguistic concordance between the researchers and participants, which supported nuanced interpretation and contextual sensitivity.

Selected quotes were translated into English for reporting purposes. To ensure linguistic and cultural accuracy, a

XSL•FO
RenderX

back-translation process was used: a second independent bilingual researcher translated the English quotes back into Portuguese, and any discrepancies were reviewed and resolved by consensus. This process helped preserve the original meaning and cultural nuances of participants' statements.

Sociodemographic data were summarized using descriptive statistics, including means, standard deviations, frequencies, and percentages. These analyses were conducted using SAS version 9.4 [47].

Ethical Considerations

This study was approved by the University of Massachusetts Boston Institutional Review Board (IRB protocol number 3541, approved June 26, 2023). All participants provided informed verbal consent. The data were stored securely and accessed only by the research team. Participant confidentiality and the right to withdraw without penalty were emphasized throughout the study. Participants received a US $40 gift card in appreciation of their time and contribution to the study.

Results

Sociodemographic Characteristics of the Sample

In total, 48 Brazilian immigrant parents (29 mothers and 19 fathers) participated in the study. As seen in Table 1, the participants' mean age was 36.5 years (SD 6.6 years), with fathers being older on average (39.1, SD 6.8 years) than mothers (33.9, SD 6.5 years). Most (n=28, 58.3%) participants identified as mixed race, followed by White (n=15, 31.3%) and Black (n=5, 10.4%).

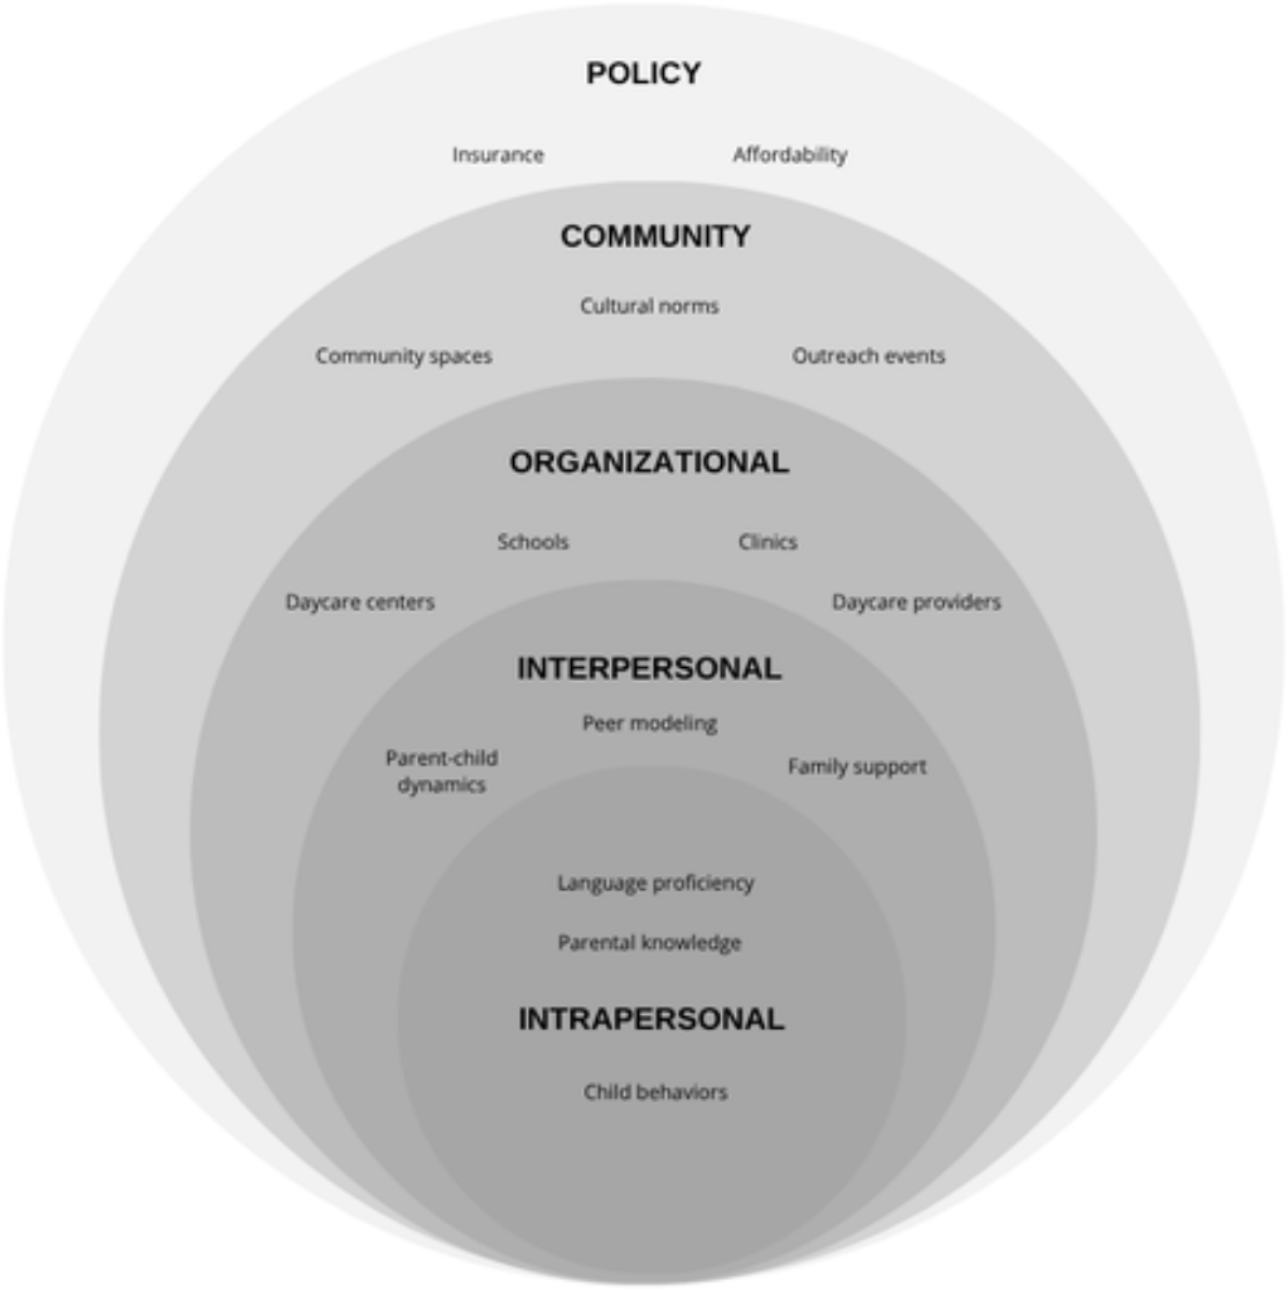
[a]SASH: Short Acculturation Scale for Hispanics.

The majority (n=41, 85.4%) of the participants was married or living with a partner. All participants were born in Brazil, with 58.2% (n=28) originating from the state of Minas Gerais. Over half (n=27, 56.3%) had lived in the United States for less than 5 years. Portuguese was the primary language spoken at home, and 97.9% (n=47) scored below 2.99 on the SASH scale, indicating low acculturation to the United States.

Educational attainment varied among participants, with 79.2% (n=38) having completed high school or more. About half reported an annual household income between US $45,000 and US $65,000 (n=25, 52.1%). Most parents (n=34, 70.8%) had one child aged 2 to 5 years, while 29.2% (n=14) had 2 children in that age range. The majority of participants (n=44, 91.7%) was enrolled in public or government-sponsored health insurance programs, and 68.7% (n=33) reported having dental insurance.



Themes

Overview

The analysis revealed a range of factors influencing Brazilian immigrant parents' perspectives on early childhood oral health. These findings are organized according to the SEM. A conceptual model (Figure 1) visually depicts the SEM levels along with the key themes and subthemes that emerged from the analysis. Representative quotes from parents are integrated throughout the text to illustrate the identified themes and highlight the diversity of perspectives. Notably, gender-based differences were observed in some thematic areas: fathers more frequently emphasized the importance of community outreach and school-based interventions, whereas mothers often focused on home-based education and the challenges associated with navigating health care systems. Differences also emerged by length of time in the United States and income, which further shaped parents' perspectives and experiences.

XSL•FO
RenderX

Figure 1. Social ecological model of influences on Brazilian immigrant parents' perspectives on oral health in early childhood and suggested strategies for education, access, and care.

Intrapersonal Factors: Knowledge Gaps, Language Barriers, and Suggested Solutions for Oral Health

Barriers and Challenges to Children's Oral Health

Parents identified limited knowledge and language obstacles as barriers that they and other Brazilian immigrant families face in supporting their children's oral health. Several noted that caregivers often lack basic information about pediatric dental care. As one mother explained, "There are many mothers who are not educated on how to take care of their kids' teeth. They don't know what's important" (mother #12).

Language barriers were also widely reported, particularly among those newer to the United States. Participants spoke limited English proficiency made it difficult to understand dental recommendations, navigate insurance, or communicate with providers, undermining parents' confidence and ability to advocate for their children. One mother shared, "I'm not fluent in English. It would help to have information in our language" (mother #7). Another parent stressed the need for organizations that support families struggling with language challenges, "There should be places that help families like ours understand things better, especially when we don't speak the language well" (mother #14).

Parents who had lived in the United States for fewer than 5 years more frequently reported these difficulties. This highlights how language barriers and cultural unfamiliarity compounded challenges in accessing timely and appropriate dental care.

Preferred Strategies to Address Barriers

To address key gaps, parents emphasized the importance of parents and children being provided culturally tailored oral

XSL•FO
RenderX

health education especially in Portuguese, when their children are very young to build knowledge and support home-based routines, such as brushing, limiting sugary snacks, and modeling good habits. One mother explained, "Children need encouragement, so that in the future they don't end up spending money fixing dental problems—if they take care of their teeth consistently" (mother #11).

Parents felt that community-based programs were the most likely to be effective. Parents called for "more educational programs" (mother #19), and one father described the need for initiatives "showing the importance of oral health for children and families, and the damage of not taking care of your mouth and teeth" (father #10). These programs were viewed as particularly important for families new (<5 years) to the United States.

Digital and visual learning tools were widely recommended to improve accessibility and engagement. Suggestions included "videos" (father #6), "podcasts" (father #8), "mobile brushing games" (father #14), and "cartoons for children" (mother #18). Mothers generally expressed a stronger preference for visual and interactive materials that they could use together with their children, reflecting their more active roles in day-to-day child care. In contrast, fathers preferred digital formats they could access on their own during commutes or work breaks.

Language remained a significant barrier, particularly for newer immigrants. Participants with lower English proficiency and shorter US residence were more likely to report difficulties related to language and cultural challenges when accessing dental services. Many stressed the need for materials and support in Portuguese to boost their confidence and ability to care for their children's oral health. As one father said, "If I had information in Portuguese, I'd feel more confident taking care of my kids' teeth" (father #9), while another noted, "You trust more when someone speaks your language and understands where you come from" (father #5).

Interpersonal Level: Parent-Child and Social Relationships

Barriers and Challenges to Children's Oral Health

At the interpersonal level, parents described how their relationships with their children, peers, and broader social networks influence oral health behaviors. Key themes included the role of peer modeling and school-based learning in shaping children's habits, the challenges parents face in modeling oral health behaviors due to limited knowledge, and the importance of informal social networks, particularly within immigrant communities, for sharing information and accessing support.

Many parents noted that children learn by observing and often mimic what they see at school or from peers. For example, one mother said, "When this is taught at school, kids come home wanting to do it. When it's only from parents, it doesn't always work" (mother #20). Similarly, a father shared, "Children like to imitate" (father #12), highlighting the strong influence of peer behavior on home routines.

While parents tried to serve as educators, several noted that a lack of oral health knowledge among other adults undermined their ability to model good habits. One mother explained, "... Because there are many mothers who are not educated on how to take care of their kids' teeth. They don't know what's important" (mother #12).

Parents often shared oral health experiences and information within informal community groups. One mother emphasized the role of peer support: "I usually hear about new things from other moms—like which toothpaste is best or when to take my child to the dentist. We really learn from each other" (mother #13). Another highlighted the need for greater connection among parents, stating, "… programs that bring parents together and help us support each other with our children's daily oral health care" (mother #6).

Parents who had recently arrived in the United States and those with lower household incomes or without dental insurance more frequently emphasized the need for accessible, no-cost community resources. For these families, support through free cleanings, oral hygiene kits, and multilingual education was seen not just as helpful but essential. These parents also described a greater reliance on informal community networks, such as churches or local nonprofits, to meet health-related needs, further underscoring the importance of community-based resources.

Preferred Strategies to Address Barriers

To overcome these interpersonal challenges, parents suggested strengthening culturally grounded, community-based programs that engage both families and peer groups. These programs could reinforce positive oral health behaviors by providing education and support within trusted social networks. As one mother expressed, "Programs that support us, helping with our children's daily oral health care" (mother #19), underscoring the importance of accessible, community-rooted resources.

Parents felt that offering no-cost or low-cost services, oral hygiene kits, and multilingual educational materials through informal networks, such as churches and community centers, could improve access and engagement, especially for recent immigrants and lower-income families. As a father noted about trusted community venues, "Churches already bring families together. Adding health workshops there would be very effective" (father #9).

Parents also valued school-based initiatives, seeing them as a way to promote healthy behaviors that children could bring home, helping to bridge gaps in parental knowledge and role modeling. As one mother reflected, "At my daughter's daycare, they brush her teeth after lunch. They asked me if I wanted them to do it" (mother #8), highlighting the power of early education settings in shaping habits.

Organizational Level: Institutions and Services

Barriers and Challenges to Children's Oral Health

At the organizational level, parents highlighted the important role of institutions, such as schools, daycare centers, clinics, and pediatric offices, in shaping children's oral health. However, parents also identified challenges and missed opportunities. Many parents noted missed opportunities in health care settings where oral health promotion and education could be better

XSL•FO
RenderX

integrated. For example, some felt that dental health was overlooked during medical visits. One mother mentioned, "Sometimes when I take my child to the doctor, they only check the general health, and nobody asks about their teeth. It feels like dental health is forgotten" (mother #3). Additionally, unfamiliarity and a lack of culturally welcoming environments made navigating health care systems particularly difficult for immigrant families. One mother expressed, "First is information, for sure, but also being welcomed. That's very important. One of the hardest things when you arrive here is not knowing where to go for help" (mother #10).

Preferred Strategies to Address Barriers

Parents strongly supported embedding oral health promotion within early education settings. They praised daycare programs where children's teeth were brushed after meals, highlighting schools and daycares as critical sites for developing positive habits. For instance, a mother shared, "At my daughter's daycare, they brush her teeth after lunch. They asked me if I wanted them to do it" (mother #8). Others suggested distributing toothbrushes and toothpaste in schools alongside instruction on proper use. One mother stated, "Distribute brushes and toothpaste, and teach children how to use them at school" (mother #5). The influence of peer learning was also emphasized, with 1 parent noting, "When this is taught at school, kids come home wanting to do it" (mother #20).

Despite this enthusiasm, participants noted a lack of oral health programs in local schools. Some reflected on more robust efforts in their home country of Brazil, such as fluoride days and school visits from dentists. As 1 mother recalled, "In Brazil, we had a fluoride day and dentists visiting schools. Here, there's nothing like that" (mother #9). Parents reiterated the value of school-based efforts not only for education but also for motivating children through peer influence.

Regarding health care environments, parents recommended integrating oral health education into routine pediatric visits and offering workshops at clinics. One mother said, "Offer workshops at the same place where children are seen by doctors. Teach mothers how to prevent diseases too" (mother #12). Continuity of care and easier access to multiple clinics were also viewed as important, with parents advocating for follow-ups similar to pediatric care and more options for dental services.

Welcoming environments were especially valued. Parents appreciated when providers gave tangible tools, such as toothbrushes and toothpaste, helping children get excited about brushing. One mother reflected, "First is information, for sure, but also being welcomed. That's very important. One of the hardest things when you arrive here is not knowing where to go for help" (mother #10). Another added, "The dentist gave my son a toothbrush and toothpaste. He came home super excited to brush" (mother 23). Relational and culturally sensitive care settings were seen as essential for building trust and encouraging ongoing engagement.

Community Level: Local Environments and Cultural Context

Barriers and Challenges to Children's Oral Health

At the community level, parents identified environmental, cultural, and informational barriers that limited their ability to support their children's oral health. These included a lack of localized services, culturally appropriate education, and outreach in trusted spaces. Recent immigrants particularly noted difficulties finding oral health resources in their language or in places they frequented. One mother recommended, "A program that goes into the communities, offering free help. Not everyone has health care or dental insurance" (mother #15). Another parent emphasized the need for local programs: "A more accessible program so that children can get cleanings for free. Some kids don't even have MassHealth and can't afford cleanings" (father #7).

Preferred Strategies to Address Barriers

Parents were enthusiastic about community-based outreach efforts that could bring oral health education and services into familiar and trusted environments. Health fairs, free hygiene kits, and toothbrushing demonstrations were widely supported. "Health fairs with free kits and toothbrushing demonstrations would really help" (father #6). "The only thing that could help would be providing us with oral hygiene products" (father #3).

Trusted local institutions, such as churches and community centers, were viewed as effective platforms for education and engagement. A mother explained, "Mothers are usually responsible for health in the family. Community centers could offer this support" (mother #11). A father added, "Churches already bring families together. Adding health workshops there would be very effective" (father #9).

Parents also suggested increasing the visibility of oral health messaging through flyers, posters, and small magazines placed in culturally relevant, high-traffic areas, such as supermarkets and bus stops. "Put up posters in places Brazilians go, like supermarkets or bus stops" (father #5). Another noted, "Distribute flyers, posters, small magazines with information about oral health" (father #4).

Particularly for those newer to the United States, culturally and linguistically appropriate messaging and delivery channels were vital. In contrast, parents with longer US residency often preferred institutional sources, such as schools and clinics, for receiving health information, suggesting a need for varied community engagement strategies.

Policy Level: Structural and Systemic Barriers

Barriers and Challenges to Children's Oral Health

At the policy level, parents highlighted structural barriers, particularly related to insurance coverage, service availability, and systemic navigation challenges. Many families described difficulties using public insurance programs, such as MassHealth, due to bureaucratic complexity and long wait times. One mother expressed, "Sometimes you try to make an appointment, and they say, 'There are no slots. Your insurance isn't active. You have to call MassHealth...'" (mother #9).

XSL•FO
RenderX

Another stated, "I never managed to book a dentist for my son through MassHealth. I think there's little support for the Brazilian community ..." (mother #12).

These experiences reflect what many parents described as system-level inaccessibility, referring to barriers that stem not from a lack of individual effort or community-based resources but from the way the health care system is designed and operates. These include complex insurance rules, difficulty finding providers who accept public coverage, long appointment waiting times, and limited language support within insurance and health systems. For many families, these challenges made it difficult to navigate oral health care, even the services that were technically available.

Preferred Strategies to Address Barriers

Parents proposed policy-level changes such as expanding public dental coverage, increasing provider availability, and simplifying the process of booking appointments. For example, one mother suggested, "They should provide more assistance to families, maybe even schedule appointments through the schools" (mother #24), showing support for integrated service delivery.

There were also calls for systemic reforms to improve support for immigrant communities, such as enhanced language access and outreach by state programs. Broader investments in affordable dental services, policy incentives for providers to accept public insurance, and improved transparency around insurance benefits were also suggested to reduce disparities and ensure equitable care. One father stated: "It's hard for families like mine to get good dental care. Sometimes we don't undertsand the forms or what the insurance covers. I wish there were programs in our language and more clinics that take public insurance (MassHealth), so everyone could get the care they need" (father #4).

Discussion

Principal Results

This qualitative study examined Brazilian immigrant parents' perspectives on promoting early childhood oral health in the United States, revealing multilevel influences that shape knowledge, skills, attitudes, and behaviors. To our knowledge, based on available literature, this is the first study focusing specifically on this population. Key themes emerged across all 5 levels of the SEM, providing a comprehensive framework to understand how individual behaviors are embedded within broader social and structural contexts. This alignment underscores the need for tailored, multilevel interventions to advance oral health equity among Brazilian immigrant families.

At the intrapersonal level, participants emphasized the critical role of their knowledge and skills in shaping oral health behaviors, highlighting the importance of culturally and linguistically tailored education delivered in Portuguese. Consistent with prior research, parents viewed early education for both children and caregivers as foundational for establishing positive oral hygiene habits [30,48-51]. Digital tools, such as videos, apps, and podcasts, were recommended to complement traditional education and accommodate diverse learning preferences and schedules.

Language proficiency emerged as a key intrapersonal and interpersonal factor influencing parents' confidence and self-efficacy in navigating oral health care. Limited English skills hindered comprehension and agency, especially among newer immigrants and those with low acculturation, as previous research demonstrates, underscoring the need for linguistically accessible materials and communication [8-12,22].

At the interpersonal level, parents reflected on family dynamics and peer influence. They acknowledged their critical role as educators and role models for their children's oral health behaviors but also reported knowledge gaps that could limit their effectiveness. Consistent with prior studies, parents noted that children's peer interactions and school-based learning reinforced positive habits, illustrating how family and social relationships work together to shape behaviors [52-55].

Informal social networks within the Brazilian immigrant community also served as valuable sources of support and information exchange for parents, particularly those recently arrived and with limited access to formal resources. Gendered caregiving roles influenced interpersonal interactions, with mothers often assuming primary responsibility for navigating health care, while fathers focused more on structural access issues. Mothers described needing providers who were patient and approachable due to their caregiving role, highlighting how interpersonal dynamics shape emotional components of provider-patient interactions.

Parents identified schools, daycare centers, clinics, and pediatric offices as key organizational settings for oral health promotion. They advocated integrating oral health education and preventive services into early childhood education environments, emphasizing these institutions' unique potential to consistently reach children and families. These findings are supported by prior research [52,53,56-59]. Clinics and pediatric providers were viewed as being underutilized and where relational, culturally sensitive care and consistent follow-up could enhance engagement and outcomes.

Participants emphasized the importance of culturally concordant care and bilingual staff, a finding that aligns with previous research highlighting how such practices strengthen patient-provider relationships and improve communication in institutional settings [60-66]. Organizational efforts to recruit Portuguese-speaking staff and create welcoming environments were seen as essential for overcoming barriers related to trust.

At the community level, participants identified trusted venues, such as churches, community centers, ethnic markets, and local events, as vital platforms for oral health outreach. Consistent with prior research, these settings leverage social capital and cultural resonance, fostering engagement and trust beyond formal health care systems [56-59,67-71]. Parents emphasized the importance of providing free or low-cost services and hygiene products within these community spaces, particularly for lower-income families and those without insurance. Participants also suggested combining in-person community initiatives with culturally tailored digital outreach embedded in familiar networks (eg, WhatsApp groups, church social media pages), enhancing accessibility and sustaining engagement across multiple community touchpoints.

XSL•FO
RenderX

At the policy level, systemic challenges, including insurance complexities, cost barriers, and provider shortages, were viewed as major impediments to timely oral health care. Prior research shows that these structural issues disproportionately affect low-income families and recent immigrants, compounding individual and interpersonal challenges [19,21,22]. Parents called for expanded public dental coverage (eg, MassHealth), policy reforms to increase provider availability, and funding for community-based preventive services, such as oral health kits and mobile clinics. The need for bilingual, culturally competent providers and office staff and navigation assistance reflects policy imperatives to address disparities holistically [28,29,36,72].

Implications for Practice and Policy

The findings emphasize the necessity of coordinated multilevel strategies to effectively promote oral health among Brazilian immigrant families. Practical recommendations include the following:

- Intrapersonal: Deliver linguistically accessible, culturally tailored oral health education and digital resources to improve knowledge and self-efficacy, especially among recent immigrants and those with limited English proficiency
- Interpersonal: Support parental modeling and strengthen peer and family networks as channels for health promotion, while considering gendered caregiving roles and the different relational expectations of mothers and fathers
- Organizational: Integrate oral health into schools, daycare, and pediatric care settings, ensuring culturally competent providers and bilingual staff are available to foster trust and continuity of care. Utilize translation technologies where appropriate
- Community: Leverage trusted community spaces and organizations for outreach, offering free or low-cost services and distributing culturally relevant materials with attention to accessibility for low-income and uninsured families
- Policy: Advocate for expanded dental insurance coverage, increased provider availability, funding for culturally tailored preventive programs, and system navigation supports, such as bilingual oral health navigators and onboarding workshops to assist recent immigrant families.

Special attention is warranted for recent immigrants and economically vulnerable families, which face compounded barriers across all SEM levels. Tailored outreach, considering gendered caregiving roles and flexible service delivery options, such as evening or weekend hours and bundled visits, can improve accessibility and engagement.

Building on these findings, future research should prioritize developing, implementing, and evaluating culturally and linguistically tailored oral health interventions specifically designed for Brazilian immigrant families. Studies could use mixed methods approaches to assess intervention efficacy on behavioral and clinical oral health outcomes over time. Additionally, exploring the role of technology-based solutions, such as mobile health apps and tele-dentistry, may offer scalable ways to overcome language and access barriers.

Further research is also needed to examine intragroup differences by factors such as gender, acculturation level, immigration status, and socioeconomic position to better tailor interventions and policies. Longitudinal studies tracking families' oral health trajectories as they acculturate could provide valuable insights into how social determinants evolve and impact health outcomes.

At the policy level, advocacy efforts should focus on systematic evaluations of insurance programs and community dental services to identify gaps and inform equitable resource allocation. Implementation science frameworks could guide the translation of culturally competent practices into routine care within community health centers and pediatric clinics serving diverse immigrant populations.

Limitations

While this study provides rich qualitative insights, several limitations should be acknowledged. The sample consisted of Brazilian parents residing in a specific US state, which may limit generalizability to other geographic areas or immigrant communities [32]. Additionally, the perspectives of those facing the most significant barriers (eg, undocumented parents) may be underrepresented [33,36,72]. Most participants had dental insurance, which might not reflect the experiences of uninsured families. Despite these limitations, this study offers unique and novel insights into the oral health perspectives of Brazilian immigrant parents, a population that has been understudied in this context. Future research could expand to include more diverse immigrant populations and investigate the implementation and effectiveness of the interventions proposed here.

Conclusions

Brazilian immigrant parents in this study expressed a strong need for linguistically and culturally tailored strategies to support early childhood oral health. Interventions that combine education, improved access to care, and delivery through trusted community settings (eg, daycares, preschools, schools, and churches) offer a promising path to reducing disparities. Parents also emphasized the value of digital platforms, including social media, messaging apps, and online content, as accessible tools for reinforcing oral health messages. Integrating these digital approaches with in-person outreach can improve both reach and cultural relevance. Newly arrived families and those with low acculturation may require additional support in navigating the US dental system, underscoring the importance of onboarding programs and culturally concordant patient navigators. Mothers, often the primary caregivers, face unique logistical and emotional challenges that should inform the design of flexible, family-centered interventions. Policy efforts should focus on expanding access to bilingual, culturally competent providers and investing in both digital and community-based infrastructure to eliminate persistent structural barriers.

Abstract

Background: Parents, as the most proximal influence on young children, play an important role in shaping toddler behaviors. Yet, evidence on how parents shape toddler screen use is limited. Little is also known about the relationship between toddler screen use and BMI. Given existing disparities in screen use and early childhood obesity, a focus on Mexican American families with toddlers is warranted.

Objective: This study aimed to evaluate the independent contributions of both maternal screen use and screen-related parenting practices with toddler screen use duration, for both TV viewing and mobile device use, and examine the relationship between toddler screen use duration and BMI.

Methods: This cross-sectional study enrolled 384 Mexican American mother-toddler dyads recruited from safety net clinics. Enrolled mothers completed 7-day screen use diaries and surveys on screen-related parenting practices, and toddler anthropometrics were obtained. Negative binomial regression models estimated the relationships between screen-related parenting practices and maternal screen use (predictors) with child duration of daily TV use and mobile device use (outcomes). Spearman correlations were calculated to estimate the relationship between toddler screen use duration and age- and sex-specific BMI *z* scores.

Results: Maternal duration of daily TV and mobile device use were associated with toddler duration of daily TV (adjusted rate ratios [aRRs] 1.27 - 1.28; all *P*<.001) and mobile device use (aRRs 1.17 - 1.18; all *P*<.001), respectively, even after adjusting for maternal screen-related parenting practices. Specific parenting practices, including restriction of TV time (aRR=0.86; *P*=.01), restriction of mobile device time (aRR=0.80; *P*=.02), use of TV (aRR=1.27; *P*=.003) and mobile devices (aRR=1.78; *P*<.001) for child behavior regulation, and coviewing of mobile devices (aRR=1.51; *P*<.001), were associated with toddler duration of daily screen use, adjusted for maternal duration of daily screen use. Neither toddler duration of daily TV viewing nor daily mobile device use was correlated with toddler BMI *z* scores.

Conclusions: Both the duration of maternal screen use and screen-related parenting practices, for both TV and mobile devices, should be considered when promoting healthy screen use in toddlers in Mexican American families. Interventionists should consider the family ecology when designing interventions promoting healthy screen use in early childhood.

Introduction

While the American Academy of Pediatrics (AAP) and numerous other organizations have clearly outlined recommended parameters for screen use in children aged younger than 3 years [1-3], effective interventions promoting healthy screen use, such as limited duration of use and no use before bedtime, are lacking for this age group [1,4,5]. This is in part due to the limited evidence informing the design of such interventions [1,4,6,7]. Our understanding of the contributors to screen use in toddlers is lacking, even though screen use often starts in the first year of life, with early screen use behaviors often persisting throughout childhood [8,9]. Given the impact of screen use on the well-being of young children, both positive and negative, there is a need to identify modifiable factors contributing to screen use in the first few years of life [10-12].

Numerous experts have called for a focus on the family ecology around screen media use, particularly in early childhood [10,13-16]. Family systems theory [17], which recognizes the interconnectedness and interdependence of family members and the emergence of behavior patterns within a family system, further suggests the need to evaluate the relationship of screen-related parental behaviors with child screen use. Parents, as the most proximal influence on young children, play an important role in shaping their toddlers' screen use [18]. Evidence suggests that certain screen-related parenting practices (eg, restriction of use or coviewing) are associated with child screen use duration [16,19-22]. In our own previous work with Mexican American families with preschoolers, maternal restriction of duration of TV viewing was associated with fewer minutes of preschooler daily TV viewing [23]. A small study in Canada of mainly White and middle-class families with 1.5- to 5-year-olds as well as a larger study in Israel of parents of toddlers (aged 1.5 - 3 y) reported that greater maternal use of screens to manage child behaviors was associated with increased screen use duration [21,24]. While screen-related parenting practices are important, parents' own screen use, specifically the duration of their screen use, is also associated with child screen use in children younger than 5 years [25-28]. Given the interconnectedness of members within families, children may learn to use screen devices by observing parental behaviors. Moreover, in households with limited space, children may end up watching TV as a natural result of their parents deciding to watch TV themselves. Altogether, these studies suggest multiple ways in which parents shape child screen use behaviors.

Although the evidence on the influence of parent screen-related behaviors on toddler screen use is growing, important limitations of existing research need to be addressed. To start, most of these studies are limited by imprecise measurement of parent and child screen use, using global parental reports to measure screen use, which are not highly correlated with actual screen use [29-31]. Additionally, most studies use 1- or 2-item measures of screen-related parenting, which tend to have poor reliability, and for which validation studies are lacking [21,24,32]. Moreover, only 1 study, to our knowledge, has evaluated the independent associations of parental screen use and screen-related parenting practices with the duration of toddler screen use, finding that both independently predicted child screen time [33]. Parental restriction of screen time was associated with reduced toddler screen time, and parent screen time was associated with increased toddler screen time [33]. Work is needed to clarify whether interventions promoting healthy screen use in toddlers should focus on parents' own screen use in addition to the typical focus on screen-related parenting practices. Addressing these measurement and design issues is important to ensure that future interventions can be designed to focus on modifying the most important influences on toddler screen use.

An additional limitation of existing research is that most studies elucidating the role of parents in shaping screen use in toddlers measure all types of screen use as a single category, even though toddlers interact with multiple different types of screens, including television, smartphones, and tablets [34]. As a result, investigators have been unable to consider whether relationships between parental screen-related behaviors and child screen use vary by screen device type. In our previous work, we found that parental perceptions of the risks and benefits of screen devices can depend on the type of device, which may impact how they parent regarding that device [35]. For example, some parents reported that they needed to pay closer attention to the content their child views on a mobile device compared to TV, and they more commonly used mobile devices for child behavior management than TV [35]. Moving forward, measurement of screen-related parenting should consider variation in parenting across certain screen types to ensure a more nuanced understanding of parenting.

While evidence is growing regarding the impact of screen use on toddler well-being, to date, little is known about whether toddler screen use is associated with BMI [36]. Possible mechanisms for this relationship include increased sedentary time secondary to limited movement while viewing; altered dietary intake, either because screen use while eating distracts one from recognizing satiety cues or screen content (eg, food and beverage commercials) influences food preferences; and reduced sleep duration, potentially resulting from stimulation caused by screen use before bed [36,37]. In children aged 3 years and older, more screen time is associated with obesity [37]. Yet, for children aged younger than 3 years, only a handful of studies exist. Overall, findings are mixed for the studies evaluating the association of toddler screen use with BMI during the toddler years [38-42]. Longitudinal studies, however, suggest that toddler screen use duration does predict BMI years later [43-46]. Yet, again, most of these studies rely on imprecise measurement of screen use (usually a few survey questions). While obesity is multifactorial in origin, understanding the relationship between toddler screen use and toddler weight is needed to inform interventions aiming to prevent early childhood obesity [47].

Focusing future work on Latino children is important because, as a group, they are disproportionately affected by obesity starting in very early life [48-51]. Evidence suggests that approximately 15% of children younger than 2 years and approximately 16% of Latino children aged 2 to 5 years meet the criteria for obesity [48,52]. Unhealthy screen use (eg, higher duration of use) is also more common in low-income Latino children than higher income and non-Latino White children

XSL•FO
RenderX

[53,54]. Recognizing the cultural heterogeneity of Latino populations [55,56], our work focuses on the largest subgroup of Latinos, Mexican Americans [48-51,57,58]. Approximately 16% of children in the United States are of Mexican heritage. Results of this work may therefore be generalizable to a large portion of children in the United States [59,60].

In this study, we aimed to advance our understanding of family-level contributors (ie, maternal screen use and screen-related parenting practices) to toddler screen use in Mexican American families by addressing the above-outlined limitations in the existing literature. We addressed limitations in the measurement of screen use in previous studies by using diaries to measure screen use duration. Screen use diaries are known to be highly correlated with actual screen use and allow measurement of screen use across device types [30,61]. We also used multi-item measures of screen-related parenting practices that we developed through a systematic process, applying a mixed methods approach and allowing for measurement of device-specific parenting [62]. We expected that maternal screen use and screen-related parenting practices would be independently associated with toddler screen use duration, for both TV viewing and mobile device use. Additionally, we examined the association between toddler screen use duration and BMI to expand existing evidence on this topic in toddlers. Findings will help to inform the design of interventions promoting healthy screen use in Mexican American families with toddlers.

Methods

Ethical Considerations

This study was part of a larger cross-sectional study aiming to evaluate contributors to and outcomes of early childhood screen use in Mexican American communities. The Colorado Multiple Institutional Review Board approved this study (18‐1662; initial approval 2018). All participants gave informed consent, documented with an electronic or written signature, before enrolling in the study. Data are stored securely to ensure confidentiality. Participants were compensated with gift cards: US $95 (mother) and US $45 (toddler).

Recruitment

A convenience sample of 384 families was recruited from a safety-net health care system in Denver, Colorado (November 2020 to December 2023). Spanish- and English-speaking parents of toddlers identified as Latino or Spanish-speaking in the electronic medical record and living in the greater Denver, Colorado, metropolitan area were sent an introductory letter about the study. Letters were followed by phone calls with the child's mother (inclusive of caregivers in maternal roles) to assess interest and eligibility. Mothers were eligible if they were at least 18 years old, identified as being of Mexican heritage, had screen devices at home, and denied having a condition that limited the way they used screen devices. Additionally, their 15‐ to 26-month-old child had to be ambulatory, live with them most of the time, and not have a health or developmental condition that impacted their child's sleep, physical activity, diet, or growth. Adult participants in this study are labeled "mothers" since 383 (99%) of 384 were the focal child's birth mother. Of the 773 eligible mothers, 384 (49.7%) completed data collection in this study.

Procedures

Informed consent was conducted by phone by trained bilingual and bicultural team members. Consent documents were sent electronically via text or email based on participant preference, with participant signatures being captured electronically, or in some instances, in person. Following informed consent, mothers completed a 1- to 1.5-hour phone interview in which trained bilingual and bicultural study staff administered surveys. In the days following the first survey, staff dropped off and trained mothers on the completion of the 7-day screen use diary and conducted anthropometric measurements on toddlers. Following the pick-up of the diary, staff administered another 1‐ to 1.5-hour phone interview to complete the final survey items. Survey and anthropometric data were collected and managed using REDCap (Research Electronic Data Capture) tools hosted at the University of Colorado [63]. All communication was conducted in the preferred language of the participant.

Survey items were evaluated and adapted as needed to ensure relevance and clarity for the enrolled sample. Survey items were translated by a bilingual/bicultural team member into Spanish or English as needed. We compared the 2 language versions side by side as a group consisting of bilingual investigators and research staff. We evaluated translations for conceptual equivalence and contextual and cultural relevance, applying a decentering process in which alterations were made to either language version to obtain conceptual equivalence [64,65]. We then pretested items using cognitive interviews in both Spanish and English to ensure easy comprehension as well as shared conceptual meaning across participants and the investigative team [66]. Details of this process are described elsewhere [62,67]. Finally, following in-depth training of the research team, we piloted study procedures with 7 mother-toddler dyads, prior to starting data collection.

Measures

Outcomes

Toddler Duration of Daily TV and Mobile Device Use

Mothers completed a written 7-day daily screen use diary tracking their toddler's TV and mobile device use (smartphones and tablets) in 15-minute increments from 5 AM to midnight, similar to other studies [61,68]. Daily TV and mobile device use amounts in minutes were calculated and then averaged over the number of diary days for those submitting at least 5 days of diary data. Screen use diaries are highly correlated (r=0.84) with the actual amount viewed [30,61], overcoming the limitations of most screen use research that was based on parent global estimates of screen use. Because screen use can change day to day, mothers were asked to complete a full 7-day diary.

Toddler Age- and Sex-Specific BMI *Z* Score

Trained staff measured length in children younger than 24 months or height for those 24 months or older to the nearest 0.1 cm and weight (light clothing and no shoes) to the nearest 0.01 kg, according to recommendations, using portable digital scales (Seca 354) and measuring boards (Seca 417) or stadiometers

XSL•FO
RenderX

(Seca 217) [69]. When it was not feasible to obtain a length in those younger than 24 months or a height in those 24 months or older, we obtained the other measurement, that is, a height or length, respectively, and added or subtracted the standard 0.7 cm [69]. Age- and sex-specific BMI *z* scores were calculated based on the World Health Organization growth charts [70]. BMI is a typical measure of weight status in research studies on this age group [71-75]. Toddler BMI is associated with both adiposity and risk of future obesity [71-75]. Due to COVID-19 pandemic–related restrictions, some toddlers' anthropometrics were not collected or were collected more than 30 days following completion of the surveys and diaries. For this study, toddlers whose anthropometric data were collected more than 30 days from the date of the first survey were excluded from analyses.

Predictors: Maternal Screen-Related Behaviors

Maternal Duration of Daily TV and Mobile Device Use

Mothers completed a written 7-day daily screen use diary tracking their own TV and mobile device use (smartphones and tablets) in 15-minute increments from 5 AM to midnight. Daily TV and mobile device use amounts were calculated and then averaged over the number of diary days for those submitting at least 5 days of diary data. Mothers completed their own screen use diary the same week they completed their child's diary to capture contemporaneous patterns of mother and child screen use. To minimize the possibility of inflated associations, the diaries were designed with separate pages for mother and child and physically bound together in a way that prevented easy side-by-side comparison during completion.

Maternal Screen-Related Parenting Practices

Seven domains of screen-related parenting practices were measured; restriction of toddler screen time (TV use: 8 items, α=.82; mobile device use: 8 items, α=.84), use of screens for behavioral regulation (eg, have their child use a screen to calm down or when misbehaving, TV use: 12 items, α=.90; mobile device use: 16 items, α=.91), coviewing screens with the child (TV use: 10 items, α=.86; mobile device use: 10 items, α=.87), and restriction of content viewed on screens, with screens defined as both TV and mobile devices (8 items, α=.83). Device-related parenting behaviors were not administered to participants who said the focal child had never used the device type (TV or mobile devices), because for these children, no device-specific parenting behaviors occurred. Item response options ranged from never (0) to always (4) on a 5-point Likert scale, with higher values indicating greater endorsement of the item (ie, greater content restriction, greater coviewing). Methods for the development of these measures are described in detail elsewhere [62]. Briefly, items were developed from findings from 32 semistructured interviews with Mexican American parents of toddlers aged 15 to 26 months [35,76], followed by exploratory and confirmatory factor analyses using a split sample approach.

Covariates

Mothers reported child age in months, child gender, maternal age, education level, partnership status (ie, married/partnered or not), employment status (yes/no), number of children in the home, and acculturation. Acculturation was measured using the Bidimensional Acculturation Scale for Hispanics: non-Hispanic acculturation scale (12 items; α=.97) [77]. Scores range from 1 to 4, with higher scores reflecting higher levels of acculturation. To capture the possible impact of the COVID-19 pandemic on everyday life throughout the period of data collection, we created a binary variable that reflected whether the Denver County Department of Health had any COVID-19 pandemic–related restrictions in place at the time of data collection, coded as no restrictions in place=1 and any restrictions in place=0.

Analysis

Analyses were completed in SAS Version 9.4 (SAS Institute). From the sample of 384 participants, we removed those mother-child dyads who were missing duration of daily screen use (mothers n=2; child n=8), and those with toddler anthropometrics collected for more than 30 days following survey administration (n=61), resulting in a sample size of 313. In addition, 20% (n=62) of children did not use a mobile device, and thus, parents were not asked the mobile device–specific parenting practices questions. Accordingly, for analyses involving mobile devices, the sample size was 251. Due to the skewness of some variables, Spearman correlations were calculated between covariates, maternal screen-related behaviors, and outcomes to determine bivariate associations among variables. Because the outcome data were counts, negative binomial regression was used to estimate the relationships between maternal screen use and screen-related parenting practices (predictors) with child duration of daily TV use and mobile device use (outcomes). Regression modeling was carried out separately for TV use and mobile screen use. Three different regression models were estimated for each due to the substantial correlations between some parenting practices. All models included maternal screen use duration, with model 1 estimating restriction of time and content, model 2 estimating behavioral regulation, and model 3 estimating coviewing. Maternal restriction of time and content were included in the same model because, although they represent distinct parenting practices, they are complementary strategies widely recommended to promote healthy screen use in young children [1]. Including both practices in the same model enabled us to examine their independent associations with child screen use duration. Covariates associated with either TV or mobile use at $P<.2$ were included in all models. Final results are presented as adjusted rate ratios. Rate ratios greater than 1 indicate increased screen use for every 1 unit increase in the predictor, while rate ratios less than 1 indicate decreased screen use for every 1 unit increase in the predictor. Maternal duration of daily TV and mobile device use were converted to hours for regression modeling to improve the interpretability of the rate ratios.

Results

Mothers were on average 31 (SD 6.0) years old, and the majority were partnered (264/313, 84.3%; Table 1). Toddlers were on average 21.2 (SD 3.0) months old, and nearly half (153/313, 48.6%) were male participants. The majority of surveys were

XSL•FO
RenderX

administered in Spanish (241/313, 77.0%). Toddler average daily TV use was 94.3 (IQR 49.3 - 173.6) minutes, and average daily mobile use was 27.9 (IQR 6.4 - 66.4) minutes. There was no significant correlation between average daily TV use and average daily mobile use (ρ=0.09; *P*=.15).

Table . Characteristics of Mexican American mother–toddler dyads recruited from safety-net clinics.

Characteristic	Values
Child characteristics (n=313)	
Age (mo), mean (SD)	21.2 (3.0)
Male sex, n (%)	152 (48.6)
Maternal characteristics (n=313)	
Age (y), mean (SD)	31.3 (6.0)
Education (y), mean (SD)	11.6 (2.5)
Partnered, n (%)	264 (84.3)
Employed, n (%)	130 (41.5)
Acculturation: non-Hispanic, median (IQR)	2.2 (1.7 to 3.2)
Number of children in home, median (IQR)	3.0 (2.0 to 3.0)
No COVID-19–related restrictions in place, n (%)	259 (82.7)
Toddler screen use	
Duration of daily TV (min; n=313), median (IQR)	94.3 (49.3 to 173.6)
Child ever used a mobile device, (n=313), n (%)	251 (80)
Duration of daily mobile device use (min; n=251), median (IQR)	27.9 (6.4 to 66.4)
Screen-related parenting practices	
Television[a] (n=307), median (IQR)	
Restrict time	2.3 (1.6 to 2.9)
Behavior regulation	0.9 (0.6 to 1.3)
Coview	2.0 (1.4 to 2.5)
Mobile device use[b] (min; n=251), median (IQR)	
Restrict time	2.5 (1.8 to 3.1)
Behavior regulation	0.7 (0.4 to 1.0)
Coview	1.2 (0.9 to 1.7)
Screen use (n=312), median (IQR)	
Content restriction	3.6 (3.2 to 4.0)
Maternal screen use (n=313), median (IQR)	
Duration of daily TV (min)	75.0 (32.1 to 145.7)
Duration of daily mobile device use (min)	145.7 (70.7 to 246.4)
Toddler anthropometrics (n=274), median (IQR)	
BMI *z* score[c]	0.7 (–0.1 to 1.5)

[a]Reported only for children who ever viewed television (n=307).

[b]Reported only for children who have ever used a mobile device (n=251).

[c]Not reported in some due to the impact of COVID-19 on ability to collect or timing of collection (>30 d from survey administration).

Spearman correlations between maternal screen-related behaviors (screen use duration and parenting practices), child screen use duration, child BMI *z* scores, and covariates included in the final regression models are presented in Table 2 for TV viewing and Table 3 for mobile device use. Neither toddler duration of daily TV viewing nor daily mobile device use was correlated with toddler BMI *z* scores. Similarly, average total duration of screen use, inclusive of TV and mobile device use, was not correlated with BMI *z* scores (ρ=0.06; *P*=.30).

Results of the negative binomial regression models estimating the relationships between maternal screen-related behaviors with toddler duration of daily TV use and daily mobile device use are presented in Table 4. In the regression analyses specific to television use, all models included maternal duration of daily TV (h). Model 1 included the restriction of toddler duration of TV use (restrict time) and restriction of content viewed (restrict content). Model 2 included the parenting practice of using TV for toddler behavior regulation (behavioral regulation), and model 3 included coviewing of TV (coview). Similar models were used in the analysis focused on mobile device use, with variables specific to mobile device use. Findings were similar across models for TV use and mobile device use.

Across all models shown in Table 4, maternal duration of daily screen use variables (TV and mobile device use) were associated with toddler duration of daily screen use for both TV and mobile device use, respectively, even after adjusting for maternal

XSL•FO
RenderX

restriction of toddler screen time and restriction of content viewed, use of screen devices for behavioral regulation, and coviewing (Table 4, all *P*<.001).

Parenting practices were also associated with toddler duration of daily screen use, independent of maternal duration of daily screen use. Increased restriction of toddler screen time, for both TV use and mobile device use, was associated with decreased toddler duration of daily screen use (television use—model 1: restrict time *P*=.01 and mobile use—model 1: restrict time *P*=.02 in Table 4), adjusted for both maternal duration of daily screen use and maternal restriction of content viewed on TV or mobile devices. However, restriction of toddler content viewed on TV or mobile devices was not associated with child duration of daily screen use, when adjusted for both maternal duration of daily screen use and maternal restriction of toddler screen time (Table 4; television use—model 1: restrict content *P*=.28 and mobile use—model 1: restrict content *P*=.60). Increased maternal use of screen devices for child behavior regulation was associated with increased toddler duration of daily screen use for both TV use and mobile device use, independent of maternal duration of daily screen use (television use—model 2: behavior regulation *P*<.001 and mobile use—model 2: behavior regulation *P*<.001 in Table 4). Finally, a mother's practice of coviewing TV with their toddler was not associated with toddler duration of daily TV viewing (television use—model 3: coview *P*=.41), whereas mothers' greater coviewing of mobile devices with their toddler was associated with increased toddler duration of daily mobile use (mobile use—model 3: coview *P*<.001). Both models were adjusted for maternal duration of daily screen use.

Table . Negative binomial regression models evaluating relationships between maternal screen-related behaviors and child duration of daily TV use and mobile use (min).

Negative binomial regression models	Adjusted rate ratio (95% CI)	*P* value
Television use		
Model 1		
Maternal duration of daily TV (h)	1.27 (1.21 - 1.33)	<.001
PP[a]: restrict time	0.86 (0.77 - 0.96)	.01
PP: restrict content	1.08 (0.94 - 1.26)	.28
Model 2		
Maternal duration of daily TV (h)	1.27 (1.21 - 1.33)	<.001
PP: behavior regulation	1.27 (1.08 - 1.49)	.003
Model 3		
Maternal duration of daily TV (h)	1.28 (1.22 - 1.35)	<.001

[a]PP: parenting practice.

Discussion

This cross-sectional study evaluated associations between maternal screen-related behaviors and toddler screen use duration across screen types in Mexican American families recruited from safety-net clinics. Both the duration of maternal screen use and screen-related parenting practices were independently associated with the duration of toddler screen use, suggesting that interventionists should consider both domains of parent behavior when promoting healthy screen use

XSL•FO
RenderX

in toddlers. Addressing the lack of evidence on the impact of screen use on toddler well-being, we also evaluated the relationship between toddler screen use duration and toddler BMI but found no relationship between toddler duration of TV viewing or mobile use with BMI. The methods of this study addressed many of the limitations of previous studies. Specifically, we used 7-day diaries to measure parent and toddler screen use duration and used multi-item measures of screen-related parenting practices developed through rigorous methods to reliably measure multiple dimensions of screen-related parenting practices. Given that early screen use behaviors often persist throughout childhood [8,9], interventions that support families, including parents and toddlers, in the healthy use of screen devices are needed.

This study's finding that both maternal screen use and screen-related parenting practices are related to toddler screen use duration extends previous evidence on this topic. Only 1 other study evaluated both parental screen use and screen-related parenting practices in the same model, assessing the independent effect of each on toddler screen use duration [33]. That study focused on parental restriction of toddler duration of screen use and parental limits on electronics in the bedroom in a socioeconomically diverse sample of families with 18-month-olds in Canada. They found that increased parental restriction of toddler duration of screen use and lower parental duration of screen use were associated with lower durations of toddler screen use [33]. However, their findings are limited due to the use of global estimates of parent and child screen use, inclusive of TV, computers, and video games [33]. Additionally, they did not examine differences by screen device type [33]. Numerous other studies have evaluated either parental screen use [26,33,78-80] or parenting practices in relation to toddler screen use duration, reporting findings similar to ours [16,19-22]. Our study extends the evidence on this topic by evaluating both parental practices and parental screen use together, using enhanced measures of screen use, and evaluating parenting practices specific to screen device type. Altogether, the findings underscore the need for interventions to consider ways to address both parental screen use and screen-related parenting practices in mothers in order to support healthy toddler screen use.

A strength of this study is the focus on Mexican Americans, a cultural group experiencing disparities in unhealthy screen use [53,54], as well as childhood obesity [48-51]. We used methods in this study to ensure rigorous and culturally- and contextually-relevant measurement supporting the validity of the findings [35,62]. While our results may apply to other cultural groups, the evidence provided here could inform the development of interventions aiming to promote healthy screen use in toddlers in Mexican American communities, especially those that are under-resourced. To further enhance the design of such interventions, additional research evaluating how the broader context within which families live and how the related stressors they experience might impact screen-related parenting.

An additional strength of this study is the separate consideration, in both our measurement of screen use and our analytic approach, of TV viewing and mobile device use, thus providing a nuanced evaluation of the relationships between parental screen-related behaviors and toddler screen use. The results suggest that maternal role modeling of both TV viewing and mobile device use is associated with duration of toddler TV viewing and mobile device use, respectively, independent of a variety of device-specific parenting practices. As for screen-related parenting practices, findings were similar for both TV and mobile devices for both time restriction and behavioral regulation with devices. Interestingly, coviewing of mobile devices was associated with increased mobile device use, whereas coviewing of TV was not associated with toddler duration of TV viewing. Prior qualitative work in this population suggests that this could be due to high levels of parental concern for inappropriate content exposure on mobile devices, possibly leading to more coviewing of mobile devices [35]. Moreover, it is possible that when parents are using mobile devices, their toddlers are with them more often than when watching TV. Future research should continue to consider differences in screen-related parental behaviors by type of screen device in use.

The AAP's recommendations regarding certain parental screen-related behaviors are supported by our findings. The AAP recommends limiting toddlers' duration of use as well as limiting parental use of screens for behavioral regulation, both of which were associated in our study with decreased screen use duration for both TV and mobile devices. The AAP also recommends coviewing content with children. While our findings support a link between coviewing and child duration of use for mobile devices, but not for TV, there are numerous reasons why parents should coview both TV and mobile device content with their child [1]. Coviewing of content helps parents to ensure that their child is exposed to appropriate content in addition to offering the possibility of scaffolding their child's learning [1]. The AAP also recommends the use of a "Family Media Plan," which includes parents setting guidelines for their own use [1]. Our finding that the duration of maternal media use is positively associated with child duration of use supports the need for this plan. That said, counseling parents on their parenting practices across a variety of domains is common in pediatric offices, whereas addressing the entire family's behaviors is more challenging [81]. Moreover, whether families are receptive to such counseling from their child's provider is unknown. Research is needed to understand the best approaches for promoting healthy screen use within families, especially given the instrumental support screen devices offer parents in managing child behavior [82,83]. Parental use of screens for behavioral regulation of their toddler is common, offering what is perceived by many parents as an effective way to get things done while with their child [35]. Clearly, intervention work must consider the context of families with young children, parent and child needs, as well as the timing of such intervention.

Similar to the handful of other studies in this area, we did not find a relationship between toddler duration of screen use and BMI [41,42]. Our focus on a specific population and our use of diaries to measure screen use extend the current literature in this area. Proposed mechanisms of the relationship between screen use and a child's BMI may not be as applicable in the first few years of life. For example, toddlers (1- and 2-year-olds) may not be as sedentary while using screen devices compared

XSL•FO
RenderX

to older children. Because early screen use is associated with higher BMIs in the preschool years (ages 3 - 5 y) and beyond, intervening on screen use during the first few years of life is still warranted [36].

Limitations of this study warrant mention. To start, this work only focuses on maternal parenting practices despite research highlighting the important role of fathers in managing child screen use [24,35,84]. Second, the cross-sectional design of this study does not provide information on the direction of the relationships we evaluated. Longitudinal data collection would allow for an understanding of the factors contributing to the development of toddler screen use over time. Third, data collection occurred during different phases of COVID-19 restrictions. Other studies captured changes in multiple behaviors, including screen use, during the early stages of the pandemic [85-87]. Accordingly, we adjusted for COVID-19–related restrictions in our models to control for the possibility that COVID-19 affected these relationships. Finally, while the use of diaries for the collection of screen use is an advance over the measures used in current evidence, enhanced measurement is needed. Moreover, while we intentionally asked mothers to complete their own screen use diary during the same week they completed their child's diary to capture the contemporaneous relationship between mother and child screen use, this approach may have inflated the observed associations. As mentioned previously, we designed the diaries in such a way as to minimize this possibility. Of note, other studies using alternative measures of screen use have noted strong correlations between mother and child screen use, suggesting our finding is not solely an artifact of our measurement approach [25-28]. Recognizing the limitations of self-report measures, investigators are working to develop objective measures of screen use that are feasible and acceptable across diverse populations. One such example is the Family Level Assessment of Screen Use in the Home-Television system, which uses face detection and gaze estimation to measure TV viewing in the home [88].

In summary, both the duration of a mother's own screen use and screen-related parenting practices should be considered when promoting healthy screen use in toddlers in Mexican American families. This holds true for both TV viewing and mobile device use. While these findings support the AAP's recommendations for families, additional research is needed to understand the role of fathers and to identify effective ways for providers to support families in following these guidelines. Furthermore, the development of effective evidence-based interventions that are culturally and contextually relevant is needed.

Abstract

Background: Wearable video cameras may offer a feasible approach to assess the contexts of screen use (eg, screen content and co-use) among preschool-aged children.

Objective: The objective of this study was to assess the contexts of screen use among preschool-aged children using wearable video cameras.

Methods: Children aged 2 to 5 years from Melbourne, Australia, wore a video camera for 1 day in the home environment during May 2023. One researcher manually coded video footage second by second; 15% was double coded for reliability. Coding included device type, screen activity, screen content classified using Common Sense Media ratings, streaming service, setting, social interaction, screen multitasking, and concurrent behaviors.

Results: A total of 37,944 seconds (10.5 hours) of video camera footage from 8 children were identified and coded as screen use, equating to 21.8% (37,944/174,290) of total camera wear time (range 0.3%-74.0%). Screen use was predominately characterized by program viewing (n=37,461, 98.7% seconds) on televisions (n=34,192, 90.1% seconds) in the lounge room (n=33,710, 88.8% seconds). Programs scored low for educational value (mean 1.7, SD 1.4 of 5 stars), and approximately one-third (3/9, 33.3%) of programs were classified as appropriate for an age older than that of the children in this sample. Screen multitasking was rare (n=46, 0.1% of seconds), and coviewing occurred in approximately one-third of all screen use (n=11,010, 29%).

Conclusions: Contexts considered beneficial for development (eg, educational and age-appropriate content) were infrequently observed. This suggests that interventions to equip parents with practical strategies to identify genuine educational content and recognize and avoid age-inappropriate content are warranted. However, our small sample size limits generalizability.

KEYWORDS

early childhood; screen time; smartphone; television; tablet

Introduction

Young children are the fastest-growing users of screens [1], with 2025 estimates indicating that, by the age of 6 years, 62% of children own a tablet, and 10% own a smartphone [2]. The widespread availability of screen-based devices has fueled an ever-growing debate regarding their potential impact on preschool-aged children's health and development. As such, guidelines from the World Health Organization and several individual countries focus on setting time limits, recommending that children aged 2 to 5 years have no more than 1 hour of screen time per day [3-5]. There is emerging evidence suggesting that the context in which screen use occurs may alter associations with health and developmental outcomes. For example, an umbrella review of 102 meta-analyses (youth aged 0-18 years) indicated that coviewing (eg, with a parent) and educational screen content were associated with better literacy outcomes [6]. Additionally, results from a meta-analysis of 100 studies (children aged <6 years) indicated that age-inappropriate content was associated with worse psychosocial outcomes, whereas co-use was associated with better cognitive outcomes [7]. As such, in addition to time limits, pediatric societies of the United States, the United Kingdom, and Canada emphasize quality contexts, recommending that parents coview with their children, choose high-quality programming (eg, educational content), and avoid violent content [8-10].

Much of the evidence informing screen guidelines and recommendations is limited by methodological factors [11,12]. Evidence on preschool-aged children's screen use relies largely on parent-reported measures such as questionnaires and time use diaries, which are prone to bias (eg, social desirability and recall bias) [13]. Additionally, these measures typically focus on traditional media (ie, television and computer and video games) while overlooking newer devices (ie, tablets and smartphones) or aggregate total daily screen use [11,12,14]. Such methodology may fail to capture a comprehensive understanding of the nuanced contexts in which preschool-aged

XSL•FO
RenderX

children engage with screens, such as content consumed, screen activity (eg, program viewing and communication), social interaction (ie, coviewing vs solo viewing), and concurrent behaviors (eg, eating and playing). Thus, measures capable of providing a nuanced understanding of the context of screen use among preschool-aged children are needed to better understand impacts on health and development and better inform guidelines. Wearable video cameras may provide a promising solution as they can continuously capture when, where, and how children interact with screens, providing rich contextual information on screen use.

To our knowledge, only 1 study has used wearable *video* cameras to examine screen use, albeit in an older age group [15]. That study recorded 1081 hours of video footage during the 2 hours before sleep among adolescents (N=83; aged 11-14 years) in New Zealand [15]. Results indicated that most participants used smartphones (n=72 participants; 87%) and televisions (n=70 participants; 84%) during the presleep period, but multiscreen use was also common (n=63 participants; 76%) [15]. The most common screen activities that adolescents engaged in before bed were program viewing (n=76 participants; 92%), browsing (n=68 participants; 82%), communication (n=65 participants; 78%), gaming (n=59 participants; 71%), and social media use (n=51 participants; 62%) [15].

Other studies have used wearable *photo* cameras to examine screen use among adolescents in New Zealand (N=108; aged 11-13 years; n=120,708 images) [16] and Australia (N=10; aged 13-17 years; n=71,396 images) [17]. Results from both studies indicated that television was the most used device (42% of screen time; 36% of images), followed by computers (32% of screen time; 32% of images), mobile devices (13% of screen time; 29% of images), and tablets (13% of screen time; 4% of images) [16,17]. The most common screen activity was program viewing (27% of screen time), followed by games (24% of screen time), social activities (eg, social media and SMS text messaging; 8% of screen time), and using the internet (including online shopping and watching videos on YouTube; 7% of screen time) [16]. Thomas et al [17] reported screen activity separately for each device and further classified screen use in terms of content, setting, social interaction, and concurrent behaviors. Televisions were used primarily for gaming (54% of images), whereas smartphones and tablets were mostly used for program viewing (50%-51% of images). Most screen content was classified as recreational (70% of images), was consumed in the living room (58%) or bedroom (30%), and involved limited co-use with adults (3%) or children (2%), and there were few instances of concurrent behaviors (eg, writing using a pen and paper or having a snack or meal; 13% of images) [17].

While those studies offer initial insights into the potential for wearable cameras to capture screen use contexts, several key evidence gaps remain. First, all prior investigations have focused exclusively on adolescents [15-17], which is unlikely to generalize to preschool-aged children. For example, survey data show that preschool-aged children's daily screen use is typically dominated by television viewing, with little engagement in gaming, social media, or video chatting [2]. In contrast, adolescents' screen use is typically more heavily dominated by social media, gaming, using the internet, and video chatting [18]. Second, most (2 out of 3) prior camera studies have considered a limited set of screen use contexts (ie, device type and screen activity) [15,16]. Other contextual factors such as social interaction and screen content are important to explore due to their potential impact on early childhood development [7]. Finally, with the exception of 1, prior studies have relied on wearable photo cameras rather than video-based devices [16,17]. Photo cameras typically capture images at fixed intervals (eg, every 10 seconds), which may result in missed instances of screen use. In contrast, wearable video cameras provide continuous recording, enabling a more comprehensive understanding of children's screen use contexts.

Extending wearable camera research to early childhood offers an opportunity to capture the nuanced environmental and social contexts of screen use, which are difficult to measure using traditional self-report approaches. To address these limitations, this study aimed to explore a broad range of screen use contexts among preschool-aged children using wearable video cameras. The screen use contexts considered included device type, screen activity, screen content, streaming service, setting, social interaction, coviewing partners, multiscreen activity, and concurrent behaviors.

Methods

Ethical Considerations

Ethics approval was obtained from the Deakin University Human Research Ethics Committee (HEAG-H 04_2023). Written informed parental consent and verbal child assent were obtained before data collection. Household members were asked to provide verbal permission. Data were collected during May 2023 and June 2023 and analyzed between April 2025 and June 2025. Data collected are stored on a restricted shared drive at Deakin University, are presented in aggregate form, and no video footage is published, to protect the identity of participants. Participants received an Aus $10 (US $7.08) supermarket voucher per child participating in the study as a token of appreciation for their time and participation.

Study Design

Data for this pilot observational study were drawn from a larger study that aimed to examine children's physical activity and sedentary behavior in home environments using a combination of wearable devices. Participants wore 3 movement sensors (activPAL [PAL Technologies Ltd], ActiGraph GT3X+, and ActiGraph GT9X Link) and a wearable video camera (Vimel ultrahigh-definition body camera; 1296p; 36 MP) during waking hours. While all devices contributed to the broader assessment of children's movement behaviors, this pilot study focused specifically on the screen use data captured via the wearable video cameras.

Participants and Recruitment

Participants included parents and caregivers (hereafter referred to as "parents") and their children aged 2 to 5 years from Melbourne, Victoria, Australia. To be eligible, parents needed to be able to read English and be aged >18 years. Recruitment took place through convenience and snowball sampling, with participants identified through the research team members' (KD,

XSL•FO
RenderX

KDH, and SJJMV) known networks; institute-wide emails; and a public post on the institute Facebook page (October 30, 2024), which was also shared with the research team's networks. Potential participants were emailed a link to the online study recruitment page (via Qualtrics [Qualtrics International Inc]), where they could view and download an information sheet, undergo eligibility screening, and provide consent should they agree to take part in the study. During the consent process, parents were asked to report their children's date of birth; sex; and residential address, including postcode. Socioeconomic status was classified using the Australian Bureau of Statistics Index of Relative Socioeconomic Advantage and Disadvantage, which ranks postcodes in Australia according to neighborhood socioeconomic conditions from 1 (most disadvantaged) to 10 (most advantaged) [19].

Measures

Wearable Video Cameras

Parents were asked to attach a wearable video camera (Vimel ultrahigh-definition body camera; 1296p; 36 MP) to the front of their children's clothing using a clip and a quick-release lanyard for additional safety. The camera had a size of 75 × 57 × 30 mm and a battery life of approximately 8.5 hours, captured a 140-degree field of view, and was set up to record video only (no audio) for privacy reasons. The cameras were posted to parents along with detailed instructions on how to wear, charge, and turn off the camera (eg, when going to the bathroom or getting undressed). Children were asked to wear the camera exclusively in the home environment for a total of 8 to 10 hours, which could be spread over multiple days. Parents were given the opportunity to view (and delete if necessary) video footage before it was viewed by the research team. The research team removed any accidentally captured video data that were considered a breach of privacy (eg, diaper changes). Video data were date- and time-stamped and permanently deleted from the cameras following download and storage on a restricted share drive.

Image Coding

Video footage data for each participant were manually coded (second by second) by a research assistant using a 2-stage manual coding process in Microsoft Excel. First, all video data were coded to identify the activity undertaken (eg, screen based, reading, playing, eating, physical activity, and socializing). Second, video data that were initially coded as screen based were further classified using a comprehensive coding protocol adapted from similar studies [16,17] (Multimedia Appendix 1). Video footage data were coded for device type, screen activity, screen content, streaming service, setting, social interaction, coviewing partners, multiscreen activity, and concurrent behaviors. Screen content was classified using Common Sense Media's ratings for quality (ie, positive messaging, positive role models, violence and scariness [reverse scored], and educational value) and age-appropriateness [20]. Consistent with previous studies [21], each quality indicator was rated on a scale from 0 to 5, where 0 was "not present" or "not applicable," 3 indicated a fair amount of that content, and 5 indicated a lot of that content.

Footage that was "blocked" or had an obscured view was considered inconclusive for determining screen use behavior, especially if the camera angle was directed away from the screen or the footage was blackened due to obstruction. Blocked or obscured footage was partially coded. For example, if a device type was known to be in use but other screen information was blocked, the device type, but no other screen use information, was coded. A subset of the identified screen time video footage (15%) was double coded by the first author (AM).

Data Analyses

Analyses were conducted in Stata (version 18.0; StataCorp LLC). Camera wear time was calculated as the total number of minutes during which video footage was recorded. Descriptive statistics (means and proportions) were used to describe the sample and calculate time spent in each screen use context. Independent-sample 2-tailed *t* tests were performed to examine differences between mothers and fathers in terms of coviewing session duration and total coviewing duration. Interrater reliability for the double-coded footage was calculated using the κ statistic and interpreted as follows: κ=0.00 to 0.20 indicated slight agreement, κ=0.21 to 0.40 indicated fair agreement, κ=0.41 to 0.60 indicated moderate agreement, κ=0.61 to 0.80 indicated substantial agreement, and κ=0.81 to 1.00 indicated almost perfect agreement [22].

Results

Interrater Reliability

Coder agreement was high across most screen use contexts. Perfect reliability was achieved for device type, multiscreen activity, and setting (κ=1.00), whereas screen content (κ=0.95), streaming service (κ=0.94), social interaction (κ=0.87), screen activity (κ=0.84), and coviewing partners (κ=0.82) exhibited very strong agreement. In the initial coding round, the concurrent behavior categories of play and fidgeting were differentiated using time-based criteria, whereby shorter durations were coded as "fidgeting" and longer durations were coded as "playing." However, this interpretation was somewhat subjective, and the coding protocol was subsequently revised to distinguish between "object-based" and "non–object-based" play and fidgeting, which achieved substantial agreement (κ=0.64).

Sample Characteristics

A total of 11 parents of preschool-aged children consented to take part in the study; however, 2 (18.2%) of the participants refused to wear the video camera. The final sample comprised 9 children, who recorded a total of 174,290 seconds (48.4 hours) of video camera footage over the observation period. Mean wear time was 5.4 (SD 2.9; range 0.3-10.1) hours. A total of 37,944 seconds (10.5 hours) of video camera footage from 8 children were coded as screen use, equating to 21.8% (37,944/174,290) of total camera wear time (range 0.3%-74.0%). Children were, on average, aged 3.8 (SD 1.1; range 2-5) years, 2 were girls, and 6 were boys. The child who recorded no screen use in their 0.3 hours (n=1245 seconds) of recording was a girl aged 3 years. Children were predominantly from advantaged backgrounds, with most residing in areas classified within Index of Relative

XSL•FO
RenderX

Socioeconomic Advantage and Disadvantage deciles 8 to 10; 1 child was from an area classified as decile 6.

Device Type, Screen Activity, Setting, and Social Interaction

Table 1 shows the duration of screen use by device type, screen activity, setting, and social interaction. Overall, screen use was quite homogeneous, with program viewing (37,461/37,944, 98.7% of seconds), televisions (34,192/37,944, 90.1% of seconds), and lounge room use (33,710/37,944, 88.8% of seconds) dominating screen activity, device type, and setting, respectively. Program viewing was the sole screen activity when using televisions (34,192/34,192, 100% of seconds) and tablets (2577/2593, 99.4% of seconds). In contrast, screen activity during smartphone use was more heterogeneous, including program viewing (692/1159, 59.7% of seconds), communication (345/1159, 29.8% of seconds), and browsing (122/1159, 10.5% of seconds). However, smartphone use accounted for only 3.1% (1159/37,944) of total screen use. Coviewing occurred in approximately one-third (11,010/37,944, 29% of seconds) of all screen use but differed by device type (television: 8053/34,192, 23.6% of seconds; smartphone: 567/1159, 48.9% of seconds; tablet: 2390/2593, 92.2% of seconds). Concurrent behaviors occurred during 38.6% (14,632/37,944) of screen use time, with eating snacks (5751/37,944, 15.2% of seconds) and non–object-based fidgeting (5847/37,944, 15.4% of seconds) being the most common, and these were relatively consistent across device types.

Table . Duration of screen use by device type, screen activity, setting, and social interaction.

	Smartphone (n=1159 seconds)	Television (n=34,192 seconds)	Tablet (n=2593 seconds)	Total (n=37,944)
Screen activity (seconds), n (%)				
Browsing	122 (10.5)	0 (0.0)	16 (0.6)	138 (0.4)
Communication	345 (29.8)	0 (0.0)	0 (0.0)	345 (0.9)
Program viewing[a]	692 (59.7)	34,192 (100.0)	2577 (99.4)	37,461 (98.7)
Setting (seconds), n (%)

Kitchen	853 (73.6)	0 (0.0)	0 (0.0)	853 (2.2)
Lounge room	234 (20.2)	30,883 (90.3)	2593 (100.0)	33,710 (88.8)
Parents' bedroom	21 (1.8)	1125 (3.3)	0 (0.0)	1146 (3.0)
Playroom	8 (0.7)	2184 (6.4)	0 (0.0)	2192 (5.8)
Social interaction (seconds), n (%)				
Inconclusive	0 (0.0)	756 (2.2)	192 (7.4)	948 (2.5)
Coviewing	567 (48.9)	8053 (23.6)	2390 (92.2)	11,010 (29.0)
None	592 (51.1)	25,383 (74.2)	11 (0.4)	25,986 (68.5)
Concurrent behaviors (seconds), n (%)				
Eating meals	0 (0.0)	357 (1.0)	0 (0.0)	357 (0.9)
Eating snacks	293 (25.3)	5317 (15.6)	141 (5.4)	5751 (15.2)
Fidgeting—non–object-based	66 (5.7)	4686 (13.7)	1085 (41.8)	5847 (15.4)
Fidgeting—object-based	30 (2.6)	1627 (4.8)	109 (4.2)	1767 (4.7)
Playing—non–object-based	0 (0.0)	327 (1.0)	0 (0.0)	327 (0.9)
Playing—object-based	0 (0.0)	585 (1.7)	11 (0.4)	596 (1.6)
None	770 (66.4)	21,293 (62.3)	1247 (48.1)	23,312 (61.4)

[a]Program viewing predominately comprised watching programs and/or movies (35,028/37,461, 93.5% of seconds), but content selection (1034/37,461, 2.8% of seconds), waiting for autoplay (247/37,461, 0.7% of seconds), and loading screen content (27/37,461, 0.1% of seconds) were also categorized as program viewing.

Duration of Coviewing Sessions

A total of 44 coviewing sessions were captured. Among these 44 coviewing sessions, after excluding 3 (6.8%) involving both parents (to avoid double counting), 6 (13.6%) involving another child, and 2 (4.5%) where the coviewing partner could not be determined, there were 19 (43.2%) sessions involving fathers (with or without other family members) and 14 (31.8%) involving mothers (with or without other family members). Coviewing sessions involving fathers lasted, on average, 4.9 (SD 9.2; median 0.85, IQR 0.2-5.0; range 0.1-38.6) minutes, whereas sessions involving mothers lasted, on average, 1.1 (SD

XSL•FO
RenderX

1.2; median 0.75, IQR 0.3-1.5; range 0.2-4.1) minutes; however, this difference was not statistically significant either before (t_{31}=–1.50; P=.14) or after (t_{30}=–1.55; P=.13) removing 1 outlier involving a coviewing session with a father lasting 38.6 minutes.

Coviewing Partners

Approximately one-third (11,010/37,944, 29%) of screen use involved coviewing. Table 2 shows the coviewing partners of preschool-aged children. Approximately two-thirds (7396/11,010, 67.2% of seconds) of coviewing instances involved at least one parent, mostly the father (5558/11,010, 50.5% of seconds) but occasionally both parents (882/11,010, 8% of seconds) or the mother (956/11,010, 8.7% of seconds). Coviewing with an older child was also common (3556/11,010, 32.3% of seconds). After excluding coviewing sessions involving both mothers and fathers to avoid double counting, fathers spent longer coviewing with their children (mean 1111.6, SD 923.07 seconds) compared with mothers (mean 159.33, SD 112.46 seconds), and this difference was statistically significant (t_9=–2.5; P=.03). However, after removing the outlier described above, this difference did not remain significant (coviewing involving fathers: mean 648.4, SD 680.42 seconds; coviewing involving mothers: mean 159.33, SD 112.46 seconds; t_9=–1.75; P=.11).

Table . Coviewing partners (by duration) of preschool-aged children (total duration=11,010 seconds).

Coviewing partner	Duration (seconds), n (%)
Unable to tell	58 (0.5)
Father	4807 (43.7)
Father and mother	882 (8.0)
Father and older child	6 (0.1)
Father and younger child	745 (6.8)
Mother	564 (5.1)
Mother and grandmother	46 (0.4)
Mother and older child	346 (3.4)
Older sibling	3556 (32.3)

Multiscreen Activity

There was very little multiscreen activity (46/37,944, 0.1% of all screen use), with a single recorded instance. This instance occurred for a brief duration (46 seconds) and involved watching sports on television while simultaneously watching a song video on a smartphone.

Streaming Services

Children viewed a range of content across various streaming services, including YouTube Kids (9/20, 45% of programs), Netflix (6/20, 30% of programs), SVT Barn (2/20, 10% of programs), Spotify (1/20, 5% of programs), ABC iview (1/20, 5% of programs), and Foxtel (1/20, 5% of programs). For 8.8% (3345/37,944) of seconds of video footage (6 occurrences involving 3 participants), the streaming service could not be determined due to the screen content being inconclusive.

Content Classifications

Content classifications were available for 45% (9/20) of the programs, representing 61.8% (23,441/37,944) of screen use footage. Programs scored approximately 3.0 out of 5 stars for positive messaging (mean score 3.0, SD 1.00; range 1-4 stars) and positive role models (mean score 3.1, SD 1.17; range 1-5 stars) and approximately 1 star for violence and scariness (mean 1.3, SD 1.22; range 0-3 stars) and educational value (mean 1.7, SD 1.41; range 0-4 stars). Approximately one-third (3/9, 33.3%) of programs were classified as appropriate for an older age than those of the children in this sample (ie, for the ages of ≥6, ≥8, or ≥10 years).

Content Classifications and Social Interaction

Table 3 shows the mean content classification scores for coviewing vs solo viewing. Mean content classification scores differed according to social interaction. Specifically, mean scores were lower for educational value and positive messaging and higher for violence and scariness and positive role models when programs were coviewed than when programs were solo viewed.

Table . Content classification and social interaction of preschool-aged children. Total viewing time was 7171 seconds for coviewing and 15,528 seconds for solo viewing.

Content classification	Coviewing (number of stars), mean (SD)	Solo viewing (number of stars), mean (SD)	*t* test (*df*)	*P* value
Educational value	1.3 (1.2)	2.7 (0.9)	–95.4 (22,697)	<.001
Violence and scariness	2.0 (1.2)	0.9 (0.6)	96.1 (22,697)	<.001
Positive messages	3.2 (0.8)	3.6 (0.5)	–48.6 (22,697)	<.001
Positive role models	3.6 (1.0)	3.22 (0.42)	–37.1 (22,697)	<.001

Discussion

Principal Findings

This study appears to be the first, worldwide, to objectively assess preschool-aged children's free-living screen use contexts using wearable video cameras. Our analysis yielded 4 main findings. First, screen use contexts among preschool-aged children were relatively homogeneous. Second, screen content was generally classified as low in terms of educational value, and one-third of content (3/9, 33.3% programs) was considered age inappropriate. Third, coviewing occurred in approximately one-third of screen use (11,010/37,944, 29%). Fourth, wearable video cameras provided a feasible approach for assessing preschool-aged children's screen use contexts, albeit with some caveats. While a large amount of screen use data were captured (n=37,944 seconds), our findings should be considered alongside limitations associated with our small convenience sample (N=8).

This study showed that screen use contexts among preschool-aged children were relatively homogeneous. In our sample, almost all screen use involved program viewing of streamed or on-demand content on televisions in the lounge room. There was very little smartphone use or engagement in other screen activities such as communication or browsing. While the lack of variability in screen use may reflect our small, homogeneous sample, all from middle to high socioeconomic backgrounds, our focus on screen use in the home environment may have also influenced the results. Greater engagement with mobile devices and a wider range of screen activities might have been observed had we captured screen use outside of the home environment. For example, during interviews in a previous study, mothers (n=26) of preschool-aged children (aged 2-4 years) from the United Kingdom reported that they often allowed their children to use mobile devices outside of the home for a range of screen activities due to their multifunctionality, including playing games and taking and looking at photos, as well as program viewing [23]. Nonetheless, our finding that the television remains the primary source of screen use (34,192/37,944, 90.1%, of screen use in our sample) for preschool-aged children is consistent with results from previous studies [2,24,25] and suggests that older evidence from before the emergence of mobile devices is likely still relevant for this age group.

We found that the programs that preschool-aged children viewed were generally classified as having little educational content, and one-third of the programs (3/9, 33.3%) were classified as age inappropriate according to Common Sense Media ratings. Similarly, previous studies have shown that most content viewed by preschool-aged children is for entertainment rather than educational purposes [24,25]. It is possible that this finding reflects the nature of children's television programs, with a 2019 examination of 88 popular children's television shows in the United States indicating that, overall, shows aimed at children aged 2 to 5 years contained little educational content, scoring a mean of 2.44 out of 5 stars based on Common Sense Media classifications [21]. This is of concern given that substantial evidence demonstrates that high-quality educational television, such as Sesame Street, may benefit children's cognitive, literacy, and social outcomes [26-29] and age-inappropriate content can negatively impact psychosocial outcomes [7]. An alternative explanation for the low educational value of the screen content observed in this study may be that, although screen guidelines from pediatric societies emphasize high-quality programming [8-10], this messaging may not be reaching parents. Thus, interventions aiming to support healthier screen use behaviors in preschool-aged children might focus on equipping parents with practical strategies to identify genuine educational content and recognize and avoid content that may be age inappropriate. Efforts could also involve engaging with industry to formally and scientifically evaluate content before making educational claims [10].

Coviewing in our sample occurred in approximately one-third of screen use (11,010/37,944, 29%). In contrast, Thomas et al [17] reported that just 16% of screen use involved coviewing among adolescents, with <1% involving interactive coviewing (n=7 images involving a laptop computer). However, the authors did not describe how this was coded from the camera images, making it difficult to ascertain how comparable this finding is to our data. In our study, we could not distinguish between interactive coviewing (eg, where another person asks questions or explains content) and passive coviewing (eg, where another person is present but not interacting with the child). This distinction is important as research suggests that interactive rather than passive coviewing can enhance language and cognitive development (eg, attention and memory) [24,30,31]. While the inclusion of audio data alongside video footage could be used to assess the quality of interactions, this approach may present additional ethical and feasibility challenges given the sensitive nature of recording in home environments. Future work may consider the inclusion of ecological momentary assessment to capture interaction during coviewing.

Wearable *video* cameras offer a promising and feasible approach to assessing preschool-aged children's screen use in real-world contexts. Using these devices, we were able to objectively quantify a range of nuanced contextual information on preschool-aged children's screen use. While wearable cameras reduce recall bias and offer a richer, more detailed account of children's interactions with screens compared with self-report measures, several caveats must be considered. The success of this approach relies heavily on both parent consent and children's willingness to wear the device consistently. A total of 11 parents of preschool-aged children consented to take part in this study, and most children (9/11, 81.8%) were willing to wear the device (mean wear time 5.4 hours), indicating that our protocol was feasible. Additionally, establishing strong interrater reliability is essential to ensure the reliability and replicability of the results. Our coding protocol achieved a high level of interrater reliability, supporting the robustness of our findings. Lastly, the substantial volume of video data generated from wearable video cameras makes coding time and labor intensive, underscoring the need to account for these factors in the study planning phase. As such, while wearable video cameras offer valuable insights into preschool-aged children's screen use, their implementation requires careful ethical, practical, and methodological considerations.

XSL•FO
RenderX

There are a number of study limitations that should be acknowledged. While a large amount of screen use data were captured (10.5 hours), the small convenience sample and relatively homogeneous demographic characteristics limit generalizability to the wider preschool population. As such, future studies using larger samples are needed to overcome this limitation. Moreover, video footage data captured screen use exclusively in the home environment. As screen use outside the home environment may yield different patterns, future wearable camera studies examining screen use contexts both inside and outside the home environment are warranted. A previous wearable camera study in adolescents recorded camera footage both inside and outside the home environment, including on public transport, public food outlets, and community venues, suggesting that this approach is feasible and acceptable [17].

Conclusions

Among a small sample, we showed that preschool-aged children's screen use is relatively homogeneous, predominately characterized by program viewing of streamed content on televisions in the lounge room. While there was some positive messaging and role models, the content viewed by children was generally considered of little educational value and at times age inappropriate. Coviewing occurred during approximately one-third of screen use and more often with fathers than mothers. We showed that wearable video cameras offer a feasible and acceptable approach to collect more accurate and detailed data on preschool-aged children's screen use contexts compared with traditional self-report measures. This study provides some useful insights for intervention development. However, being the first study of its kind in this population, further research on preschool-aged children's screen use contexts both inside and outside the home using wearable cameras in larger samples is warranted to confirm our findings.

Acknowledgments

The authors would like to acknowledge Keenan Baker for providing assistance with coding the video camera footage for screen use contexts. The authors would also like to acknowledge the research assistants who initially coded the video camera footage for screen use.

Funding

KDH is supported by a Heart Foundation Future Leader Fellowship (105929). AM and SJJMV are both supported by Deakin University Postdoctoral Research Fellowships.

Data Availability

The datasets generated or analyzed during this study are not publicly available due to privacy reasons as it is not possible to fully deidentify video data due to the nature of the images captured.

Abstract

Background: Responsive feeding is an integral component of nurturing care under the umbrella of early childhood development and has been recommended as an optimal feeding practice globally.

Objective: This study was conducted to explore responsive and nonresponsive feeding practices among caregivers of children aged 6 - 35 months in China. Factors influencing responsive/nonresponsive feeding practices were further explored.

Methods: This study used a combination of survey and video observation approaches and was conducted in Hebei Province from August to October 2020. A cross-sectional survey (n=409) was conducted to measure caregivers' responsive/nonresponsive feeding practices using a prevalidated scale (5-point Likert scale). The overall and individual dimension scores were calculated. Multiple linear regression was performed to explore the demographic factors associated with responsive/nonresponsive feeding practices. Video observation was conducted among 42 caregiver-child pairs to record the dining episodes of main meals for a day at participants' homes. Videos taken were coded, and the feeding practices were extracted. The occurrence of each feeding practice was calculated. The results from the 2 methods were confirmatory and complementary to each other.

Results: Caregivers adopted responsive feeding more frequently than nonresponsive feeding, with a median overall responsive feeding score of 3.52 (IQR 3.36-3.76) in the survey and a higher occurrence in video observation (responsive vs nonresponsive feeding: 75.6% - 97.6% vs 0%-46.3%). No significant differences in feeding practices were found across breakfast, lunch, and dinner (all P>.05). Nonparental caregivers (β=0.13, 95% CI 0.05-0.21) and those with a household monthly income of >5000 RMB (>US $721; β=0.07, 95% CI 0.01-0.14) had a higher score for overall responsive feeding, while unemployed caregivers (β=−0.07, 95% CI −0.13 to −0.01) had a lower score.

Conclusions: Caregivers appear to be more likely to use responsive feeding practices than nonresponsive feeding practices. Interventions to promote responsive feeding should target parental, unemployed, and low-income caregivers. The findings of this study might serve as a reference for the comprehensive assessment of responsive feeding practices.

KEYWORDS

responsive feeding; survey; video observation; infant and toddler; factors

Introduction

Nurturing care is an essential element in the promotion of early childhood development [1]. In 2018, the World Health Organization (WHO) and other international organizations jointly proposed 5 core elements of nurturing care [2]. One of the elements is responsive parenting, which requires caregivers to discern children's needs from their movements, sounds, expressions, and oral requests in daily life, and to provide timely and appropriate responses [3]. Responsive feeding refers to the positive interaction between caregivers and infants during the feeding process, where caregivers provide timely and appropriate responses to signals of hunger and satiety in infants and young children [3]. Responsive feeding has been

XSL•FO
RenderX

incorporated into the infant and young child feeding guidelines by the WHO [4]. On the contrary, nonresponsive feeding should be avoided. As described by our research team, responsive feeding practices include the practices of responsiveness to cues, modeling, active communication and interaction, and creating a good meal environment, while nonresponsive feeding practices include controlling, pressure to eat, the use of food as a reward, and emotional feeding [5,6].

Previous studies about responsive/nonresponsive feeding have mainly been conducted in North America, Europe, and Australia [7,8]. A study in the United States demonstrated that the average frequencies of responsive feeding practices (eg, modeling and reasoning) at breakfast, lunch, and dinner were 9.2, 9.7, and 15.4 times, respectively, while the frequencies of nonresponsive feeding practices (eg, coercive-controlling prompts) at the same points were 2.9, 3.0, and 5.8 times, respectively [7]. A study in Australia revealed that the scores for nonresponsive feeding among caregivers in Australia were relatively low, with a mean score of 1.86 (SD 0.99) for the use of food as a reward and 1.99 (SD 0.64) for emotional feeding among caregivers of 2-year-old children [8]. Moreover, some studies have investigated responsive/nonresponsive feeding in China, with the majority (16/20) conducted in southern China. Chinese studies examined the practices of pressure to eat, the use of food as a reward, and active communication and interaction, while there is a paucity of reports on controlling, responsiveness to cues, modeling, and creating a good meal environment [9].

Responsive/nonresponsive feeding practices are typically assessed by survey or observation methods, each with distinct advantages and limitations. The survey method, which has been adopted by most studies [10], allows for large-scale data collection. However, existing tools used by surveys are unable to cover all dimensions of feeding practices [11]. In the Chinese context, certain practices (eg, controlling and responsiveness to cues) are still underreported [9]. Most observation studies used videos to record the process of feeding [12]. Home is the natural environment where children dine. Thus, taking videos to record the feeding episodes at home is feasible and can reflect real-life feeding practices. However, the observation method is only suitable for studies with a small sample size due to its high cost and respondent burden. Combining survey and observation methods in a single study can obtain rich information and explore the topic in-depth [13-15]. The survey provides quantitative breadth, while the observation yields qualitative depth, and they together offer a holistic understanding of feeding practices. For example, a study in Ethiopia found that when children refused to eat, the coping strategies reported by caregivers in questionnaires included increasing food variety and pressure to eat, and additional strategies were observed in videos, including changing caregivers, communicating with the children, and threatening [13]. In this study, a combination of survey and video observation methods was necessary to gain a comprehensive understanding of responsive/nonresponsive feeding practices and to address the gaps in the Chinese literature.

This study had 3 primary aims. First, we sought to provide a quantitative profile of responsive and nonresponsive feeding practices among caregivers of children aged 6 - 35 months in China. Every dimension of responsive/nonresponsive feeding was examined. Second, we conducted video observation among a small sample, in order to gain an in-depth understanding of feeding interactions. The video observation allowed us to capture subtle, unreported behaviors and contextual details that surveys might miss, thereby complementing the survey data by providing richness and depth. Third, using the survey data, we aimed to identify key demographic factors (eg, caregiver's employment status, education level, family income, etc) associated with these feeding practices to inform future interventions. Consequently, this study would contribute to the literature by (1) providing novel and in-depth data on the responsive/nonresponsive feeding practices of Chinese caregivers; (2) demonstrating the value of a mixed methods approach, using a survey method for breadth and an observation method for depth to achieve a more holistic assessment of feeding practices; and (3) identifying potential targets for responsive feeding interventions in China.

Methods

Design

This study adopted a combined approach, involving a questionnaire survey conducted among a relatively large sample and a video observation study conducted among a relatively small sample. The survey was reported according to the STROBE (Strengthening the Reporting of Observational Studies in Epidemiology) guidelines, and the video observation was reported in adherence to the COREQ (Consolidated Criteria for Reporting Qualitative Research) checklist.

Ethical Considerations

Approval to conduct this study was obtained from the Ethics Committee of Peking University (IRB00001052-20047; approval date: August 1, 2020). This study has been performed in accordance with the ethical standards laid down in the 1964 Declaration of Helsinki and its later amendments. All caregivers signed a written informed consent form before any assessment. Adhering to privacy and confidentiality guidelines, all identifiable participant details, including names, hospital numbers, and recognizable features in images, were anonymized or omitted. Participants of the survey received a small toy valued at 5 RMB (US $0.72), while participants of the video observation received 100 RMB (US $14).

Survey

Study Design

A cross-sectional survey was conducted from August to October 2020 in Shijiazhuang City, Hebei Province, China. Methods for participant selection, recruitment, data collection, and the key instrument have been detailed in our previous publication [5,6].

Participants

Family members who took the primary responsibility of child caregiving were our potential participants. Caregivers were included if they (1) were permanent residents of the study area; (2) had a certain level of literacy; and (3) had a child at full-term delivery, of normal birth weight, and aged 180 days to 3 years (excluding the full age of 3 years). Caregivers were excluded if they had a child with diseases that affect eating (eg, cold,

XSL•FO
RenderX

fever, diarrhea, and food allergies), congenital diseases, infectious diseases, genetic metabolic diseases, deformities, mental diseases (eg, depression), or other serious illnesses (eg, cancer, severe liver or kidney diseases, and AIDS). All included participants signed a written informed consent form before any assessment.

Recruitment and Data Collection

This study was advertised through posters at Loudi Township Hospital of Luancheng District. A convenience sampling method was used to recruit caregivers who visited the hospital for routine health check-ups and vaccinations. Eligible caregivers signed an informed consent form after being informed of the purpose and process of the study. Participants were then required to complete a questionnaire via a face-to-face interview with the researcher, which took approximately 20 minutes. They were given a small toy valued at 5 RMB (US $0.72) as an incentive to participate in this study. Researchers checked each completed questionnaire. Participants who provided missing or illogical answers were further contacted for adjustment. Data entry was finally performed, with 10% double entry for quality assurance.

Questionnaire

A cross-sectional questionnaire was developed to collect participants' general demographic characteristics and their responsive/nonresponsive feeding practices. Caregivers' responsive and nonresponsive feeding practices were measured by a scale, which was based on previous validated scales [16-18] and then further modified by our research team. Details on the construction and validation of this responsive/nonresponsive feeding scale have been provided in our previous publication involving the same study population [5]. In brief, the full Parents' Feeding Practices Scale for Infant and Young Child (PFPSIYC) was adopted to assess 5 feeding dimensions (including controlling, pressure to eat, the use of food as a reward, emotional feeding, and modeling). The PFPSIYC has been used to assess Chinese caregivers of children aged 6 - 23 months, with acceptable reliability and good validity [16]. Some items from the Infant Feeding Style Questionnaire (IFSQ) were used to evaluate caregivers' responses to dietary cues. The IFSQ has been used among caregivers in the United States, with good reliability [17]. Some items were adopted from the Young Child Feeding Questionnaire (YCFQ) to evaluate active communication and interaction between caregivers. The YCFQ has been applied to caregivers of children aged 6 - 18 months in China, with acceptable reliability [18].

To ensure the instrument's suitability for the context of this study, a pilot study was conducted among 132 caregivers in Hebei Province. This pilot study confirmed the feasibility of the survey procedures and the comprehensibility of the items. The pilot study showed acceptable internal consistency (Cronbach α=0.810) and structural validity (cumulative variance explained=61.6%) of the feeding scale. Following the pilot study, the survey was administered to the population of this study. The structural validity of the scale was good among the current sample, and the structure of each dimension was comparable to the original scales, with eigenvalue >1 for 7 factors (cumulative percentage of variance: 60.388%). The internal reliability was acceptable (Cronbach α: total, 0.765; controlling, 0.740; the use of food as a reward, 0.629; emotional feeding, 0.727; responsiveness to cues, 0.778; active communication and interaction, 0.771; modeling, 0.497; and pressure to eat, 0.441).

In this study, caregivers' frequency of each feeding practice in the previous 1 month was assessed using a 5-point Likert scale (1=never, 2=rarely, 3=sometimes, 4=often, and 5=always). The score for each feeding dimension was obtained by calculating the mean score of the items within the dimension. To calculate the overall score of responsive feeding, the scorings for nonresponsive feeding practices were first reversed, followed by taking the mean value of all responsive and nonresponsive feeding items. A higher overall score indicated a greater tendency to adopt responsive feeding practices.

Data Analysis

Participants' demographic characteristics and the scores of caregivers' responsive/nonresponsive feeding practices were described. Frequencies and percentages have been presented for categorical variables. Continuous variables in this study did not meet normal distribution according to a normality test, and thus, they have been presented using medians and quartiles. Mann-Whitney *U* and Kruskal-Wallis tests were used to examine the univariate association between caregivers' responsive/nonresponsive feeding practices and participants' demographic characteristics. Finally, multiple linear regression was used to determine the independent effects of participants' demographic characteristics on caregivers' responsive/nonresponsive feeding practices. Variables with $P<.10$ in the univariate analysis were entered into the regression model. A variance inflation factor of <5 was used to indicate a low degree of multicollinearity of the independent variables. Statistical analyses were performed using SPSS 22.0 (IBM Corp). A P value of <.05 was considered statistically significant.

Video Observation

Study Design and Participants

A video observation study was conducted from August to October 2020 in Luannan County, Tangshan City, Hebei Province, China. Eligible participants were infants and toddlers, and their primary caregivers. The inclusion criteria were the same as those for the survey, and caregivers were required to agree to participate in this observation study. Referring to previous video observation studies on feeding practices [14,19-21] and considering the time, financial, and human resources of this study, 42 caregiver-child pairs were recruited for this study, including 21 pairs each for children aged 6 - 23 months and those aged 24 - 35 months.

Recruitment and Data Collection

Convenience sampling was used to recruit participants. Researchers were led by village committee staff for household visits. Eligible caregivers were informed of the purpose and procedure of the study. Caregivers who agreed to take part in this study signed a written informed consent form and filled in a brief questionnaire on demographic information. The researchers made appointments with the caregivers for the time

XSL•FO
RenderX

and place to carry out video recording. The caregivers were required to prepare meals and feed their children in a daily routine manner. On the day of the video recording, the researchers (who played the role of a videographer) dressed in a normal style so as not to arouse the curiosity or anxiety of the children. The researchers recorded the children's dining occasions of breakfast, lunch, and dinner, according to the instructions of the operation manual (see Multimedia Appendix 1 for details). For younger infants, 2 - 3 complementary meals were recorded. The total duration of the videos was about 1.5 hours for each caregiver-child pair. After completing each feeding episode, the researchers performed a quality check (eg, whether the picture was clear and whether the sound was recognizable). If the quality was not up to standard, the corresponding meal was recorded again on a later date until the quality of the video was assured. Upon the completion of all recordings, each caregiver received 100 RMB (US $14) as an incentive. All videos were saved to a password-protected removable hard drive and kept confidential by the researchers.

Pilot Study

Three households (one each for children aged <12 months, 12-23 months, and 24 - 35 months) were selected to record children's dining episodes within a day. The pilot study discovered that a meal lasted 5 - 30 minutes, and both caregivers and children could easily get used to the recording. The number of feeding episodes recorded (2 - 3 times per day) was acceptable to both the participants and researchers. Based on the pilot study, the researchers revised and finalized the operation manual for video recording (Multimedia Appendix 1).

Video Coding and Quality Control

Based on the literature, responsive (responsiveness to cues, active communication and interaction, modeling, and creating a good meal environment) and nonresponsive (controlling, the use of food as a reward, emotional feeding, and pressure to eat) feeding practices included 4 dimensions each [3,5,11]. All videos were viewed, and the practices of responsive and nonresponsive feeding were recorded and summarized into a codebook (Multimedia Appendix 2). Notably, the practice of emotional feeding could not be observed in the videos taken, and thus, this was not coded. Next, the number of times each practice appeared was recorded according to the codebook. Taking responsiveness to cues as an example, a caregiver was considered to have this practice as long as any of the corresponding behaviors were shown. A consecutive practice with an interval of <5 seconds was counted as 1, while the same practice with an interval of ≥5 seconds was counted as 2. Coding was performed using the Behavioral Observation Research Interactive Software (BORIS) [22], which automatically summarized the number and duration of each practice in each coded video. Regarding the practice of creating a good meal environment, the researcher scored the overall feeding environment for each feeding episode according to the predefined criteria listed in the codebook. When a criterion was met, a score of 1 was obtained. A higher accumulated score indicated that the caregiver was more likely to create a good meal environment. The scores of creating a good meal environment were recorded in Excel software (Microsoft Corp). All videos were coded by 1 researcher (MA), with 20% of the videos randomly selected for double-coding by another trained coder [23]. The intraclass correlation coefficients (ICCs) between the 2 coders for each feeding practice ranged from 0.587 to 0.885 (P<.05), indicating an acceptable level of reliability [24]. Finally, the coding results were processed by counting the number of times the feeding practices occurred at each dining occasion (breakfast/lunch/dinner). The score for creating a good meal environment was also calculated for each dining occasion. The duration of each feeding practice was not analyzed in this study owing to its low ICC values.

Quality control was performed for coding. First, the coders received intensive training on the content of the codebook, the coding process, and the use of coding software before any coding. Second, 20% of double-coding was performed to ensure the reliability of the coding results. Third, each coder signed a data confidentiality agreement before getting access to any data. Video coding was performed on a password-protected computer that was disconnected from the internet during coding. The coding results were kept confidential by the researchers.

Data Analysis

First, participants' demographic characteristics were described, and the chi-square test was used to analyze the difference in demographics between observation and survey participants. Second, the responsive/nonresponsive feeding practices extracted from coding were described, supplementing the results from the survey. Then, for each dining occasion (breakfast/lunch/dinner), the occurrence and observed number of responsive/nonresponsive feeding episodes were presented. The occurrence (%) was calculated as follows: (the number of videos in which responsive/nonresponsive feeding appeared for each occasion/the total number of videos for each occasion) × 100. Since the observed number did not meet a normal distribution, it was described by median (IQR). Statistical analyses were carried out using SPSS 22.0 software, and a P value of <.05 was used to indicate statistical significance.

Results

General Characteristics of the Participants

Among the 444 participants recruited, 16 did not complete the questionnaire; 2 provided ineligible informed consent; 1 provided a duplicate questionnaire; and 16 had a preterm child, had a child with an abnormal birth weight, or had a child of inappropriate age. Finally, a total of 409 participants were included in the survey. Most caregivers were parents (310/409, 75.8%; including 301 mothers), had a high school education or below (282/409, 68.9%), were unemployed (217/409, 53.1%), and had a normal weight status (207/409, 51.7%). The majority of children were aged 24 - 35 months (217/409, 53.1%), were male (214/409, 52.3%), were not the first child in the family (211/409, 51.6%), had a normal weight status (372/409, 93.0%), lived in an extended family (310/409, 75.8%), and had parents with a monthly household income of >5000 RMB (>US $721; 247/409, 60.4%) (Table 1).

[b]A currency exchange rate of 1 RMB=US $0.14 is applicable.

A total of 42 caregiver-child pairs were included in the video observation, including 21 pairs each of children aged 6 - 23 months and those aged 24 - 35 months. In general, the characteristics of the participants in the video observation and survey were similar (Table 1).

Responsive and Nonresponsive Feeding Practices

The survey measured 7 dimensions of feeding practices. The scores for responsive feeding practices were generally higher than those for nonresponsive feeding practices. The median scores for responsiveness to cues, modeling, and active communication and interaction were 4.00, 3.67, and 3.88, respectively. The median scores for controlling, pressure to eat, the use of food as a reward, and emotional feeding were 3.33, 2.33, 3.00, and 2.67, respectively. The overall responsive feeding score was 3.52 (Table 2).

Table . Scores of responsive and nonresponsive feeding practices in the survey (N=409).

Behavior	Quartile		
	P_{25}[a]	P_{50}[b]	P_{75}[c]
Nonresponsive feeding practices			
Controlling	2.67	3.33	4.00
Pressure to eat	1.67	2.33	3.00
Use of food as a reward	2.00	3.00	3.50
Emotional feeding	2.00	2.67	3.00
Responsive feeding practices			
Responsiveness to cues	3.67	4.00	4.33
Modeling	3.00	3.67	4.00
Active communication and interaction	3.50	3.88	4.25
Overall score of responsive feeding	3.36	3.52	3.76

[a]P_{25}: 25th percentile.

[b]P_{50}: median.

[c]P_{75}: 75th percentile.

Video observation additionally assessed the dimension of “creating a good meal environment” that could not be examined by the survey. Except for caregivers’ emotional feeding, all dimensions could be observed by the videos (Table 3). A total of 105 videos were recorded, including 27 videos for breakfast, 37 for lunch, and 41 for dinner. In general, the occurrences of responsive feeding practices (75.6% - 97.6%) were higher than those of nonresponsive feeding practices (0% - 46.3%) at main meals. There was little variation in the occurrence of each practice during breakfast, lunch, and dinner. In addition, among nonresponsive feeding, controlling and pressure to eat were more likely to occur than the use of food as a reward. The practice of the use of food as a reward appeared at breakfast and dinner but not at lunch (Table 3). Notably, the practice of the use of food as a reward is very likely to occur during snacking, which was not recorded in this study. Therefore, the occurrence of the use of food as a reward reported here is likely to be underestimated. In terms of the observed number of practices at each dining occasion, the observed number of responsive feeding practices (2-11) was higher than that of nonresponsive feeding practices (0). The score for creating a good meal environment was high at 4 points. For each feeding practice, the observed number and scores at breakfast, lunch, and dinner were similar (Table 4).

XSL•FO
RenderX

Table . Occurrence of responsive and nonresponsive feeding practices at main meals in the video observation.

Behavior[a]	Occurrence, n (%)		
	Breakfast (n=27[b])	Lunch (n=37[b])	Dinner (n=41[b])
Nonresponsive feeding practices			
Controlling	11 (41)	17 (46)	19 (46)

[a]Number of videos.

[b]The nonresponsive feeding practice of emotional feeding could not be observed by video in this study.

[c]The responsive feeding practice of creating a good meal environment was evaluated by the score and not the number of observations in the videos.

Observations from the videos provided rich and contextual narratives that illustrated responsive/nonresponsive feeding practices. For instance, the practice of "using food as a reward" frequently involved ultraprocessed foods such as sugary drinks and spicy strips. In 1 episode, a mother promised to provide her child with spicy strips for the purpose of encouraging the child's consumption of the main meal. She said: "OK…spicy strips… If you finish this meal, I will give you spicy strips." Moreover, the practice of "pressure to eat" was observed in the following three dimensions: (1) continue feeding despite the child's refusal (eg, turning the head away and crying), (2) use distractions (eg, toys and mobile phones) to coax the child into eating, and (3) insist on eating even after satiety cues (eg, verbally expressing fullness and pushing the bowl away). Video descriptions of "responsiveness to cues" have been presented in our previous publication [6].

Factors Influencing Responsive and Nonresponsive Feeding Practices

The results from univariate analyses that explored factors influencing responsive/nonresponsive feeding practices are shown in Multimedia Appendix 3. After controlling for potential confounders, the results from multivariate analyses are shown in Table 5. For the overall responsive feeding score, caregivers who were nonparents (β=0.13, 95% CI 0.05-0.21) and had a monthly household income of >5000 RMB (>US $721; β=0.07, 95% CI 0.01-0.14) had a higher overall score, while the score was lower among unemployed caregivers (β=−0.07, 95% CI −0.13 to −0.01). For nonresponsive feeding practices, caregivers whose children were not the first child (β=−0.20, 95% CI −0.39 to −0.02) and whose children were aged 24 - 35 months (β=−0.20, 95% CI −0.38 to −0.02) had a lower score. The score for pressure to eat was higher among unemployed caregivers

XSL•FO
RenderX

(β=0.27, 95% CI 0.11-0.42). The score for the use of food as a reward was lower for caregivers who were nonparents (β=−0.45, 95% CI −0.69 to −0.22). The score for emotional feeding was higher among caregivers whose children were not the first child (β=0.18, 95% CI 0.03-0.34). In terms of responsive feeding practices, the score for responsiveness to cues was higher among caregivers who were nonparents (β=0.43, 95% CI 0.25-0.60), while the score was lower among unemployed caregivers (β=−0.19, 95% CI −0.33 to −0.05). The score for modeling was higher among caregivers whose weight status was underweight (β=0.44, 95% CI 0.07-0.80), and the score was lower among caregivers whose children were aged 24 - 35 months (β=0.22, 95% CI 0.07-0.37). Caregivers whose children were not the first child (β=−0.17, 95% CI −0.29 to −0.54) had a lower score for active communication and interaction.

Discussion

Summary of the Study Findings

This study used a combination of survey and video observation methods to obtain a comprehensive understanding of the current status of caregivers' responsive and nonresponsive feeding practices among children aged 6 - 35 months and performed multivariate analyses of the survey data to explore factors influencing responsive and nonresponsive feeding practices. Both survey and video observation methods found that the frequencies of responsive feeding practices were higher than those of nonresponsive feeding practices. Video observation revealed that there was little variation in the occurrence/score of each feeding practice in main meals (ie, breakfast, lunch, and dinner). The survey demonstrated that caregivers' relationships with their children, employment status, and weight status; children's age and order; and the monthly household income were factors influencing responsive/nonresponsive feeding practices.

Caregivers' Responsive and Nonresponsive Feeding Practices

Both survey and video observation methods in this study found that caregivers adopted responsive feeding practices more frequently than nonresponsive feeding practices. In our survey, the scores for nonresponsive feeding practices were at a moderate to low level, similar to findings reported in other Chinese studies [16,25]. For example, a study in Hong Kong revealed that the scores for the use of food as a reward and emotional feeding were 2.68 (SD 0.66) and 2.31 (SD 0.70) points, respectively [26]. However, the score for pressure to eat among caregivers of children aged 3 - 18 months in Spain was 3.46 (SD 0.82) points [27], which is higher than that in our study. The scores for responsive feeding practices in our study were moderately high and were consistent with the findings of other national and international studies. For instance, a study in the United States revealed that the score for responsiveness to cues among children aged 3 - 18 months was 4.49 (SD 0.04) points [28]. The median scores for behaviors related to active communication and interaction among caregivers whose children were aged 18 months in Shanghai were between 4 and 5 points, indicating a relatively high level [18].

The video observation confirmed the results of the survey. In daily meals, caregivers adopted responsive feeding practices more frequently than nonresponsive feeding practices. Caregivers likely prepared a variety of nutritious foods for their children. Responsive feeding practices, such as modeling, are effective strategies for promoting children's intake of these healthy foods [6]. Furthermore, video observation found that the number of responsive feeding observations was similar among breakfast, lunch, and dinner. Similarly, a video observation study among children aged 12 - 36 months in the United States indicated that caregivers' feeding practices during each main meal had a certain degree of stability. Observation of a single main meal might be an alternative approach to examine responsive feeding in future studies, if resources are limited.

Factors Influencing Caregivers' Responsive and Nonresponsive Feeding Practices

Previous studies on feeding practices were mainly conducted among mothers. Our study adds to the literature by examining responsive and nonresponsive feeding practices among both parents and nonparents. In this study, the scores of overall responsive feeding and the practice of responsiveness to cues among nonparents (99% grandparents) were higher than those among parents. However, the score of the use of food as a reward among nonparents was lower than that among parents. This might be because grandparents were patient and responsible when feeding their grandchildren and had sufficient time to adopt responsive feeding strategies [29,30]. From our video observation, grandparents waited for a while after each feed and did not provide the next feed until the child swallowed the food (data not shown). Moreover, grandparents had previous experience in feeding children. Finally, with the broad use of the internet and smartphones, grandparents were knowledgeable in using appropriate feeding strategies. Our results imply that education on optimal feeding practices should be given to parents. For instance, local maternal and child health centers might deliver responsive feeding guidance (eg, recognizing children's satiety cues and optimizing mealtime interactions) to parents during children's routine health check-ups and vaccination visits. On the contrary, some studies failed to report differences in pressure to eat and the use of food as a reward between grandparents and parents, and some studies found that grandparents were more inclined to adopt the pressure to eat practice than parents [29,31]. Children in these studies were older than our study participants [31], which might explain the variation in results between our study and previous studies.

In this study, compared with employed caregivers, unemployed caregivers scored lower in overall responsive feeding and responsiveness to cues but scored higher in pressure to eat. Moreover, the score of overall responsive feeding was lower among caregivers whose monthly household income was ≤5000 RMB (≤US $721). Caregivers with a lower socioeconomic status likely paid less attention to responsive feeding practices. Likewise, a qualitative study in Thailand among factory worker parents of preschool children demonstrated that family income was one of the most influential factors on children's food choice, as parents prioritized their budget on food over nutritional quality due to economic constraints [32]. Therefore, interventions to enhance responsive feeding in China should attempt to target low-income groups. For example, community health centers might consider offering feeding workshops aligned with intergenerational care norms free of charge for low-income groups. Free personalized consultation could also be provided by community health care workers.

In this study, caregivers of children aged 24 - 35 months had a lower score for controlling and a higher score for modeling, in comparison with caregivers of children aged 6 - 23 months. It is likely that older children could express their dietary signals well, making it easier for caregivers to respond more appropriately. With an increase in their independence, children are more likely to eat on their own [33]. Caregivers' use of the modeling strategy could help the development of children's healthy eating habits. Therefore, specific education on feeding

XSL•FO
RenderX

practices should be delivered to caregivers by considering the age of their children. Caregivers of younger children (less than 24 months of age) urgently need responsive feeding education.

Caregivers whose children were not the first child in the family were more likely to use emotional feeding but less likely to use active communication and interaction, and controlling strategies, in comparison with caregivers whose children were the first child. Based on the theory of family systems, the dilution of resources (time, energy, etc) for raising multiple children may affect caregivers' feeding practices [34]. With an increase in the number of children in the family, caregivers' time and energy allocated to each child decrease. Therefore, the frequency of caregiver-child interaction and verbal communication during feeding decreases [34]. Caregivers' practice of controlling children's eating also decreases. Caregivers are more likely to become impatient and use emotional feeding. However, a cross-sectional study in Thailand reported that the first child was more likely to receive inappropriate complementary feeding [35]. The Thai study focused on children's dietary intake and diversity, while our study focused on the behaviors of the caregiver-child interaction. Differences in research focus might account for the variations in findings between the studies.

Compared with caregivers having a normal weight status, underweight caregivers in this study adopted more modeling behaviors. The reason may be that underweight caregivers are more concerned about insufficient dietary intake or being underweight in childhood, and thus, they play the role of an eating model for their children and ensure that their children have a good nutritional status.

Notably, there was no difference in responsive/nonresponsive feeding practices when considering the child's gender. It appears that Chinese traditional patriarchal attitudes did not influence caregivers' feeding practices among our study participants. Additionally, caregivers' education, children's weight status, and the family structure were not associated with caregivers' responsive/nonresponsive feeding practices in this study.

Strengths and Limitations

This study adopted a combined approach involving survey and video observation methods to investigate responsive/nonresponsive feeding practices among caregivers of children aged 6 - 35 months. This approach provided an objective and comprehensive assessment of responsive/nonresponsive feeding practices. Findings from the survey and observation assessments were confirmatory and complementary to each other. The questionnaire had good reliability and validity and could comprehensively measure all dimensions of responsive and nonresponsive feeding practices. Video observation could objectively capture the actual feeding environment and caregiver-child interaction and assess the practice of "creating a good meal environment," which could not be measured by questionnaires. Moreover, this study used multivariate analysis to explore the factors influencing responsive and nonresponsive feeding practices. The findings of this study would be useful in the development of interventions and strategies to promote responsive feeding and in the identification of targeted populations for interventions.

The limitations of this study should be acknowledged. First, this study was conducted in some areas of Hebei Province. The results from this study might not be representative of caregivers living in other areas. Moreover, the caregivers in our survey sample had a higher education level but a lower employment rate than the general population [36]. National data indicate that the population in Hebei Province is at the top level and its economic output (reflected by gross domestic product) is at the middle level in China [36]. The health literacy of residents in Hebei Province [37] was similar to that at the national level (27.78%), according to 2022 surveillance data [38], implying that our findings might represent the Chinese population to some extent. Second, the use of food as a reward is more likely to occur in snacking occasions than during main meals. However, our video observation only recorded feeding episodes during main meals. Thus, the occurrence of the use of food as a reward reported in our video observation might be lower than the actual status. Third, owing to the COVID-19 epidemic, video observation could not be carried out at the planned location (Shijiazhuang city, where the survey was conducted). After careful discussion by the research team, Tangshan city was selected as an alternative location. The 2 cities are located in the same province, with a distance of 420 kilometers, ensuring the homogeneity of the samples to some extent. Fourth, the Hawthorne effect may have existed in the video recording process owing to the presence of the camera or videographer. Nevertheless, a number of efforts were taken to minimize the Hawthorne effect. For instance, we conducted the recording in a familiar environment (ie, home); we explicitly instructed caregivers to behave as usual prior to each recording; and the videographer dressed normally, remained silent, stayed hidden in a corner, and avoided participating in any feeding practices during the recording.

Conclusion

With a combined approach involving survey and video observation methods, this study revealed that the frequency of responsive feeding practices was higher than that of nonresponsive feeding practices among Chinese caregivers whose children were aged 6 - 35 months. The combined approach might serve as a methodological reference for research on feeding practices. Moreover, the survey demonstrated that parental, unemployed, and low-income caregivers were less likely to use responsive feeding strategies. Health care providers should consider this finding and target such groups for feeding education and intervention.

Abstract

Background: Parents of young children with type 1 diabetes (T1D) frequently report fear of hypoglycemia (FH), which can impact their diabetes management. REDCHiP (Reducing Emotional Distress for Childhood Hypoglycemia in Parents) is a telehealth-delivered cognitive behavioral intervention shown to reduce FH, but less is known about which parents benefit most.

Objective: This secondary analysis examined whether pretreatment parent anxiety moderated REDCHiP's effects and explored responder patterns by intervention arm and pretreatment anxiety.

Methods: This was a secondary analysis of a large, randomized clinical trial comparing REDCHiP to an attention control condition (ATTN). We assessed outcomes before treatment (time 1) and 3 months after treatment (time 3). Our primary outcome was parental FH at time 3, adjusted for time 1 FH. The original trial used validated measures of parent FH and general anxiety. We evaluated parent anxiety at time 1 as both a categorical variable (clinically elevated or not) and a continuous variable (centered). We defined responders as parents achieving a reduction of ≥0.5 SDs in FH from time 1 to time 3. An analysis of covariance tested the treatment arm by anxiety interaction, with sensitivity analyses modeling anxiety continuously.

Results: There was no significant treatment arm by anxiety interaction when modeling parent anxiety as either a categorical or continuous variable (P>.05). However, exploratory analyses found that the adjusted mean time 3 FH was numerically lower among REDCHiP parents than ATTN parents with clinically elevated anxiety. Among parents with elevated anxiety, 78.6% (22/28) of REDCHiP parents met our responder criterion compared with 47.4% (9/19) of ATTN parents. Among parents with elevated anxiety, the adjusted odds of meeting the responder criterion were higher for REDCHiP than ATTN parents (odds ratio 6.35, 95% CI 1.47 - 29.00).

Conclusions: While time 1 parent anxiety did not significantly moderate treatment response, exploratory analyses suggested a potentially meaningful pattern among parents with clinically elevated anxiety. As telehealth-delivered behavioral interventions expand in pediatric type 1 diabetes care, secondary analyses of participant characteristics may help guide targeted implementation and enhance treatment benefit.

Trial Registration: ClinicalTrials.gov NCT03914547; https://clinicaltrials.gov/study/NCT03914547

KEYWORDS

pediatrics; type 1 diabetes; hypoglycemia fear; parenting; anxiety

Introduction

Parents of young children with type 1 diabetes (T1D) commonly report fear of hypoglycemia (FH) [1,2], which may adversely influence their treatment decisions and consequently young children's glycemic control [2]. To address this concern, we designed REDCHiP (Reducing Emotional Distress for Childhood Hypoglycemia in Parents), a telehealth-based intervention to reduce parent FH [3]. Telehealth-delivered treatments may be more scalable for families managing T1D because they can reduce barriers associated with traditional in-person treatments, including transportation demands, time and scheduling constraints, and childcare responsibilities [4-7]. However, as the availability of telehealth interventions continues to expand [4,7], it is essential to identify which families are

XSL•FO
RenderX

most likely to benefit so that we can implement programs efficiently and target the families with the greatest need.

Parent anxiety is an established correlate of FH [8-10], and higher anxiety may amplify the constant vigilance, worry, and avoidance behavior that characterizes FH. Because REDCHiP teaches parents cognitive and behavioral strategies for managing FH worry and reducing their reliance on potentially harmful hypoglycemia avoidance behaviors [3], it is possible that parents' pretreatment anxiety symptoms could influence their engagement with or responsiveness to treatment.

We recently completed a large 2-arm randomized clinical trial comparing REDCHiP to a study-specific attention control condition (ATTN) [11]. In the main trial, parents in both treatment arms experienced a significant reduction in FH [12]. Here, we present secondary analyses exploring pretreatment parent characteristics that may have been associated with parent treatment response. Specifically, we examined whether parents' pretreatment anxiety moderated reductions in parent FH. We also explored response patterns among participants by treatment group and their pretreatment anxiety level.

Methods

Ethical Considerations

We conducted the primary multisite clinical trial under a single institutional review board (IRB) agreement, with Children's Mercy Hospital-Kansas City as the IRB of record. Before enrolling parents, we obtained IRB approval on all study procedures, including the use of electronic documentation of parent informed consent and permission. The primary trial was registered at ClinicalTrials.gov (NCT03914547).

Study Design

We previously described the primary trial's inclusion and exclusion criteria, study procedures, and trial outcomes [11,12]. We randomized families following enrollment. We delivered the REDCHiP and ATTN treatments entirely via video telehealth following guidelines for best practices in digital behavioral health [13]. Both treatment arms had 10 sessions delivered nearly weekly over 12 weeks. We assessed parent outcomes at before treatment (time 1), immediately after treatment (time 2) and 3 months after treatment (time 3). To be consistent with the primary analyses from the REDCHiP trial, these secondary analyses also focused on outcomes at time 3 to examine maintenance of treatment effects.

Measures

Overview

All participating parents completed the same questionnaires online [11,12]. At time 1, we used a trial-specific questionnaire to capture family demographics, including parent and child age, sex, and race and ethnicity. We also asked parents to describe their relationship to the child, marital status, and education level, as well as provide information on their child's T1D, including date of diagnosis, treatment regimen, and history of severe hypoglycemia.

Hypoglycemia Fear

Parents completed the validated Hypoglycemia Fear Survey–Parents of Young Children (HFS-PYC) [2]. This questionnaire measures parents' FH based on the frequency of hypoglycemia-related worries and avoidance behaviors. Items used a 5-point Likert scale (1=never to 5=very often), with higher scores indicating greater FH. To simplify score interpretation, the primary trial transformed HFS-PYC scores to fit a 0 to 100 scale [12]; we applied the same rescoring method to the current analyses. To calculate a responder variable, we defined treatment response as parents who achieved a reduction of ≥0.5 SD from time 1 to time 3 using the time 1 HFS-PYC SD from the full sample [14]. We used this distribution-based approach because a minimal clinically important difference has not yet been established for the HFS-PYC [15].

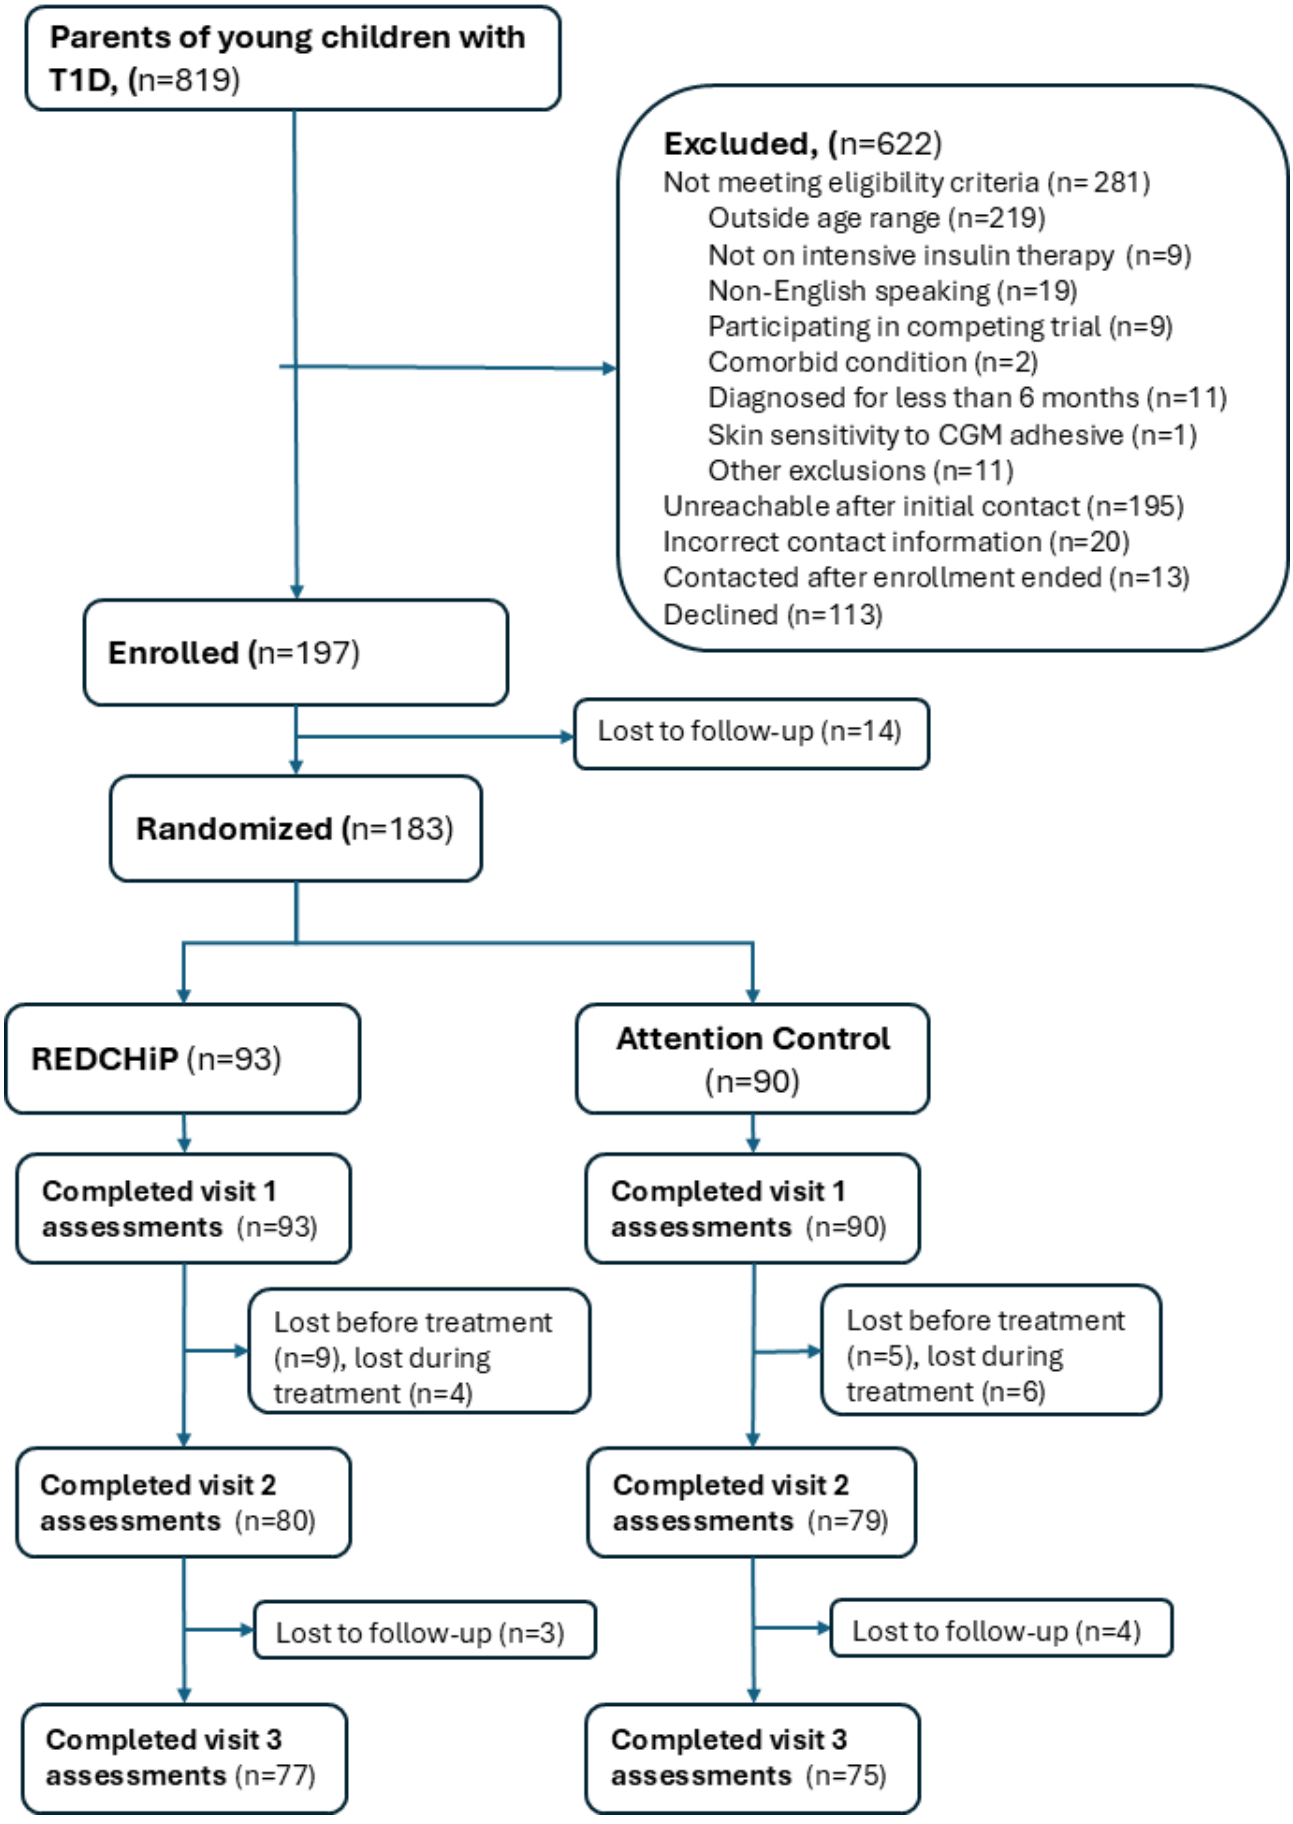
General Anxiety

Parents completed the PROMIS-A (Patient-Reported Outcomes Measurement Information System Anxiety Short Form). This is a validated 7-item questionnaire assessing physical and cognitive symptoms of general anxiety over the past 7 days. Items used a 5-point Likert scale reflecting the frequency or intensity of symptoms. We selected parent anxiety as a candidate moderator based on theory and empirical findings linking elevated anxiety to greater FH [8-10]. We examined parent anxiety at time 1 as both a continuous variable, to capture the full range of symptom severity, and as a categorical variable based on normative guidelines to identify parents with or without clinically elevated anxiety (PROMIS-A T-scores ≥60) [16].

Statistical Analysis

Our primary model was an analysis of covariance examining time 3 parent FH. The model included treatment arm, time 1 anxiety (elevated versus not elevated), and the treatment arm by anxiety interaction as fixed factors and time 1 parent FH as a covariate. We also conducted a sensitivity analysis that modeled parent PROMIS-A T-scores as a continuous, centered variable, and retested the treatment arm by anxiety interaction. Finally, we explored responder rates by time 1 anxiety (elevated versus not elevated) by treatment arm. Among parents with elevated anxiety, we used logistic regression to explore whether responder rates differed by treatment arm after adjusting for time 1 parent FH. We conducted all analyses using SPSS (version 27; IBM Corp).

Results



Of the 183 families randomized, 152 (83%) completed time 3, including 77 and 75 families randomized to REDCHiP and ATTN, respectively (Figure 1). Thirty-one families were lost to follow-up during the primary trial. There were no significant differences in time 1 demographics, child clinical characteristics, or parent-reported FH and general anxiety among those who completed the trial versus those who withdrew (Multimedia Appendix 1).

Table 1 summarizes family demographics at time 1. There were no significant time 1 differences in family demographics or child T1D characteristics based on treatment arm. Likewise, there were no significant differences in time 1 parent FH or time 1 parent general anxiety. There was a significant group difference in time 3 parent FH. Specifically, parents randomized to REDCHiP reported lower time 3 FH than parents randomized to ATTN. At time 1, parents with elevated anxiety reported significantly higher FH (mean 64.1, SD 11.6) than parents without elevated anxiety (mean 53.3, SD 13.6; $P<.001$).

Table . Sample characteristics and outcome measures by treatment arm[a].

	Overall (n=183)	REDCHiP[b] (n=93)	ATTN[c] (n=90)	*P* value
Demographics				
Child age at time 1 (y), mean (SD)	4.4 (1.2)	4.5 (1.2)	4.3 (1.2)	.12
Child sex, male, n (%)	100 (54.6)	51 (54.8)	49 (54.4)	.54
Parent age at time 1 (y), mean (SD)[d]	36.3 (5.9)	36.7 (5.3)	35.9 (6.6)	.26
Clinical characteristics				
Time since diagnosis at time 1 (y), mean (SD)[e]	1.7 (1.1)	1.5 (1.0)	1.8 (1.3)	.11
Continuous glucose monitoring use, n (%)	151 (82.5)	78 (83.9)	73 (81.1)	.36
Automated insulin delivery use, n (%)	93 (50.8)	45 (48.4)	48 (53.3)	.25
HFS-PYC[f] total score at time 1, mean (SD)	56.4 (14.0)	55.4 (13.6)	57.4 (14.4)	.32
HFS-PYC total score at time 3, mean (SD)[g]	49.2 (11.0)	46.9 (9.5)	51.3 (12.1)	.009
Parent PROMIS-A[h] total score at time 1, mean (SD)	54.6 (9.8)	54.8 (10.0)	54.4 (9.5)	.77
Parents with clinically elevated anxiety at time 1, n (%)	54 (29.5)	31 (33.3)	23 (25.6)	.17

[a]Full description of time 1 sample characteristics is reported elsewhere [12]; the variables reported here are relevant to the current secondary analyses.

[b]REDCHiP: Reducing Emotional Distress for Childhood Hypoglycemia in Parents.

[c]ATTN: attention control condition.

[d]Data were available for 177 participants overall (REDCHiP: n=90; ATTN: n=87).

[e]Data were available for 182 participants overall (REDCHiP: n=93; ATTN: n=89).

[f]HFS-PYC: Hypoglycemia Fear Survey–Parents of Young Children.

[g]Data were available for 152 participants overall (REDCHiP: n=77; ATTN: n=75).

[h]PROMIS-A: Patient-Reported Outcomes Measurement Information System Anxiety Short Form.

In our primary model, the treatment arm by anxiety interaction was not statistically significant ($F_{1,146}=2.40$; $P=.12$; partial $\eta^2=0.016$; Table 2). The main effect of REDCHiP was significant ($F_{1,146}=6.58$; $P=.01$; partial $\eta^2=0.043$), suggesting lower adjusted time 3 HFS-PYC scores among parents in the REDCHiP arm. Additionally, adjusted means showed larger absolute differences between REDCHiP and ATTN parents with clinically elevated anxiety (45.8, SD 1.75 vs 52.6, SD 2.12 for REDCHiP and ATTN, respectively) versus parents without elevated anxiety (48.6, SD 1.33 vs 50.3, SD 1.19 for REDCHiP and ATTN, respectively), though these subgroup patterns should be interpreted cautiously in light of the nonsignificant moderation effects.

Table . Analysis of covariance models examining time 1 anxiety and time 3 parent fear of hypoglycemia[a].

Predictor	*F* test (*df*)	*P* value	Partial η^2
Anxiety measured categorically			
Treatment arm	6.58 (1, 146)	.01	0.043
Elevated anxiety	0.013 (1, 146)	.91	0.001
Treatment arm×elevated anxiety	2.40 (1, 146)	.12	0.016
Time 1 HFS-PYC[b]	58.29 (1, 146)	<.001	0.285
Anxiety measured continuously			
Treatment arm	4.72 (1, 146)	.03	0.031
PROMIS-A[c] (centered)	0.004 (1, 146)	.95	0.001
Treatment arm×PROMIS-A	1.48 (1, 146)	.22	0.010
Time 1 HFS-PYC	51.70 (1, 146)	<.001	0.261

[a]Both models included time 1 HFS-PYC as a covariate and 151 participants with complete data.

[b]HFS-PYC: Hypoglycemia Fear Survey–Parents of Young Children.

[c]PROMIS-A: Patient-Reported Outcomes Measurement Information System Anxiety Short Form.

In a follow-up model with time 1 parent anxiety measured as a continuous variable, the treatment arm by anxiety interaction was also not significant ($F_{1,146}$=1.48; *P*=.22; partial η^2=0.010). However, the main effect of REDCHiP remained significant ($F_{1,146}$=4.72; *P*=.03; partial η^2=0.031; Table 2).

Within the REDCHiP arm, 78.6% (22/28) of parents with clinically elevated time 1 anxiety met our responder criterion for reduced time 3 parent FH. In comparison, 47.4% (9/19) of parents with elevated time 1 anxiety in the ATTN arm met our responder criterion (Table 3). In an exploratory logistic regression among parents with clinically elevated time 1 anxiety and adjusting for time 1 FH, REDCHiP parents had greater odds of meeting responder criteria than ATTN parents (odds ratio [OR] 6.35, 95% CI 1.47-29.00; *P*=.01). For context, responders in both treatment groups reported higher time 1 FH than nonresponders (*P*<.001), suggesting that greater time 1 FH may have provided more opportunity for improvement. Among REDCHiP parents, responders also reported higher time 1 anxiety than nonresponders (*P*=.004).

Table . Fear of hypoglycemia responder rates at time 3 by treatment arm and time 1 parent anxiety.

Time 1 anxiety	REDCHiP[a] parents		ATTN[b] parents	
	Responders, n (%)	Nonresponders, n (%)[c]	Responders, n (%)	Nonresponders, n (%)
Elevated	22 (78.6)	6 (21.4)	9 (47.4)	10 (52.6)
Not elevated	17 (34.7)	32 (65.3)	28 (50)	28 (50)

[a]REDCHiP: Reducing Emotional Distress for Childhood Hypoglycemia in Parents.

[b]ATTN: attention control condition.

[c] Percentages are calculated within each treatment arm and anxiety subgroup. Subgroup sample sizes were n=28 (REDCHiP) and n=19 (ATTN) for elevated anxiety, and n=49 (REDCHiP) and n=56 (ATTN) for nonelevated anxiety.

Discussion

In this secondary analysis of REDCHiP, we found that parents' time 1 anxiety did not significantly moderate treatment response when modeled as either a categorical (*P*=.12) or continuous (*P*=.22) variable. However, exploratory results revealed a potentially meaningful pattern among parents with clinically elevated anxiety. Specifically, we found that adjusted time 3 FH scores were numerically lower in REDCHiP than in ATTN, and 78.6% (22/28) of REDCHiP parents with elevated anxiety met the responder criterion compared with 47.4% (9/19) of ATTN parents with elevated anxiety. Moreover, results of an exploratory logistic regression restricted to parents with elevated anxiety and adjusting for time 1 FH suggested that REDCHiP parents had 6-fold greater odds of meeting the responder criterion than ATTN parents.

We designed REDCHiP to address parents' challenges with worry, hypervigilance, and avoidance related to childhood hypoglycemia [3,11]. While the current analyses did not support a significant moderating role for parent anxiety, the adjusted mean and responder findings suggest that it still may be worth considering parents' time 1 anxiety symptoms when examining response to cognitive behavioral interventions for FH. One possible reason is that, although REDCHiP specifically targets FH, the cognitive and behavioral skills it teaches may generalize to broader, nondiabetes-specific worries and anxiety. As a result, it is possible that parents with elevated anxiety may derive benefits from REDCHiP that extend beyond FH. However, this

XSL•FO
RenderX

interpretation remains speculative. We will need larger trials with adequate power to evaluate moderator effects to determine whether these observations reflect meaningful differences in treatment response.

The results also complement the primary trial outcomes, which showed that parents across both treatment arms experienced overall reductions in FH [12]. Whereas the primary trial focused on whether REDCHiP reduced FH, these secondary analyses examined variability in treatment response and provided additional context for interpreting response patterns among trial participants.

Strengths of this study include the use of validated questionnaires and sensitivity analyses examining anxiety as both a categorical and continuous variable. As a limitation, we acknowledge that any reported subgroup differences among parents with clinically elevated time 1 anxiety should be regarded as exploratory because neither treatment arm by anxiety interaction was statistically significant. We acknowledge a risk of bias because we used complete cases rather than an intention-to-treat approach. However, post hoc comparisons of trial completers versus noncompleters on time 1 demographic and clinical characteristics yielded no significant differences. Our responder analyses were also post hoc, exploratory, and for the logistic regression, were restricted to a small subgroup of our sample; they should be interpreted cautiously and considered hypothesis generating. Relatedly, we acknowledge that for both treatment arms, responders reported higher time 1 FH than nonresponders, suggesting that time 1 FH severity and greater opportunity for improvement may have contributed to responder classification and should be considered when interpreting the clinical significance of these findings. Although our sample reflects the demographic characteristics of families typically seen in pediatric T1D care centers in the United States [17], the findings may not generalize to families from other clinical settings. Replication in future samples powered specifically for moderation and recruiting families from more diverse clinical samples will be important.

In conclusion, time 1 parent anxiety did not significantly moderate treatment response. However, in exploratory analyses, we found that REDCHiP parents with clinically elevated anxiety demonstrated lower adjusted FH scores and higher responder rates than comparable ATTN parents. While these exploratory results should be interpreted cautiously, they point to a clinically interesting pattern that warrants investigation in future studies. Additionally, as digital and telehealth-delivered behavioral health interventions continue to expand within pediatric diabetes care, this study highlights a need for further research examining the patient or family member characteristics associated with treatment response and how to use this information to match families to interventions that may improve reach, efficiency, and impact.

Acknowledgments

The authors thank the families who participated in the trial. The authors also acknowledge the contributions of Ms Amy Milkes, Ms Emily Shaffer, Ms Bailey Tanner, Mr Andrew McConville, Dr Alexandra Monzon, Dr Paige Trojanowski, Dr Alicia Pardon, Dr Cheyenne Reynolds, and Dr Sara Wetter-Wren, whose efforts made the trial possible.

Generative AI Use

The authors used Microsoft 365 Copilot to assist with proofreading and editing the manuscript and the response to reviewer comments. The authors reviewed all suggested revisions and take full responsibility for the final content.

Funding

The trial was supported by a grant (principal investigator: SRP) from the National Institute of Diabetes and Digestive and Kidney Diseases (R01 DK118514).

Data Availability

Data supporting the findings of the larger trial are not publicly available due to participant privacy and institutional restrictions. Deidentified data may be made available upon reasonable request to the corresponding author, contingent on appropriate data use agreements and ethical approvals.

Authors' Contributions

SRP wrote the first draft and reviewed and edited the manuscript. AM, NK, JR, and KD contributed to the discussion and reviewed and edited the manuscript.

Conflicts of Interest

SRP reports receiving grants from the National Institutes of Health, receiving an honorarium from the American Diabetes Association, and serving on a clinical advisory board for Glooko, Inc. AM, NK, JR, and KD report no conflicts of interest.

Abstract

Background: The Strong Families (SF) Program, developed by the United Nations Office on Drugs and Crime, is an evidence-informed family skills intervention designed to support caregivers and children in low-resourced, high-stress circumstances. Following a pilot phase, we revised the program materials according to the expert trainers' suggestions to best reflect the needs of the target population.

Objective: This study aimed to evaluate the feasibility, effectiveness, and cultural adaptability of the second phase of the SF Program expansion in northern Thailand.

Methods: This prospective mixed methods pretest-posttest feasibility cohort study involved 68 families (caregivers and children as 1:1) from Chiang Mai, Lamphun, and Chiang Rai—3 provinces in northern Thailand. The applied intervention consisted of a 3-week program with both separate and joint sessions for caregivers and children. Quantitative data were collected using the Parent and Family Adjustment Scales, Strengths and Difficulties Questionnaire, and Child and Youth Resilience Measure–Revised–Person Most Knowledgeable About the Child. Data were analyzed using linear mixed-effects regression. Qualitative data were gathered through semistructured interviews with 19 families and analyzed using content analysis to identify key themes.

Results: Quantitative analysis using linear mixed-effects regression revealed significant improvements in coercive parenting (β=−0.10; *P*=.003), child conduct problems (β=−0.04; *P*=.002), and peer relationship problems (β=−0.04; *P*=.048) for parents and in emotional (β=–0.05; *P*=.01) and conduct (β=−0.04; *P*=.02) behavior for children. However, scores for positive encouragement (β=0.05; *P*=.009) and parent-child relationship (β=0.28; *P*<.001) significantly declined, a discrepancy that may be due to response shift bias, in which participants adopt stricter self-evaluation standards after the intervention. Qualitative findings showed 5 themes that highlighted improved family atmosphere, better emotional regulation, and successful translation of knowledge into practice to better develop protective factors for young people. Participants viewed the program as feasible and culturally appropriate but recommended extending the duration and increasing paternal involvement for more significant, sustainable outcomes.

Conclusions: The SF Program is a culturally adaptable and effective intervention for improving family dynamics in low-resource settings.

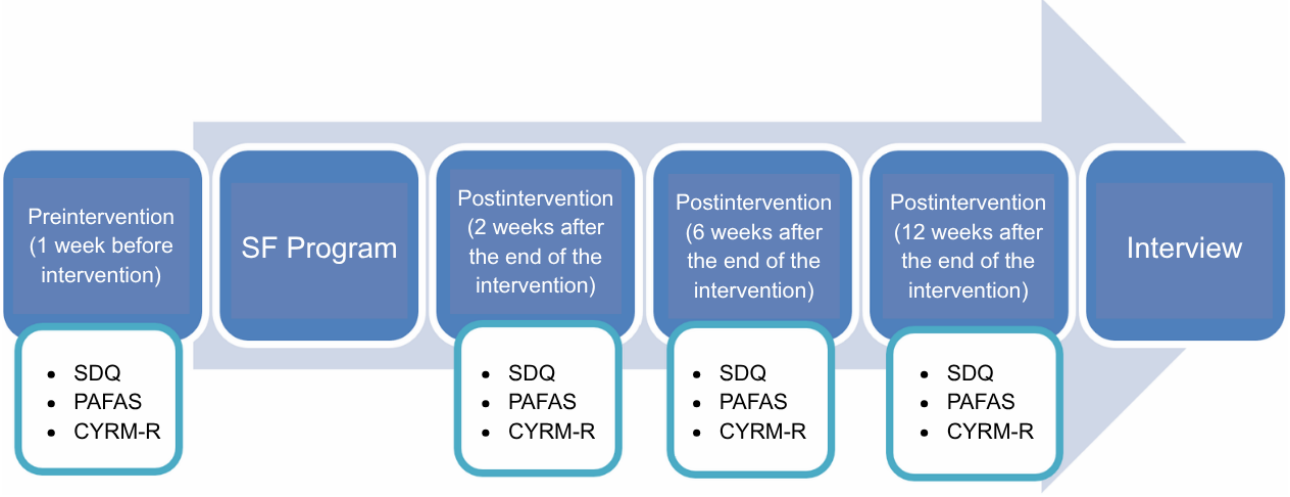
Introduction

Families worldwide face a range of adversities that undermine their capacity to provide safe and nurturing environments for children. These challenges include unemployment, schooling barriers, and limited access to goods and services in rural and underserved areas [1], as well as migration, displacement, residence in refugee camps, and exposure to conflict or postconflict situations [2]. Such circumstances place significant strain on caregivers and compromise their ability to engage in responsive, supportive parenting. Children's earliest and most formative interactions occur within the family, well before they reach school age, and those whose caregivers lack nurturing abilities, parenting skills, or the capacity to manage stressors such as poor health or financial hardship are at heightened risk of maladjustment across cognitive, emotional, and behavioral domains [3,4]. Strengthening family skills and competencies is therefore essential not only to support caregivers but also to foster the safe, stable, and nurturing relationships that promote children's healthy development and the well-being of both caregivers and children [5].

The United Nations Office on Drugs and Crime (UNODC) has implemented evidence-based family skills prevention programs in low- and middle-income countries worldwide since 2010 [6]. In 2017, the Strong Families (SF) Program was developed [7]. The program is designed for families in underserved settings, offering an evidence-informed prevention response that builds family skills to benefit the health and safe development of children. This program can be easily adapted to serve families in different contexts facing adverse circumstances. SF helps caregivers and children manage daily stressors and difficulties, aiming to strengthen family structures and functions to prevent drug use, violence, and other negative social consequences in their children. It is a universal program within this selective subgroup of families and is best suited for families with children aged between 8 and 15 years [7].



More than 30 countries have implemented the SF Program and found it effective in improving family relationships and parenting skills. SF was initially created and tested in Afghanistan and has since been implemented in Central America, Central and West Asia, and East and West Africa. An early 2024 pilot study of SF in Thailand was evaluated and refined based on the results of a previous project [8]. SF was found to be feasible to implement in Thailand during this first phase. The program strengthened family relationships and improved mutual understanding among family members. However, several challenges were identified, including language barriers, cultural mismatches in the materials, and difficulty handling challenging situations arising during program facilitation. In phase 2 (late 2024), several materials were adapted for the target population. Revisions included using simpler Thai words, Asian faces, and pictures that were easy to understand in the Thai cultural context. Training sessions for trainers, including skills to offer brief interventions, advice, and strategies for handling difficult situations during program implementation, were incorporated into program preparation. Therefore, the objective of this study was to evaluate the program's feasibility, effectiveness, and adaptability for further expansion in the country.

Methods

Study Design

This study used a mixed methods, pretest-posttest feasibility design with a prospective cohort of participants enrolled in the SF Program. Phase 2 ran a follow-up data collection at 4 time points (before the intervention and at 2, 6, and 12 weeks after the end of the intervention). The pretest was completed prior to the first week, and the posttest was completed within 12 weeks of the final programming date for estimating the long-term outcomes. Additional qualitative interviews were conducted between August 2025 and September 2025, approximately 12 weeks following the last session. Figure 1 illustrates the study timeline.

Figure 1. Study timeline. CYRM-R: Child and Youth Resilience Measure–Revised; PAFAS: Parent and Family Adjustment Scales; SDQ: Strengths and Difficulties Questionnaire; SF: Strong Families.

The SF Program

This program was conducted between June 2025 and July 2025 in the Chiang Mai, Chiang Rai, and Lamphun provinces in northern Thailand, encompassing 8 study locations in total. Training for the Trainers of the SF Program was a 3-day workshop for trainers who would conduct SF in their local geographic areas. The workshop was led by master trainers certified by UNODC. The SF Program consisted of 3 sessions held on 3 consecutive weekends engaging caregivers and children. The first session was exclusively for caregivers, whereas children participated in parallel and joint activities in the second and third sessions, respectively. The topics for caregivers were (1) understanding strengths and stressors, (2) using love and limits, and (3) teaching children what is right. The topics for children were (1) learning about stress and (2) following rules and appreciating parents. The topics for joint sessions were (1) learning about each other and (2) supporting values and dreams. To ensure implementation fidelity, UNODC-certified master trainers attended and provided feedback for the Thai trainers at community sites during the first session of the SF Program.

Participants

The target population for this study consisted of the families (specifically, the caregivers and their children) who participated in the SF Program phase 2. We used a convenience sampling strategy recruiting 68 volunteer families (caregiver-child dyads) from 8 study locations across the 3 provinces. Families with children aged 8 to 15 years were included, aligning with the program's target demographic.

Sample Size Calculation

Quantitative Study

Using data from the first SF Program in Afghanistan [7], the total difficulty scale before and after completing the program was reported as 17.77 (SD 5.67) scores and 10.62 (SD 4.98) scores, respectively. The sample size calculation was based on a 1-group repeated-measure ANOVA [9,10] using the *wp.rmanova* package in R (R Foundation for Statistical Computing), a moderate effect size (f=0.25), a correlation of 0.5, power of 80%, and an α of .05. The required sample size was at least 45 participants to detect the effectiveness of the SF Program.

Qualitative Study

This project in Thailand included a sample size of 19 families (caregiver-child dyads), approximately 2 to 3 families per site across 8 locations in the 3 provinces. Volunteer families from each site were included. In the previous project with SF Program trainers, data saturation was achieved with interview data from 10 participants [8].

Ethical Considerations

This study was conducted following review and approval from the Institutional Ethics Committee of the Faculty of Medicine, Chiang Mai University, Chiang Mai, Thailand (ethics approval number 143/2025). All participants provided written informed consent prior to study commencement in accordance with the 1964 Declaration of Helsinki.

Data Measurement and Collection

Quantitative Study

Quantitative data were collected using the following validated instruments. The Parent and Family Adjustment Scales (PAFAS; 30 items) assessed caregivers' perceptions of their parenting practices, family functioning, and personal adjustment. The Strengths and Difficulties Questionnaire (SDQ; 25 items) assessed caregivers' perceptions of their children's emotional symptoms, conduct problems, hyperactivity, peer problems, and prosocial behavior. The Child and Youth Resilience Measure–Revised–Person Most Knowledgeable About the Child (CYRM-R-PMK; 17 items) assessed both caregivers' perceptions of their children's resilience and coping and children's self-reported resilience.

Qualitative Study

Qualitative data were gathered prospectively after the intervention through semistructured interviews guided by the reach, effectiveness, adoption, implementation, and maintenance framework [11,12]. Interviews with volunteer families were conducted individually, one family at a time. All participants were informed of the research study and provided consent with permission for audio recording. Each interview lasted approximately 40 minutes and was conducted on the same site as the workshops by research assistants who were not involved in the SF Program, supervised by NB and WJ.

Data Analysis

Quantitative Study

Descriptive statistics were used to summarize participant characteristics. The scoring key for the PAFAS indicates that higher scores reflect lower levels of parenting skills and family adjustment [13]. For the SDQ, higher scores indicate greater problems in emotional regulation, conduct, restlessness, and peer relationships; however, higher scores in the social relationships domain (prosocial behavior subscale) indicate greater strengths [14]. For the CYRM-R-PMK, higher scores reflect higher levels of child and youth resilience [15]. To examine the change in family functions in each domain of the CYRM-R-PMK, PAFAS, and SDQ over time (a week), a linear mixed-effects regression model was applied. The scores were treated as a continuous dependent variable. Time (week) was analyzed as a fixed effect. Child age, child sex, parent age, and parent sex were adjusted as potential confounders [16,17]. To account for within-subject correlation due to repeated measurements, a random intercept was specified for each participant. Model parameters were estimated using restricted maximum likelihood. Regression coefficients with corresponding 95% CIs were reported. All analyses were performed using Stata (version 17; StataCorp), and statistical significance was set at P<.05.

Qualitative Study

The qualitative interview data were analyzed using content analysis to evaluate the overall program. The datasets were uploaded into NVivo (version 12; Lumivero). Each transcript was read multiple times to aid familiarization and check the accuracy of each transcript. Two independent researchers (NB

XSL•FO
RenderX

and WJ) led the analysis. Then, preliminary results were discussed with all authors. The inductive coding was developed from patterns in the text data and adapted iteratively during analysis. The identified codes were compared, and the similarities and differences were discussed until a consensus on the emergent themes and subthemes was reached.

Results

Overview

A total of 68 families attended the SF Program across the Chiang Mai, Lamphun, and Chiang Rai provinces in 2025. Most caregivers (59/68, 86.8%) were female, with a mean age of 47.4 (SD 13.8) years. In total, 51.5% (35/68) of the children were male, and their mean age was 10.8 (SD 1.6) years.

Table 1 shows the scoring and changes in all assessment tools. Regarding the PAFAS, the results showed a significant improvement in coercive parenting (β=–0.10; *P*=.003) as the decrease in scores reflected a reduction in maladaptive behaviors. However, the analysis indicates a significant increase in scores for positive encouragement (β=0.05; *P*=.009) and parent-child relationship (β=0.28; *P*<.001); based on the inverted scoring key, these suggest a decline in positive parenting skills and relationship quality during the study period. In terms of child difficulties (evaluated using the SDQ), parents reported significant improvements, evidenced by decreases in conduct problems (β=−0.04; *P*=.002) and peer relationship problems (β=−0.04; *P*=.048). However, social relationships (a strength-based domain) showed a decrease in scores (β=−0.05), suggesting a reduction in strengths, although this was not statistically significant (*P*=.09). Similarly, children self-reported significant improvements in emotional (β=−0.05; *P*=.01) and conduct (β=−0.04; *P*=.02) behaviors. No substantial changes were observed in child resilience (CYRM-R-PMK) from either the parent or child perspectives.

[b]PAFAS: Parent and Family Adjustment Scales.

[c]SDQ: Strengths and Difficulties Questionnaire.

[d]CYRM-R-PMK: Child and Youth Resilience Measure–Revised–Person Most Knowledgeable About the Child.

The qualitative study included a total of 19 families, or caregiver-child dyads. The participating caregivers were predominantly female (17/19, 89.5%), comprising 82.4% (14/17) mothers, 11.8% (2/17) grandmothers, and 5.9% (1/17) aunts, whereas the 10.5% (2/19) male participants included 1 father and 1 foundation staff member (caregiver for a child in the foundation). The ages of these caregivers ranged from 28 to 59 years, representing early working age to middle adulthood. Regarding the children, 52.6% (10/19) were female, and 47.4% (9/19) were male, with ages ranging from 7 to 14 years. This age group corresponded primarily to the late primary and early secondary school levels, critical developmental stages (early adolescence and middle childhood) for behavior and responsibility. From the qualitative analysis, 5 themes emerged (Textbox 1).

Textbox 1. Themes of qualitative results.

- Theme 1: motivation of program engagement
- Theme 2: perceptions of learning utility
- Theme 3: goodness manifesting across household members
- Theme 4: key facilitators of success
- Theme 5: recommendations for optimization

Theme 1: Motivation of Program Engagement

The main motivation for enrolling in the program was the desire to improve parenting skills. Caregivers indicated that they wanted to learn the correct ways to teach and manage their children's behavior and understand their children better. Some caregivers also sought to resolve relationship issues at home, motivated by a desire to reduce family stress or strengthen the bond between mother and children. Other motivations for caregivers and children to participate in the program were varied, including persuasion from community and school leaders; most participants were referred by village heads, schoolteachers, or religious leaders (churches and temples). Finally, some children expressed interest in enrolling so that they could participate in the children's activities, either as a way for the latter to enjoy time with their parents or as a response to an invitation from friends:

> *I want to know what "Strong Family" means in terms of strength. I want to know how to raise children properly.* [Caregiver; family 7]
>
> *I think if we go, we will know how we can talk to children, or how can we be patient with them?* [Caregiver; family 6]
>
> *I want to improve my communication skills with my children to reduce the gap.* [Caregiver; family 1]
>
> *Mr. Boom from Tambon Administrative Organization invited me to join, so I applied.* [Caregiver; family 16]
>
> *My mom invited me to come and learn together.* [Child; family 14]

Theme 2: Perceptions of Learning Utility

Family members reported acquiring new skills and practices, including stress management techniques such as breathing exercises and somatic coping techniques (ie, tapping various points on the body) to help control anger and reduce stress. Caregivers also reported learning positive communication skills, including encouragement to use reason instead of emotions, speaking in a softer tone of voice, and actively listening to children's needs. Caregivers shared that they learned about their children's stress levels through activities such as the "stress ladder" or "thermometer," gaining insights into children's perspectives that adults might not have previously known. They also reported learning how to show affection and establish discipline appropriately without using violence, including techniques for hugging, praising, and setting rules in the home:

> *Knowing how to manage our own emotions. Knowing how to persuade children to be interested in our instructions.* [Caregiver; family 11]
>
> *I didn't listen to my child's reasoning very much. After attending the training, I was able to review and listen to my child's reasons more.* [Caregiver; family 6]
>
> *I learned about the activities. I'm guessing what level of expectation they [children] have, so they can use it to adjust.* [Caregiver; family 7]

XSL•FO
RenderX

I learn to express my stress. Then, rethink the situation or do something that helps relieve my stress. [Child; family 10]

Many things, for example, calming the mind and improving mood, such as the arm raise and lower pose, which makes the mind feel better. [Child; family 14]

Theme 3: Goodness Manifesting Across Household Members

Caregivers shared insights that they became more mindful and patient and reduced scolding, yelling, and use of violence (hitting children). Instead, they started reasoning more. Children became more responsible, enacting behaviors such as helping with household chores (washing dishes, doing laundry, and ironing), studying diligently, and doing homework independently without being told. Additionally, some children showed a decrease in aggressive behavior, such as stopping or reducing bullying at school. At the family level, it was found that the atmosphere at home improved; members became closer, talked more openly, and showed more affection toward each other such as hugging or kissing cheeks. Positive changes extended to other family members even though the spouses or other parents did not attend the training. When the parent who attended the program changed their behavior, the nonattending parent was found to drink less alcohol or act less violently and be more helpful with household chores. The younger siblings who did not attend the program often followed the positive behavior of the older sibling who did participate:

My child is easier to talk to, more confident making eye contact, and more willing to share problems. Because we don't yell or scold like before, but talk things out with reason. [Caregiver; family 16]

My child barely hugged me. But now, before he leaves, he comes to hug and kiss me. [Caregiver; family 6]

I have tried to think that our child is just like us. So, my anger has subsided. [Caregiver; family 11]

I took what I learned from the activity and told my husband. He started speaking better, so our arguments decreased. [Caregiver; family 3]

I study much harder now than I used to. I've become much more responsible.... Dad drinks less alcohol, and my younger sibling helps out more. [Child; family 14]

I do not tease on my friend anymore. [Child; family 3]

Theme 4: Key Facilitators of Success

Caregivers commented that the SF Program was a creative and fun activity and a family learning activity through shared experiences. Hearing problems from other families helped parents see their own strengths and weaknesses, not feel alone in solving problems, and know that they had clear and effective tools to improve the functioning of their family:

It helps parents learn the right way to teach their children, not just by forcing them, but by teaching them to learn through hands-on experience. [Caregiver; family 18]

If the family is strong-minded, bad external influences cannot affect our family. [Caregiver; family 11]

There was a fun game activity with my mom. [Child; family 16]

Theme 5: Recommendations for Optimization

To improve the experience of being enrolled in the SF Program and the family outcomes, caregivers stated that they would like to see activities organized regularly or continuously (eg, once a year) to prevent knowledge from fading. Participating caregivers suggested that the target group should be expanded to include more family members, such as other relatives, guardians, or siblings. Regarding the venue and time, participants shared that the activities were too short and some lacked depth. Some families suggested holding the SF Program sessions on Saturdays (as opposed to Sundays) to avoid religious obligations, and they also wanted a larger venue. They would like to see more content and training on etiquette for children, the language in the curriculum simplified, and families with specific problems selected as the target group to achieve the most noticeable changes:

I wish there were training for husbands or fathers too.... If the family training program could be done together, it would be even better. [Caregiver; family 14]

I want the program to get along with the older children who have to take care of their younger siblings.... We can help each other a lot. [Caregiver; family 5]

I want to do more activities with my mom. [Child; family 10]

Discussion

Principal Findings

This study represents the evaluation of the UNODC SF Program in Thailand. Findings suggest that while the program was highly acceptable and qualitatively perceived as beneficial, the quantitative outcomes present a complex picture of family dynamics during the transition phase of behavior change. The pattern of findings observed in this study is consistent with family systems and developmental prevention theories, which emphasize the reciprocal and dynamic nature of caregiver-child interactions. Improvements in coercive parenting alongside reductions in child conduct problems suggest that even brief changes in caregiver behavior can rapidly influence child outcomes through feedback processes within the family unit. Family skills interventions that focus on caregiver stress regulation, emotional awareness, and nonviolent discipline have been shown to interrupt maladaptive interaction cycles and promote healthier relational patterns, particularly in contexts of chronic socioeconomic stress. In this way, the SF Program operates by modifying discrete behaviors and also by strengthening relational processes that support child development and family resilience within broader ecological systems [4,18,19]. Regarding parenting and family adjustment

XSL•FO
RenderX

(PAFAS), the results showed a significant improvement in coercive parenting. However, a decline in positive parenting skills and relationship quality during the study period was observed. In terms of child difficulties (SDQ), parents reported significant improvements. However, social relationships showed a non–statistically significant reduction in strength. Similarly, children self-reported significant improvements in emotional and conduct behaviors. No significant changes were observed in child resilience (CYRM-R-PMK) from either the parent or child perspective.

These findings are consistent with the program's logic model, which emphasizes stress management and nonviolent discipline. The qualitative data strongly corroborate this as caregivers reported becoming more mindful, reducing yelling, and using reasoning instead of violence in interactions with their children. Similarly, children self-reported significant improvements in emotional and conduct behaviors, suggesting that even a short 3-week intervention can interrupt the cycle of negative interaction within the family. Additionally, our study on the early implementation of the SF Program in Thailand, which assessed feedback from the trainers of SF, also illustrated this consistent outcome of improving family function [8]. Previous literature illustrates that positive parent-child relationships, especially early and middle childhood, are associated with a favorable impact on children's behavior, avoid early-onset conduct issues, and act as a buffer against negative childhood experiences, which reduces toxic stress and improves health [20,21].

The Divergence Between Quantitative and Qualitative Findings on Relationships

An intriguing finding in our study was the discordance between the quantitative scores for parent-child relationship and positive encouragement and the qualitative narratives. While the quantitative analysis indicated a significant increase in scores, interpreted as a decline in skills based on the instrument's inverted scoring, the qualitative themes painted a contrasting picture. In the interviews, families reported improved atmospheres, increased affection (eg, hugging), and better communication. The discordance may be attributed to response shift bias [22]. Participants likely recalibrated their internal standards of positive parenting after the intervention, leading to stricter self-evaluation at the posttest compared to the pretest time point. This may also be viewed through the stages of competence development [23]. Participants moving from unconscious incompetence to conscious incompetence tend to judge their past and current behaviors more critically, resulting in lower postintervention scores despite actual skill acquisition [23]. The significant reduction in child conduct problems (SDQ) contrasted with the nonsignificant changes in resilience scores (CYRM-R-PMK). This suggests a distinction between acute behavioral symptoms, which respond rapidly to changed parenting strategies, and resilience, which is a complex, enduring trait requiring a longer duration or sustained intervention to manifest significant change [24]. Furthermore, qualitative insights revealed that caregivers reported uncertainty about their children's expectations, suggesting a period of relational recalibration and heightened sensitivity rather than deterioration. These findings underscore the necessity of the mixed methods approach adopted in this study as it captured the nuanced developmental processes that quantitative tools alone might overlook [25].

Rather than reflecting program failure, the observed response shift in self-reported parenting measures may represent a meaningful indicator of learning and engagement. Response shift occurs when participants recalibrate their internal standards or conceptual understanding following exposure to an intervention, resulting in more critical self-assessment at the posttest time point despite genuine behavioral improvement [22]. In parenting interventions, increased awareness of positive parenting norms may lead caregivers to judge their behaviors more stringently over time. This process aligns with stages of competence development, in which individuals move from unconscious to conscious incompetence before achieving mastery [23]. Qualitative reports of increased patience, reflective communication, and emotional regulation suggest that caregivers were actively internalizing program content, underscoring the value of mixed methods designs for capturing developmental processes that may not be fully reflected in standardized self-report measures alone [25].

The nonsignificant resilience findings also contrast with rapid gains reported in conflict-affected settings that implemented and evaluated SF, such as Afghanistan and Iran [26,27]. This divergence likely reflects baseline severity; populations with high trauma exposure, such as those in prior SF implementations, often have lower baselines and greater room for improvement. In the nonconflict Thai cohort, where stressors were socioeconomic rather than acute, resilience building appears to be a gradual process requiring a longer intervention duration than 3 weeks to produce statistically detectable change.

Feasibility and Cultural Adaptability

Thai communities accepted SF in the 2024 pilot, with trainers reporting that the curriculum improved family relationships and mutual understanding. The pilot's qualitative comments revealed language obstacles. Facilitators also struggled to handle intensely tough, highly emotional familial situations that spontaneously developed during group sessions. The second phase allowed for the incorporation of brief interventions and strategies for handling difficult situations relevant to the local context, as suggested from our previous phase [8]. Thus, program materials were culturally localized before phase 2. The translated texts were heavily simplified into colloquial Thai; visual assets were replaced with culturally congruent imagery (eg, Asian faces and contextually appropriate domestic scenarios); and, most importantly, the Training for the Trainers curriculum was expanded to teach trainers how to offer targeted advice and de-escalate difficult participant interactions during live facilitation. From families' perspective, this study confirms that the SF Program is feasible and culturally adaptable for Thailand. Qualitative feedback highlighted that the program was viewed as creative and fun, and the shared experience with other families helped reduce isolation. The motivation to join varied from community persuasion to a genuine desire to resolve family conflicts, underscoring the importance of community leaders (eg, village heads and teachers) in the recruitment process for such public health interventions. The research shows

XSL•FO
RenderX

that implementing SF was feasible and had a good impact on parenting skills and the mental health of families. Because the program includes sessions for both caregivers and children independently and together, SF can enhance positive characteristics and understanding of each other and help families develop new skills in coordination [27]. Families can benefit from a wide range of positive parenting activities, such as the development of good relationships, improved communication, and stress management [28].

In Myanmar, the UNODC executed a vital implementation of the SF Program in Kachin State. This open, multisite pilot feasibility and acceptability trial enrolled 100 families using a universal approach within the camps. The program demonstrated remarkable efficacy. There was an improvement across the SDQ regarding child mental health, as well as distinct enhancements in parenting practices and parent and family adjustment skills. Crucially, the data indicated that improvements were most pronounced among caregivers and children who presented with the greatest psychological and behavioral challenges at the baseline assessment, proving the intervention's high utility in acute humanitarian crises. The success of this trial directly advocated for the programmatic prioritization of family skills [29].

Barriers to Resilience and Future Directions

We observed no significant changes in child resilience (CYRM-R-PMK). Resilience is a complex, multidimensional construct that likely requires a longer duration to manifest than the immediate behavior changes observed in conduct or parenting styles. To increase resilience, the intervention needs to be continuous and comprehensive [30,31]. A 3-week intervention may plant the seeds for resilience, but measurable change may require longitudinal follow-up or sustained booster sessions, as suggested by participants who requested continuous activities to prevent knowledge from fading. Additionally, a recurring theme was the need for paternal involvement. Most participating caregivers were female (59/68, 86.8%), and participants explicitly expressed a wish for husbands or fathers to attend. The predominance of female caregivers in our study reflects traditional gender roles in rural Thai society, where child-rearing is often viewed as the maternal domain [32]. However, qualitative feedback explicitly calling for paternal involvement suggests a shifting awareness within families. Future iterations of the program should specifically target fathers through gender-sensitive recruitment strategies to maximize the systemic impact on family dynamics.

Evidence from parenting intervention research indicates that father-inclusive approaches are associated with greater and more sustained improvements in child behavior and family functioning, particularly when interventions jointly address discipline practices and emotional communication [33]. Future iterations of the SF Program may benefit from gender-sensitive recruitment strategies that actively engage fathers and other caregivers, thereby enhancing the systemic and equitable impact of family skills interventions.

Limitations

Several limitations should be noted. First, the sample size was relatively small (n=68 for quantitative assessment and n=19 for qualitative assessment) and restricted to specific provinces, limiting generalizability. Second, the absence of a control group prevents us from attributing changes solely to the SF intervention. Third, volunteer families may already possess higher motivation to improve family dynamics. The potential for response shift bias in self-reported measures suggests that future studies should include observational metrics or third-party reports to validate parenting changes. Fourth, there was a potential for recall bias in the interview session. However, we aimed to assess family behavior after the training session. Finally, the short follow-up period (12 weeks) may not capture the long-term sustainability of the skills acquired.

Conclusions

The SF Program in Thailand demonstrates strong feasibility and promising effectiveness in reducing coercive parenting, child conduct problems, and child emotional problems. While quantitative measures of relationship quality yielded mixed results, qualitative evidence strongly supports the program's value in fostering family bonding and emotional regulation. Scaling up this intervention with an emphasis on engaging fathers and providing long-term support could significantly benefit vulnerable families in the region.

Acknowledgments

The authors would like to thank the United Nations Office on Drugs and Crime, the Thai Office of the Narcotics Control Board, and the community teams for providing them with the opportunity to conduct this study. The Strong Families Program was originally developed and tested in Afghanistan owing to the generous support of the US Department of State Bureau of International Narcotics and Law Enforcement Affairs. An acknowledgment is due to the governments of France (particularly the Interministerial Mission for Combating Drugs and Addictive Behaviors), Sweden, Japan, and the Kingdom of Saudi Arabia for their support for the dissemination of the Strong Families Program worldwide. None of these donors were implicated in the research. No generative AI was used in this study. AI-assisted technologies (QuillBot) were used in the grammar check for the writing process of this manuscript.

Funding

This research was funded by the Thai Office of the Narcotics Control Board. The funders had no role in the design of this study; collection, analysis, and interpretation of the data; writing of this manuscript; or decision to publish the results. This work was partially support by Chiang Mai University.

Abstract

Background: Metabolic and bariatric surgery (MBS) is a safe and effective treatment for adolescents with severe obesity, yet no standardized lifestyle interventions exist to support sustained behavior change after MBS.

Objective: This pilot study assessed the feasibility and acceptability of TeenLyft, an online lifestyle support program for adolescents undergoing MBS, and explored preliminary clinical and safety outcomes to inform the design of a future randomized trial.

Methods: Adolescents aged 13 to 18 years were recruited from a tertiary care MBS center and enrolled in TeenLyft. The study was not powered or designed as a randomized controlled trial but rather as a pilot to guide future randomized controlled trial development. Feasibility domains included recruitment, retention, data completeness, intervention fidelity, and engagement, with predefined progression criteria of ≥80% enrollment, ≥70% retention, ≥70% data completeness, and ≥90% fidelity. Exploratory clinical and safety measures (weight, BMI, and cardiometabolic markers) were collected descriptively to confirm that participation was not associated with harm.

Results: Twenty-nine adolescents (mean age 15.9 years, SD 1.1; n=22, 75.9% female; n=13, 44.8% Hispanic; mean BMI 47.8, SD 7.3 kg/m^2) were enrolled, representing 145% of the recruitment target (n=20), with 72.4% retention at 6 months. All feasibility progression criteria were met. Descriptive trends showed expected post-MBS reductions in weight and BMI and improvements in blood pressure and hemoglobin A_{1c}, with no adverse cardiometabolic effects observed.

Conclusions: TeenLyft demonstrated high feasibility, acceptability, and safety as an adjunct to adolescent MBS care. Findings support progression to a fully powered randomized trial to evaluate long-term effectiveness and sustainability.

Introduction

Severe obesity in childhood, defined as a BMI ≥120% of the 95th percentile for age and sex or an absolute BMI >35 kg/m^2, represents the most rapidly increasing form of pediatric obesity in the United States [1]. Among adolescents aged 13 to 19 years, the prevalence of class III obesity rose from 2.1% in 2019 to 2.7% in 2023, equivalent to nearly 1 million youth (*P* value for trend <.001) [2]. Reflecting its growing impact, the American Academy of Pediatrics (AAP) has described pediatric severe obesity as "an epidemic within an epidemic" [3]. This condition contributes to elevated risks for cardiometabolic, hepatic, and renal complications, as well as diminished sleep quality and mental health, ultimately lowering health-related quality of life [3-5]. In addition, obesity in adolescence strongly predicts adult obesity and is linked to increased rates of asthma, arthritis, metabolic dysfunction, psychological distress, and at least 13 forms of cancer, contributing to reduced life expectancy [6-10].

Although behavioral lifestyle programs are foundational to pediatric obesity treatment, evidence indicates that such programs alone rarely produce sustained or clinically meaningful weight loss in adolescents with severe obesity [11-14]. In contrast, metabolic and bariatric surgery (MBS) has been shown to be both effective and safe for this population [15-18]. The 2019 AAP clinical practice statement recommends a family-centered, nonstigmatizing approach to obesity treatment that includes behavioral and lifestyle interventions, pharmacotherapy beginning around age 12 years, and MBS as an option for adolescents with severe obesity from approximately age 13 years when clinically appropriate [3,19]. To promote equitable access, the AAP further emphasizes that health care providers should inform families about surgical options and provide comprehensive preoperative and postoperative support [19]. Consistent with this guidance, national data show a steady rise in MBS use among US adolescents [2,20]. The treatment landscape for adolescent obesity continues to evolve with the approval of glucagon-like peptide-1 receptor agonists for pediatric obesity treatment. Although these medications have expanded therapeutic options for adolescents with severe obesity, MBS remains the most effective intervention for achieving substantial and sustained weight loss among appropriately selected youth [15-18]. Accordingly, there remains an ongoing need for strategies that support long-term behavioral adherence following surgery.

Despite this progress, there remains a critical gap in standardized, age-appropriate lifestyle interventions designed to accompany and sustain the behavioral changes required for long-term success after MBS [21,22]. To address this gap, we developed TeenLyft, a tailored online lifestyle support program grounded in the principles of the Diabetes Prevention Program Group Lifestyle Balance (DPP-GLB) model [23-27]. Prior DPP-GLB implementations have demonstrated improvements in BMI and cardiometabolic markers in adult populations [28]. The adaptation process for TeenLyft incorporated adolescent and caregiver input to prioritize relevant content and delivery methods. Core curriculum topics included caloric balance, nutrition, physical activity, and strategies for overcoming setbacks. Formative research also identified key motivational factors (eg, health improvement and family encouragement) and barriers (eg, fear of complications and lack of peer support) that informed the intervention design [29].

The present study reported findings from the pilot evaluation of TeenLyft among adolescent MBS recipients. Specifically, this analysis examined feasibility domains including recruitment, retention, data completeness, intervention fidelity, and participant engagement, as well as exploratory safety indicators (eg, weight, BMI, and cardiometabolic markers) to ensure the program was not associated with harm. These pilot data were collected to inform the design, progression criteria, and outcome selection for a future randomized controlled trial (RCT).

Methods

Procedures

In 2021, we were awarded funding from the Eunice Kennedy Shriver (NCT05393570) to develop and evaluate a lifestyle support program tailored for adolescents undergoing MBS. The study used a mixed methods, proof-of-concept framework to guide intervention development and pilot testing [30]. Between January 2023 and March 2024, participants were recruited from a multidisciplinary adolescent MBS clinic offering integrated psychological and nutritional care. The TeenLyft intervention content was codeveloped with input from adolescents and caregivers, drawing on principles of the DPP-GLB curriculum.

In brief, TeenLyft was a 6-month behavioral lifestyle support intervention adapted from the DPP-GLB curriculum and tailored for adolescents undergoing MBS. Guided by social cognitive theory and formative work with adolescents and caregivers, TeenLyft addressed healthy eating, physical activity, stress and emotion management, motivation, and strategies for maintaining weight-related behavior change following surgery. Content was delivered through brief online video modules distributed through YouTube (Alphabet Inc) and Facebook (Meta Platforms). A total of 86 videos were developed, including preoperative and postoperative content, with videos averaging approximately 2 to 5 minutes in length. Additional details regarding intervention development and adaptation have been published previously [29].

Ethical Considerations

Human subjects approval was obtained prior to study initiation from the University of Texas Health Science Center at Houston Institutional Review Board (IRB; HSC-SPH-19 - 0406), with the University of Texas Southwestern Medical Center and the Children's Health System of Texas participating under IRB reliance agreements. Parental consent and adolescent assent were secured in accordance with ethical standards. Although consent materials were available in English and Spanish, all participants elected to complete the study in English. All study procedures were conducted in accordance with the ethical standards of the institutional review board and the Declaration of Helsinki.

Study Design

This investigation used a quasiexperimental, prospective cohort design without a control group or random assignment, consistent

XSL•FO
RenderX

with the intent of a pilot feasibility study. The primary objective was to evaluate feasibility and acceptability outcomes including recruitment, retention, data completeness, intervention fidelity, and participant engagement to inform the design and implementation of a future fully powered RCT. Given this feasibility focus, no control group was included, and statistical analyses were descriptive in nature. Reporting followed the TREND (Transparent Reporting of Evaluations with Nonrandomized Designs) guidelines, which complement the CONSORT (Consolidated Standards of Reporting Trials) extension for pilot and feasibility trials by emphasizing transparent reporting of design, conduct, and feasibility outcomes for nonrandomized studies. Because this was a single-arm feasibility study without randomization or treatment allocation, participants, study staff, and outcome assessors were not blinded. Clinical outcome measures were obtained from routinely collected electronic health record data using standardized clinical procedures.

The study was guided by the RE-AIM (reach, effectiveness, adoption, implementation, and maintenance) framework. RE-AIM informed the selection of feasibility outcomes by focusing on participant reach (enrollment), implementation (intervention fidelity), and maintenance (retention and follow-up completion). Consistent with the goals of a pilot study, recruitment, retention, data completeness, intervention fidelity, and participant engagement were selected as primary feasibility indicators to inform progression to a future randomized trial. Exploratory clinical outcomes, including anthropometric and cardiometabolic measures, were collected to evaluate safety and identify candidate end points for future efficacy testing and are reported elsewhere [30].

Participants

Adolescents were recruited from the adolescent MBS program at Children's Health System of Texas. Eligibility criteria included (1) age 13 to 18 years, (2) meeting National Institutes of Health criteria for adolescent MBS [31], (3) ability to communicate in English or Spanish, and (4) access to study materials through the internet or a smartphone. Participants were required to complete the standard multidisciplinary clinical evaluation process for MBS, including psychological clearance. Exclusion criteria included adolescents who were not medically eligible for MBS, declined participation, or had diabetes requiring mealtime insulin. Eligibility criteria were intentionally broad to reflect real-world clinical practice and support evaluation of intervention feasibility and acceptability in a representative adolescent MBS population. All participants underwent laparoscopic sleeve gastrectomy. Roux-en-Y gastric bypass was not performed among adolescents treated within the study program during the enrollment period; therefore, no participants undergoing gastric bypass were available for inclusion.

Feasibility Measures

Feasibility outcomes were the primary end points of this pilot study. Enrollment counts (consented participants) were tracked against a target of 20 participants to assess recruitment success. Retention rates at 3- and 6-month follow-up visits were recorded to evaluate ongoing engagement. Data completeness for anthropometric and laboratory measures was used to assess the feasibility of data collection processes. Online platform analytics (YouTube and Facebook) quantified module views and average watch times during the 6-month intervention. Fidelity was monitored through delivery checklists ensuring adherence to planned content and format, and qualitative notes captured any technology-related barriers or participant burden.

Feasibility was defined a priori as achieving ≥80% of the recruitment target, ≥70% retention by 6 months, ≥70% data completeness, and ≥90% fidelity to planned intervention delivery. Outcome assessments were obtained at baseline (before MBS) and during routine clinical follow-up visits approximately 3 and 6 months following surgery. Anthropometric and cardiometabolic measures were extracted from the electronic health record as part of standard clinical care.

Exploratory Clinical and Safety Measures

Although not powered for hypothesis testing, exploratory outcomes were collected to ensure the intervention was not associated with harm and to guide end point selection for future trials. Measures included excess weight loss, BMI (raw, percentile, and *z* score), and cardiometabolic indicators (systolic and diastolic blood pressure, hemoglobin A_{1c} (HbA_{1c}), fasting glucose, and lipid profiles).

Covariates

Age, sex, race, ethnicity, and social determinants of health (SDOH) were treated as covariates. SDOH variables were derived from a standardized health system screener comprising 13 questions spanning key domains including health literacy, social support, food security, transportation access, financial stability, housing conditions, and tobacco exposure [31,32]. The screener aligns with the SDOH priority areas outlined in Healthy People 2030 [33]. Specifically, food and housing insecurity correspond to the economic stability domain; tobacco use, transportation, and access to utilities and the internet align with neighborhood and built environment; and social support and health literacy map to the social and community context and health care access and quality domains [34]. The instrument incorporates validated items, such as the hunger vital sign for food insecurity, adapted for pediatric and family use [35].

Statistical Analysis

Feasibility outcomes were summarized descriptively to assess recruitment, retention, data completeness, intervention fidelity, and participant engagement. These metrics were compared against prespecified progression criteria to determine whether the study design and procedures were suitable for a future RCT.

For exploratory purposes, descriptive analyses were used to summarize the study sample's baseline demographic, clinical, and SDOH characteristics. Continuous variables are presented as means and SDs, and categorical variables as frequencies and percentages. Changes in anthropometric and cardiometabolic indicators at 3 and 6 months after MBS were described using summary statistics and graphical trends to estimate potential effect sizes and to confirm the absence of adverse outcomes.

Although this pilot study was not powered for hypothesis testing, exploratory comparisons were conducted to examine patterns

XSL•FO
RenderX

in excess weight loss by participant characteristics. These analyses included nonparametric methods (Wilcoxon signed-rank and Fisher exact tests) and random-effects models for repeated measures to explore within-participant changes over time. Results were interpreted descriptively to guide selection of candidate outcome measures for a future trial rather than to infer efficacy. All analyses were performed using SAS (version 9.4; SAS Institute).

Results

Participant Characteristics

Summary descriptive statistics are available in Table 1.

Table . Participant characteristics before metabolic and bariatric surgery (N=29).

Descriptive characteristics	Participants
Age (y), mean (SD)	15.9 (1.1)
Age (y), n (%)	
13 - 16	19 (65.5)
17 - 18	10 (34.5)
Sex, n (%)	
Female	22 (75.9)
Male	7 (24.1)
Race and ethnicity, n (%)	
Non-Hispanic White	4 (13.8)
Non-Hispanic Black	11 (37.9)
Hispanic	13 (44.8)
Other	1 (3.4)
Weight (kg), mean (SD)	135.0 (22.1)
BMI (kg/m^2), mean (SD; range)	47.8 (7.3; 36.9 - 62.4)
Social determinants of health (positive), n (%)	
Food insecurity	4 (13.8)
Health literacy challenges	5 (17.2)
Inadequate social support	16 (55.2)
Transportation insecurity	3 (10.3)
Financial insecurity	5 (17.2)
Housing insecurity	1 (3.4)

Feasibility Outcomes

A total of 29 adolescents enrolled in TeenLyft, exceeding the planned sample of 20 and achieving 145% of the recruitment target. Retention at 6 months was 72.4% (21/29), with these 21 participants completing all scheduled follow-up assessments, clinical appointments, and laboratory measures. Most attrition reflected missed follow-up visits or inability to complete scheduled assessments rather than adverse events or concerns related to the intervention. Data completeness exceeded the 70% threshold for anthropometric and biomarker collection. The intervention was delivered with 100% fidelity to planned content and schedule. Across both online platforms (YouTube and Facebook), 86 session modules were delivered, garnering 520 total views and an average watch time of 3.38 minutes per module, indicating consistent participant engagement. No major technology barriers or participant burden were reported. Informal feedback collected during clinical visits indicated that participants found the modules easy to navigate and relevant to their postoperative needs. All feasibility progression criteria were achieved (Table 2).

XSL•FO
RenderX

Table . Feasibility outcomes and progression criteria for the TeenLyft pilot study.

Feasibility domain	Definition or metric	Prespecified target	Observed outcome	Target met?
Recruitment	Number and percent of participants enrolled compared to target (n=20 planned)	≥80% of target enrollment	29 enrolled (145% of target)	Yes
Retention	Participants completing 6-month follow-up assessments	≥70%	72.4% (21 of 29 enrolled participants); >100% (21 of planned 20 participants)	Yes
Data completeness	Participants with complete anthropometric and laboratory data through 6 months	≥70%	72.4% (21 of 29 enrolled participants); >100% (21 of planned 20 participants)	Yes
Intervention fidelity	Sessions delivered as planned (video content and schedule)	≥90%	100% delivered as planned	Yes
Participant engagement	Online module views and average watch time (YouTube and Facebook)	Descriptive only	520 total views; 3.38-min average watch time	N/A[a]
Acceptability	Informal feedback on ease of use and relevance	Qualitative assessment	Participants reported that the content was easy to navigate and relevant	Positive

[a]N/A: not applicable.

Exploratory Clinical and Safety Outcomes

Exploratory analyses of weight and cardiometabolic indicators were conducted to confirm that the intervention was not associated with harm and to estimate potential effect sizes for future studies. From baseline to 6 months after MBS, participants exhibited expected postoperative improvements, including decreases in mean weight from 136.1 (SD 28.0) kg to 95.7 (SD 15.9) kg and mean BMI from 48.3 (SD 8.3) kg/m² to 33.3 (SD 4.5) kg/m², as well as decreases in BMI percentile and *z* score. Systolic blood pressure and HbA_{1c} showed modest decreases, while diastolic blood pressure, fasting glucose, and lipid profiles remained stable (Table 3). These trends are consistent with anticipated post-MBS trajectories and suggest that participation in TeenLyft did not adversely affect expected surgical outcomes.

XSL•FO
RenderX

Table . Anthropometric and cardiometabolic biomarker change from before metabolic and bariatric surgery (MBS) to 3 and 6 months after MBS (n=21).

Outcome	Before MBS, mean (SD)	3 months after MBS, mean (SD)	6 months after MBS, mean (SD)	*P* value
Anthropometric measures				
Weight (kg)	136.1 (28.0)	110.3 (15.7)	95.7 (15.9)	<.001[a]
BMI (kg/m^2)	48.3 (8.3)	38.4 (5.6)	33.3 (4.5)	<.001
BMI percentile	99.7 (0.7)	98.5 (1.5)	96.5 (2.8)	<.001[b]
BMI *z* score	3.7 (1.2)	2.4 (0.5)	1.9 (0.4)	<.001[a]
Cardiometabolic outcomes[c]				
Systolic blood pressure (mm Hg)	125.4 (14.3)	119.2 (11.8)	117.6 (13.6)	.04
Diastolic blood pressure (mm Hg)	71.4 (10.3)	69.1 (11.2)	66.4 (8.6)	.17
Glucose (mg/dL)	99.5 (35.4)	86.3 (5.5)	88.0 (7.6)	.31
Hemoglobin A_{1c} (%)	5.7 (1.2)	4.9 (0.1)	5.1 (0.3)	.049
Total cholesterol (mg/dL)	151.2 (29.6)	0[d]	146.8 (23.7)	.59
High-density lipoprotein cholesterol (mg/dL)	39.6 (7.1)	0	43.2 (9.0)	.10
Low-density lipoprotein cholesterol (mg/dL)	90.4 (25.7)	0	86.2 (24.5)	.57
Triglycerides (mg/dL)	106.8 (49.1)	0	87.4 (21.1)	.12

[a]Multiple comparison testing using Tukey approach showed statistically significant differences between before MBS and 3 months after MBS and before MBS and 6 months after MBS, but no statistical difference between 3 and 6 months after MBS.

[b]Tukey comparison showed statistically significant differences across all time points.

[c]Lipid profiles were only collected at 6 months after MBS.

[d]Three-month lipid results are not summarized because data were available for only one participant, precluding calculation of an SD.

Exploratory Patterns in Excess Weight Loss

Although the study was not powered for hypothesis testing, exploratory comparisons were conducted to describe patterns in excess weight loss (EWL) by participant characteristics. Adolescents achieving EWL >50% tended to be older and more likely to be female compared with those with EWL ≤50%. No clear differences were observed by presurgery BMI or SDOH variables (Table 4). These patterns are provided descriptively to guide refinement of subgroup analyses and sample size planning for a future randomized trial.

XSL•FO
RenderX

Table . Comparison of excess weight loss (EWL) at 6 months among adolescents who participated in TeenLyft[a].

Variables	EWL >50% (n=9)	EWL ≤50% (n=12)	*P* value[b]
Age (y), mean (SD)	16.8 (0.7)	15.3 (1.1)	.008
Sex, n (%)			
Female	4 (44.4)	0 (0)	.006
Male	5 (55.6)	12 (100)	
Race and ethnicity, n (%)			.06
Hispanic or Latino	7 (77.8)	7 (58.3)	
Non-Hispanic Black	0 (0)	4 (33.3)	
Non-Hispanic White	2 (22.2)	0 (0)	
Other	0 (0)	1 (8.3)	
Presurgery BMI, mean (SD)	48.9 (7.6)	44.1 (5.3)	.19
Food insecurity, n (%)			.40
No	1 (33.3)	3 (100)	
Yes	2 (66.7)	0 (0)	

[a]This pilot study was not powered for hypothesis testing; all comparisons are descriptive and intended to inform outcome selection for future trials.
[b]Comparisons between groups (EWL >50% vs ≤50%) were evaluated using Wilcoxon signed-rank and Fisher exact tests, as appropriate.

Discussion

Principal Findings

This pilot study primarily evaluated the feasibility, acceptability, and safety of implementing TeenLyft, a virtual lifestyle support intervention, for adolescents undergoing MBS. The study demonstrated high recruitment, retention, and engagement, with all predefined feasibility progression criteria achieved. Recruitment feasibility was particularly strong, with enrollment exceeding the funded target (29 vs 20 participants), suggesting both high interest and successful clinic integration. This overenrollment further supports the feasibility of scaling up TeenLyft for a larger randomized trial. Participants reported the program to be accessible, relevant, and easy to use, and the intervention was delivered with full fidelity and no technological barriers. Collectively, these findings confirm that TeenLyft is a feasible and acceptable adjunct to standard adolescent MBS care and can be scaled for evaluation in a larger randomized trial.

Exploratory clinical and safety outcomes were collected to verify that participation in TeenLyft was not associated with adverse effects and to generate preliminary effect-size estimates for future research. As expected, participants experienced reductions in weight, BMI, and systolic blood pressure, along with modest improvements in HbA_{1c} over the first 6 months after surgery. Fasting glucose and lipid profiles remained stable. These trends align with previously reported outcomes for adolescent MBS cohorts [36-46], suggesting that the addition of TeenLyft did not negatively influence expected surgical results. Importantly, these findings support the safety of integrating structured behavioral support into postoperative care.

Although exploratory patterns suggested that older adolescents experienced greater EWL than younger participants and that male participants exhibited smaller reductions, the small sample size precludes firm conclusions. These patterns are consistent with prior literature indicating potential age- and sex-related differences in short-term postoperative outcomes [37-41]. Similarly, while SDOH were not strongly associated with weight outcomes, trends such as higher food insecurity among those with greater EWL highlight complex resilience factors that warrant exploration in future work [47-50].

Psychosocial outcomes were not included as formal quantitative end points in this pilot feasibility study, but psychosocial experiences have been examined within the broader TeenLyft research program [51]. Prior qualitative work identified the importance of motivation, social support, body image, weight stigma, and mental health throughout the adolescent MBS journey. Consistent with those findings, participants in the present study described perceived improvements in self-confidence, body image, motivation, and emotional well-being following surgery and participation in TeenLyft [51,52]. Future randomized trials should incorporate validated psychosocial measures to more comprehensively evaluate both benefits and potential unintended consequences of behavioral support interventions following adolescent MBS.

These feasibility findings reinforce the value of integrating digital, flexible support into adolescent MBS pathways. Online engagement through TeenLyft modules demonstrates that adolescents are willing to participate in brief, accessible, and self-directed educational content alongside clinical care. This approach may help maintain continuity of behavioral reinforcement between visits and facilitate equitable access to postoperative support, key priorities emphasized in the AAP's guidance on comprehensive obesity treatment [3,19].

Limitations and Future Directions

This study has several limitations. The small sample size, single-site design, and 6-month follow-up limit generalizability and preclude assessment of long-term outcomes. The relatively

XSL•FO
RenderX

short follow-up period is particularly important given that obesity is a chronic disease requiring long-term management. While the first 6 months following MBS are characterized by rapid weight loss and high clinical engagement, longer-term outcomes may be influenced by changes in adherence, psychosocial factors, nutritional challenges, use of antiobesity medications, or the need for additional surgical or medical interventions. Future studies should evaluate whether behavioral support interventions such as TeenLyft contribute to sustained weight management and health outcomes beyond the early postoperative period. Additionally, the absence of a control group was intentional and appropriate for a feasibility study but prevents direct evaluation of comparative effectiveness. Nonetheless, observed weight and cardiometabolic outcomes were consistent with published benchmarks for MBS in adolescents [42-47], indicating that TeenLyft did not compromise expected clinical benefits. Future studies should include a larger, more diverse sample, extend follow-up duration, and incorporate quantitative engagement metrics to assess dose-response relationships between participation and outcomes. A randomized design comparing MBS alone versus MBS plus TeenLyft will be essential to determine the program's added value beyond feasibility and safety.

Conclusions

TeenLyft demonstrated high feasibility, acceptability, and safety as a virtual adjunct to adolescent MBS care. The program achieved or exceeded all predefined feasibility criteria and showed no evidence of harm to expected postoperative outcomes. These findings provide critical groundwork for a fully powered RCT to assess the effectiveness, cost, and long-term sustainability of integrating structured, technology-based lifestyle support into standard adolescent MBS care.

This work was supported by the National Institute of Child Health and Human Development (grant R21HD105129). The funding source had no involvement in this work.

Data Availability

Deidentified data from this study are not available in a public archive. Deidentified data from this study will be made available (as allowable according to institutional review board standards) upon reasonable request by emailing the corresponding author. Analytic code used to conduct the analyses presented in this study are not available in a public archive. They may be available upon reasonable request by emailing the corresponding author. Some materials used to conduct the study are available in a public archive: ClinicalTrials.gov (NCT05393570) [53].

Authors' Contributions

SEM was responsible for the conception and design of the study and was the executive coordinator of the project. SEM and MA were responsible for the first draft. FGQ was the lead metabolic and bariatric surgeon on the project. MSM, JMF, and RB led the data coordination components, including survey operation, coordination of quantitative and qualitative data acquisition, and logistics. MAA was responsible for oversight of all qualitative study components. JMF, RB, and SN performed qualitative procedures and analysis. SEB, AW, BRC, and FGQ provided clinical expertise and oversight of all aspects of the study. SEM and FDA led all statistical analyses and table and figure design. JMF and RB led all project coordination efforts. All authors contributed to participant recruitment, data acquisition, and quality control. All authors had full access to all study data, contributed to data interpretation, critically reviewed the first draft, approved the final version, and agreed to be accountable for the work.

Conflicts of Interest

FGQ is a consultant at Ethicon Industries. All other authors declare no conflicts of interest.

Abstract

Background: Oppositional symptoms in youth are characterized by an angry or irritable mood and excessive defiance (eg, arguing), negatively impacting the mental well-being of children, adolescents, and their caregivers. Pediatric digital mental health interventions (DMHIs) that approach care from a whole-family perspective may effectively address mental health (MH) symptoms in both pediatric participants and their caregivers, though this has not been explored in the context of oppositional symptoms.

Objective: The purpose of this study was to assess oppositional symptoms in children and adolescents (aged 6 to 17 years) participating in care within the real-world conditions of a family-centered DMHI. We aimed to (1) examine baseline oppositional severity and its associations with child demographic and clinical characteristics (eg, co-occurring MH symptoms), and caregiver symptoms; (2) evaluate demographic, clinical, and engagement factors associated with oppositional symptoms during care with the DMHI; and (3) determine whether changes in oppositional symptoms during care are associated with improvements in caregivers' stress, burnout, and sleep.

Methods: Retrospective analyses included 3781 child-caregiver pairs who participated in coaching and therapy with Bend Health Inc, a family-centered, pediatric DMHI. Assessments at baseline and monthly during care measured pediatric and caregiver symptoms. Children and adolescents were grouped by oppositional severity at baseline: not significant, subclinical, and clinical. Pediatric characteristics, care type, and caregiver symptoms were compared between groups. Linear mixed-effects models assessed oppositional symptoms over months and then tested whether oppositional severity and rate of symptom improvement were associated with caregiver outcomes over time.

Results: Baseline oppositional symptoms were not significant for 51.55% (1949/3781), subclinical for 26.47% (1001/3781), and clinical for 21.98% (831/3781). More severe oppositional symptoms were associated with younger age (P<.001), nonfemale sex (P<.001), White race or ethnicity (P<.001), higher rates of MH diagnoses (all P<.001), and higher rates of co-occurring inattention, hyperactivity, depression, and sleep problems (all P<.001). Odds of elevated caregiver symptoms increased with more severe oppositional symptoms (all P<.001). At the end of care (final follow-up), oppositional symptoms improved for 73.93% (740/1001) with subclinical symptoms and 82.43% (685/831) with clinical symptoms. Symptom trajectories followed a logarithmic curve, with the greatest improvements in the first several months (P<.001). While more severe oppositional symptoms were associated with more severe caregiver stress, burnout, and sleep problems (all P<.001), monthly improvements in caregiver symptoms were significantly larger for those whose child improved more quickly (all P<.001).

Conclusions: Family-centered DMHIs may effectively address pediatric oppositional symptoms, as well as co-occurring impairments in caregiver well-being. These findings highlight the broader, system-level impact of scalable DMHIs (such as Bend) in addressing complex family MH needs. Future work should examine these effects in the long term and evaluate opposition-specific care pathways within DMHIs.

Introduction

Oppositional and defiant behaviors in children and adolescents are characterized by an angry and irritable mood, temper tantrums, frequent arguing, and vindictiveness [1]. Emerging as early as 4 years of age [2], oppositional symptoms may become persistent and severe enough to meet the criteria for oppositional defiant disorder (ODD) [3]. Estimates of the prevalence of ODD vary widely [1], with one meta-analysis of 25 studies citing a 3.3% global prevalence [4], and another study reporting a 1 in 10 lifetime prevalence in the United States [5]. These rates are even higher among clinical populations and youth in the justice system [6,7]. ODD is also a known precursor to more severe behavioral diagnoses, including conduct disorder (CD) and antisocial personality disorder [8-11], and is associated with early disciplinary issues [11], elevated risk for substance use, and higher prevalence of co-occurring mental health (MH) challenges [2,5,6,10-12]. Attention-deficit hyperactivity disorder (ADHD), a neurodevelopmental disorder characterized by disruptions in attention and executive function, is also closely linked to ODD, as these disorders share overlapping risk factors and approximately 60% of individuals with ADHD also have ODD [12].

While various environmental and genetic factors appear to be associated with ODD, maladaptive family dynamics are particularly predictive of the development of ODD [13,14]. Disruptions in the parent-child relationship, including inconsistent or reactive discipline, can inadvertently reinforce defiant behaviors, contributing to a cycle of escalating conflict and emotional strain within the family [13]. In a study of preadolescent boys (aged 8 to 13 years), negative reinforcement of oppositional and defiant behaviors was associated with a higher incidence of antisocial behavior over the following 2 years [14]. Caregivers are also negatively affected by this cycle, as persistent child behavior problems can erode caregivers' emotional regulation and capacity to implement effective strategies, further intensifying strain within the household. Caregivers of children with ODD often report high levels of stress [15-18], potentially related to their child's disciplinary issues, school difficulties, and, in some cases, involvement with the justice system [14,19]. They also experience elevated rates of sleep disturbances, anxiety, depression, and substance use [7,20-22]. Together, these patterns highlight the urgent need for accessible, family-centered interventions that can interrupt problematic dynamics and promote healthier outcomes for both children and their caregivers.

Parent management training and family-based interventions are considered effective ODD treatments for children, especially those aged 12 years and younger [1,23,24]. Children who have developed the skills to reflect on their emotions and behaviors (around 8 years of age) can have a more active role in treatment and, therefore, may also benefit from cognitive behavioral therapy (CBT) and social problem-solving skill training [24-27]. However, there is some evidence suggesting that oppositional symptoms are relatively resistant to treatment, especially those that do not involve caregiver interventions. Studies among youth have demonstrated stable or worsening symptoms over time, even as comorbid MH symptoms improve, especially in the absence of targeted intervention [7,28,29]. These challenges have led to growing interest in integrated approaches that combine accessible parent-focused training with child-directed behavioral care (eg, CBT), offering a more comprehensive, whole-family model that may be better suited to address both child symptoms and broader family dynamics.

Digital mental health interventions (DMHIs) address youth MH challenges by providing timely access to care, supporting individualized treatment plans, and integrating multiple types of care within one platform [30-33]. Studies have demonstrated the efficacy of DMHIs for many different symptom domains in children and adolescents, with most studies focusing on anxiety, depression, and stress [31,33-37]. While several coaching and therapy-based DMHIs treat child behavior problems, evaluations often overlook oppositional behaviors. Instead, many programs rely on broad checklists (eg, the pediatric symptom checklist) to measure general progress [37], or claims of symptom improvement are not peer-reviewed [38]. While one study of symptoms during coaching and therapy with a family-centered pediatric DMHI (Bend Health, Inc) used an opposition-specific measure, findings of improvement were limited by a relatively short treatment duration (<2 months) and small sample size (n=20) [28]. This study also did not address the role of co-occurring symptoms (eg, anxiety or depression) or program engagement in treatment outcomes. Further, while there is evidence that caregiver well-being improves during a child's participation with various pediatric DMHIs [21,22,39,40], and oppositional symptom reduction mediates improvements in caregiver well-being [41], the extent to which child and adolescent oppositional symptoms may associate with caregiver outcomes during care with a DMHI has not been addressed. There remains a need for a large-scale evaluation of paired youth-caregiver outcomes within the context of a real-world DMHI using a family-centered approach to address oppositional symptoms.

The purpose of this retrospective analysis was to assess oppositional symptoms in children and adolescents (aged 6 to 17 years) participating in care with a family-centered DMHI. We aimed to (1) examine baseline oppositional symptom severity and its associations with child demographic and clinical characteristics (eg, co-occurring MH symptoms), and caregiver symptoms; (2) evaluate demographic, clinical, and engagement factors associated with oppositional symptoms during care with the DMHI; and (3) determine whether changes in oppositional symptoms during care are associated with improvements in caregivers' stress, sleep, and burnout.

Methods

Study Design and Participants

This retrospective analysis included outcomes of pediatric members (aged 6 to 17 years) and their caregivers enrolled in coaching, therapy, or psychiatry programs with Bend Health Inc (Bend) between January 2023 and June 2025. The programs evaluated in this study were offered by Bend Health, Inc, through Bend Health Psychiatric Services and affiliated physician practices. Programs were delivered by MH providers in video-based sessions, and regular symptom assessments

XSL•FO
RenderX

facilitated measurement-based care. Children were not eligible to enroll in Bend programs if they were in detox for alcohol or illicit drug use, or had any of the following: active command hallucinations or severe thought disorganization, moderate-to-severe intellectual disability, neurocognitive disorder with severe memory or functioning difficulties, severe eating disorders (including BMI <18), or severe autism spectrum disorder.

Members were eligible for study inclusion if they attended at least 3 sessions by July 1, 2025 (n=6632). Members were excluded from all analyses if they did not complete valid baseline and follow-up assessments for oppositional symptoms. Caregivers were excluded if they did not complete valid baseline assessments. The final analytic sample included 3781 members and 3780 caregivers (sample sizes for specific caregiver outcomes were as follows: n=3778 for stress, n=3779 for sleep, and n=3780 for burnout).

Ethical Considerations

Before participating in care with Bend, eligible caregivers agreed to terms and conditions, and they consented to the treatment of a minor (on behalf of their child aged <18 years), agreeing to the collection of electronic data for the purposes of measurement-based care and for future data analyses. Adolescents (aged 13 to 17 years) also consented on behalf of themselves. Study participants were not recruited or compensated because all analyses were retrospective. Study procedures were approved by the Biomedical Research Alliance of New York (Study 23-12-034-1374; approved June 5, 2023).

Treatment

Treatment with Bend has been described previously [28,34]. Caregivers enroll their child (aged 6 to 17 years) in care with Bend via the online web-based portal. During enrollment, caregivers provide information including insurance or employer coverage for services and demographic information for their child (date of birth, sex at birth, race and ethnicity, and gender identity). Then, they complete a series of MH screening questions followed by fully validated assessments to measure pediatric and caregiver MH symptoms (refer to the "Assessments" section). At the end of online enrollment, the caregiver schedules an intake session with a behavioral care manager (BCM), who is responsible for coordinating the member's care between internal and external providers.

During the video-based intake session, the BCM meets with the member and their caregiver to discuss care options with Bend (eg, coaching and therapy), desired services, and insurance or employer coverage for services. Bend addresses pediatric MH challenges using a collaborative care approach, by which care may involve the following Bend providers: behavioral health coach ("coach"), licensed therapist ("therapist"), or psychiatric provider (nurse practitioner or psychiatrist). Based on the information gathered before and during intake, BCMs assign one or more of these providers to each member's care team. All members are assigned a coach. Those who have more severe or complex MH symptoms are also assigned a therapist. Psychiatric providers are also assigned to a member's care team if medication management ("psychiatry") is indicated or included in the referral. Members and their caregivers regularly participate in video-based sessions with providers on their care team, with 30-minute coaching sessions typically scheduled twice monthly and 45-minute therapy sessions once monthly, as applicable. Psychiatry sessions are as needed. BCMs continue to coordinate care and monitor progress throughout participation with Bend.

Coaching and therapy sessions follow module-based care programs designed to address specific symptom domains—for example, ADHD, problematic behaviors, anxiety, and depression—using evidence-based methods delivered over approximately 12 weeks. Care programs are designed to be age-appropriate, with age-based variations between care plans for children (aged <13 years) and adolescents (aged 13 to 17 years). Care programs deliver caregiver interventions (eg, parent training) alongside member-targeted pediatric interventions. Caregiver-targeted interventions are a significant component of care for child programs (vs adolescent programs), as well as programs addressing symptoms known to be well-managed by parent involvement (eg, problematic behaviors). Between sessions, content from care programs is reinforced through an online learning resource center (including supplemental information and activities), and caregivers can communicate with their assigned care team using asynchronous messaging. To enable measurement-based care and monitor progress, members and caregivers complete follow-up MH assessments monthly.

Assessments

Child and adolescent opposition, ADHD (inattention and hyperactivity), anxiety, depression, and sleep problems are initially screened by a series of brief MH screener questions. When symptoms are flagged by responses to the screeners (screen-in), symptoms are measured using full validated assessments. Caregivers of children and adolescents (aged <18 years) respond to questions for opposition and ADHD (inattention and hyperactivity), given the higher validity of proxy report for these symptom assessments [42]. Caregivers of children (aged <13 years) respond to the anxiety, depression, and sleep questions on behalf of their child. To facilitate accurate reporting and incorporate multiple perspectives, caregivers are instructed to complete assessments with their child, consulting on current behaviors and feelings. Adolescents (aged 13 to 17 years) self-report their own anxiety, depression, and sleep problems.

Opposition is screened by the question "...how much (or how often) has your child/teen had problematic behaviors in relation to others?" and inattention and hyperactivity are screened by the single inattention question from the *DSM-5* (*Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition*) cross-cutting measure [3]. The *DSM-5* cross-cutting measure also screens child anxiety (3 items) and depression (2 items), and sleep problems for children and adolescents (1 item) [3]. Responses to the opposition and *DSM-5* cross-cutting screeners are on a 5-item Likert-type scale from "Not at all" (score=0) to "Nearly every day" (score=4). Adolescent anxiety and depression are screened using the first 2 questions from the Generalized Anxiety Disorder 7-item (GAD-7) and Patient

XSL•FO
RenderX

Health Questionnaire 9-item (adolescent version; PHQ-9A) [43,44]. These measures are known as the Generalized Anxiety Disorder 2-item (GAD-2) and Patient Health Questionnaire 2-item (PHQ-2), respectively, and have been widely validated as screeners [45,46]. GAD-2 and PHQ-2 responses are on a 4-item Likert-type scale from "Not at all" (score=0) to "Nearly every day" (score=3).

Full assessments are completed based on responses to the MH screeners (screen-in; refer to Multimedia Appendix 1 for details). Opposition and ADHD symptoms are assessed using the Swanson Nolan and Pelham-IV (SNAP-IV), which includes 26 items total to measure opposition (items 19 - 26), inattention (items 1 - 9), and hyperactivity (items 10 - 18) symptoms. Child anxiety (10 items) and depression (11 items), and child and adolescent sleep problems (8 items) are assessed using the corresponding Patient-Reported Outcomes Measurement Information System assessments [47-49], as recommended by the *DSM-5* for these age groups. Adolescent anxiety and depression are assessed using the remaining items from the GAD-7 and PHQ-9A [43,44], respectively. For the PHQ-9A, the final item regarding suicidal ideation is not presented due to the asynchronous delivery of the assessment [50]; thus, the measure is 8 items.

Caregivers self-report their own stress, burnout, and sleep. Caregiver stress is screened by 2 items from the 18-item Parental Stress Scale (PSS) [51], which measures distress related to caregiving responsibilities and the parent-child relationship. The PSS has been validated in clinical populations [52]. Caregivers complete the remaining 16 items of the PSS if stress is flagged by screeners [51]. For continuity between member-caregiver dyads, caregivers self-report the frequency of sleep problems in the past 2 weeks using the child and adolescent screening item [3]. Caregivers rate their subjective burnout using a validated single item with a 5-item Likert-type scale from "I enjoy my work. I have no symptoms of burnout" (score=1) to "I feel completely burned out..." (score=5) [53]. Details on all full assessments are in Multimedia Appendix 1.

Measures

Member characteristics, clinical information, care engagement, and member and caregiver MH assessments were obtained from Bend's electronic health records. The following member characteristics were used: age in years (at baseline assessment), sex (male, female, and nonbinary), gender (male, female, transgender, nonbinary, and other), and ethnicity (reported categories: White, Asian, Black or African descent, Hispanic or Latino, and Other). Diagnosed conditions were reported in the following categories: ADHD (any subtype), ODD or CD, anxiety disorders (eg, generalized anxiety disorder), and major depressive disorder or dysthymia. Assessment scores were aggregated per standard procedures for each validated assessment [42-44,47-49,53]. To facilitate clear reporting, severity categories (based on score) were reported as follows: not significant for screened out (ie, full assessment not taken) and low severities, subclinical for mild severity, and clinical for moderate and severe severities.

The baseline assessment was defined as the most recent completed within the 30 days before intake (preintake). If no preintake baseline was identified, the earliest assessment completed before the first session with a coach, therapist, or psychiatrist was retained as baseline. Assessments completed before baseline were excluded. All assessments after baseline were follow-up assessments. The timing of follow-up assessments was the date of completion relative to baseline, reported in 30-day months.

The first care program assigned was summarized as "externalizing" for the ADHD, executive functioning, and problematic behaviors care programs, and all other programs (eg, anxiety and resilience) were considered not externalizing. Total sessions were calculated as the aggregate sum of attended coaching, therapy, and psychiatry sessions within the study timeframe. Session counts were also calculated for each provider type. Sessions per month were calculated as total sessions divided by the duration in care (first to last session). For members with a duration in care of less than 1 month, the denominator of this calculation was set to 1 month to prevent artificial inflation of sessions per month values. Members were categorized as having therapy or psychiatry if they attended at least one session with the corresponding provider during the study period. Members were classified as having comorbid externalizing symptoms if they had clinical inattention or hyperactivity at baseline, and comorbid internalizing symptoms if they had clinical anxiety, depression, or sleep problems at baseline. Additional details on measures are in Multimedia Appendix 1.

Statistical Analysis

Data preparation and statistical analysis were conducted using R (version 4.4.1; R Core Team) [54]. An alpha level of .05 was used for all statistical tests. Members were assigned oppositional severity groups ("group") based on baseline severity: not significant, subclinical, or clinical. Group was coded numerically (ordered by severity) for analyses, as appropriate. Assessment scores were rescaled so that 0 represented the lowest possible score, as applicable. Data preparation methods are further detailed in Multimedia Appendix 1.

Child and Adolescent Baseline Symptoms and Characteristics

The following characteristics were described by the oppositional severity group: age (in years; mean, SE), and the percentages of females and gender-sex conforming members, percent representation by ethnicity category, percentages of each type of MH diagnosis, percentages with clinical baseline MH symptoms (inattention, hyperactivity, anxiety, depression, and sleep problems). Treatment with Bend was described by the percentage of members with an externalizing symptom care program as their first care program, and those in therapy or psychiatry. Continuous variables were compared between groups using a linear model and categorical variables were compared using Cochran-Armitage trend tests with 2 levels. For ethnicity, levels were collapsed to White versus non-White; all other variables retained their original levels.

Change in Oppositional Symptoms

Full-sample duration in care was described as median (IQR) months from first to last session, and median (IQR) months

XSL•FO
RenderX

from baseline to follow-up assessments. Central trends (median [IQR]) for coaching, therapy, psychiatry, and total sessions attended were reported, with therapy and psychiatry sessions only reported for those in the corresponding type of care. Rates of oppositional symptom improvement (score decrease) and recovery (score <8) at each member's last follow-up were reported for subclinical and clinical oppositional severity groups.

Changes in oppositional symptoms over the 7 months after baseline (refer to Multimedia Appendix 1 for details) were assessed using linear mixed-effects models of score over months (from baseline assessment). To determine the most accurate functional form of time, linear (months), quadratic (months^2), and logarithmic (log [months+1]) models were evaluated. Each model included time, oppositional severity group, and their interaction as primary predictors, with a random effect of participant (member) on the intercept. Based on prior research for this program [35,55,56], we controlled for sex (female), age (in years), internalizing and externalizing symptoms, participation in an externalizing care program, therapy, psychiatry, and average sessions per month. All continuous predictors except time were mean-centered to reduce multicollinearity. Likelihood ratio tests (LRTs) identified the logarithmic model as the best fit. Adding a random effect of participant on the slope further improved model fit (P<.001) and was, therefore, retained. Finally, we evaluated potential moderators of symptom change by using LRTs to test interactions between time and each fixed effect. The final model included oppositional severity group, age (centered), externalizing care program, and psychiatry as interactions, and all other effects were retained as main effects.

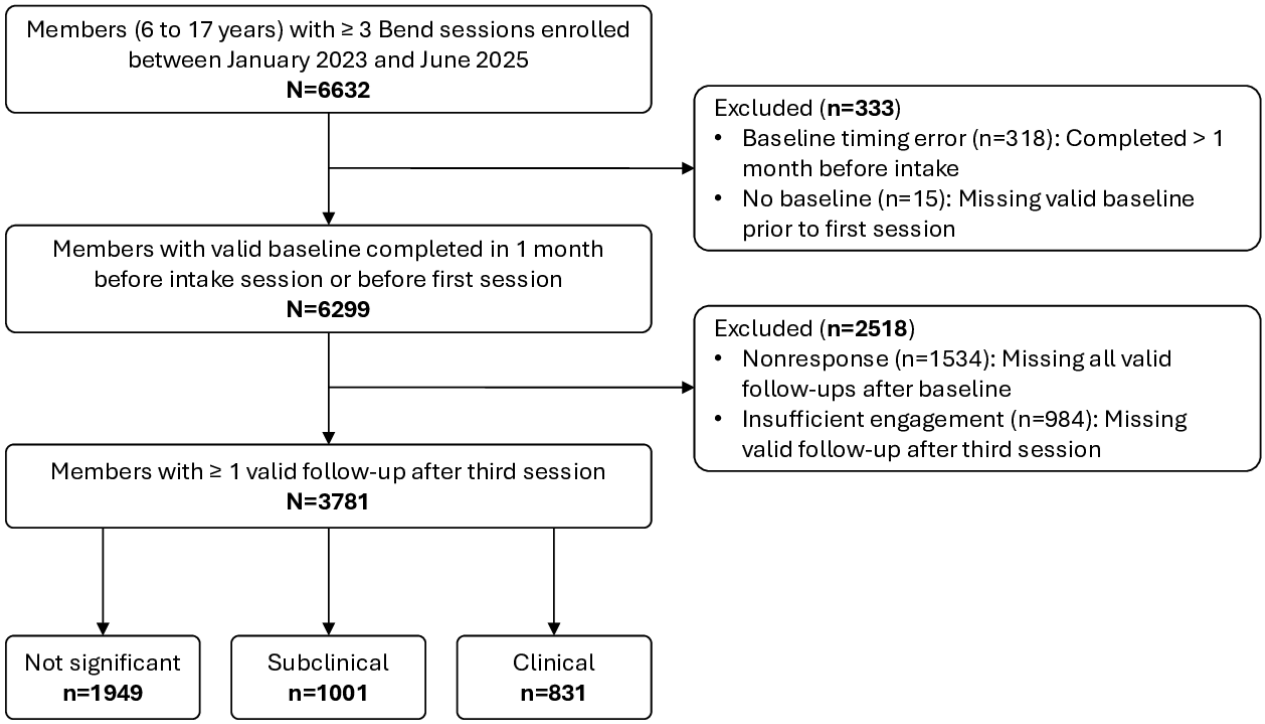
Symptom change was evaluated at the full sample's typical treatment duration using both observed and model-estimated values to characterize treatment responsiveness and to confirm model accuracy. Model-estimated scores for baseline and follow-up at 3.73 months (median follow-up) were generated for each group. Observed values were calculated using scores from baseline and final follow-up assessments completed within 4 months. Model-estimated and observed values were used to calculate the percentage reduction in symptoms from baseline to follow-up. Comprehensive details regarding oppositional model selection and refinement, including LRT results, are provided in Multimedia Appendix 1.

To prepare for caregiver symptom modeling, each child's rate of improvement at the typical treatment duration was calculated as the estimated instantaneous slope at 3.73 months. Estimates were derived from member-specific fixed and random effects to isolate the rate of improvement from other covariates. The rate was subsequently inverted and mean-centered, such that higher values represent faster improvement.

Caregiver Symptoms and Change in Oppositional Symptoms

Caregiver symptoms were first described as the percentage reporting stress, burnout, and sleep problems for all members and by oppositional severity group, with between-group differences tested by the Cochran-Armitage test. The change in likelihood for elevated caregiver symptoms associated with each 1-point increase in baseline oppositional symptom severity was expressed as odds ratios (ORs) with 95% CIs and associated P values.

For caregivers with mild-to-severe stress (n=2129), burnout (n=1680), and sleep problems (n=1760) at baseline, symptom severity (score) over the first 7 months of follow-up was assessed by linear mixed-effects models with fixed effects of time, oppositional symptom severity group, child's rate of improvement (centered), and interactions of each effect with time. A random effect of participant (member) on the intercept accounted for individual differences. Months (log-transformed) were used as the time variable because logarithmic time was identified as the best-fit functional form for all caregiver models. Additionally, a random effect of participant (member) on the slope improved model fit and was retained in all models. To further describe associations between caregiver symptoms and child oppositional symptoms, modeled caregiver symptom trajectories were plotted by oppositional severity group and child treatment response (derived from rate of improvement), including slow responders (rate=–SD), typical responders (rate=0), and fast responders (rate =+SD).



Results

Child and Adolescent Baseline Symptoms and Characteristics

Oppositional symptoms were evaluated in N=3781 children and adolescents (Figure 1). Given baseline symptoms, the oppositional severity group assignments were: 51.55% (1949/3781) not significant, 26.47% (1001/3781) subclinical, and 21.98% (831/3781) clinical (moderate: 13.96% [528/3781] and severe: 8.01% [303/3781]). Regarding characteristics (Table 1), children and adolescents with more severe symptoms tended to be younger (P<.001), were less likely to be female (P<.001), and more likely to be White (ethnicity: P<.001). They also had higher rates of ADHD, ODD, and anxiety disorder diagnosis, as well as elevated MH symptoms (except for anxiety; all P<.001). Externalizing symptom care programs and therapy were associated with more severe symptoms (all P<.001).

Change in Oppositional Symptoms

In the first 7 months, the first and last sessions were a median of 2.63 (IQR 1.33 - 4.7) months apart, and final follow-up assessments were a median of 3.73 (IQR 2.33 - 5.87) months after baseline. Members attended a median of 7 (IQR 4 - 12) sessions, corresponding with an average of 3.00 (SD 0.82) sessions per month. Members attended 6 (IQR 3 - 9) coaching sessions. Members with therapy (45.15%, 1707/3781) had a median of 3 (IQR 2 - 4) therapy sessions, and members with

XSL•FO
RenderX

psychiatry (52.53%, 1986/3781) had a median of 1 (IQR 1 - 1) psychiatry session. At the last follow-up, 73.93% (740/1001) of the subclinical oppositional severity group improved and 52.55% (526/1001) recovered, while 82.43% (685/831) of the clinical severity group improved and 23.83% (198/831) recovered.

Symptom trajectories fit a logarithmic model, characterized by rapid initial improvement during the first several months of care followed by a gradual decline in monthly improvements. Full results from the logarithmic model are reported in Table 2. In brief, oppositional symptoms improved over months (log-transformed; P<.001). Symptoms were more severe for members with greater baseline severity (P<.001), and those with comorbid externalizing symptoms (P<.001), comorbid internalizing symptoms (P=.03), an externalizing care program (P<.001), therapy (P<.001), and greater sessions per month (P=.01). Symptoms were less severe for older members (P=.004) and females (P=.006). While psychiatry was associated with less severe symptoms, the main effect did not reach statistical significance (P=.07). Rates of symptom improvement were significantly greater (faster improvement) for members with more severe baseline symptoms ($P_{interaction}$<.001). Specifically, those with clinical symptoms demonstrated rapid improvement over the first several months, whereas the subclinical group showed more gradual improvement. Scores for the not significant oppositional severity group remained largely stable (Figure 2). Rate of improvement was also significantly greater for older members ($P_{interaction}$<.001) and significantly smaller for members with psychiatry (P=.01). At the sample's typical final follow-up (3.73 months), the model-estimated aggregate symptom reduction was 27.73% for the subclinical oppositional severity group and 34.48% for the clinical oppositional severity group. These estimates were consistent with observed improvements across groups (Table 3).

Figure 2. Logarithmic trends for oppositional symptoms during care for oppositional severity groups.

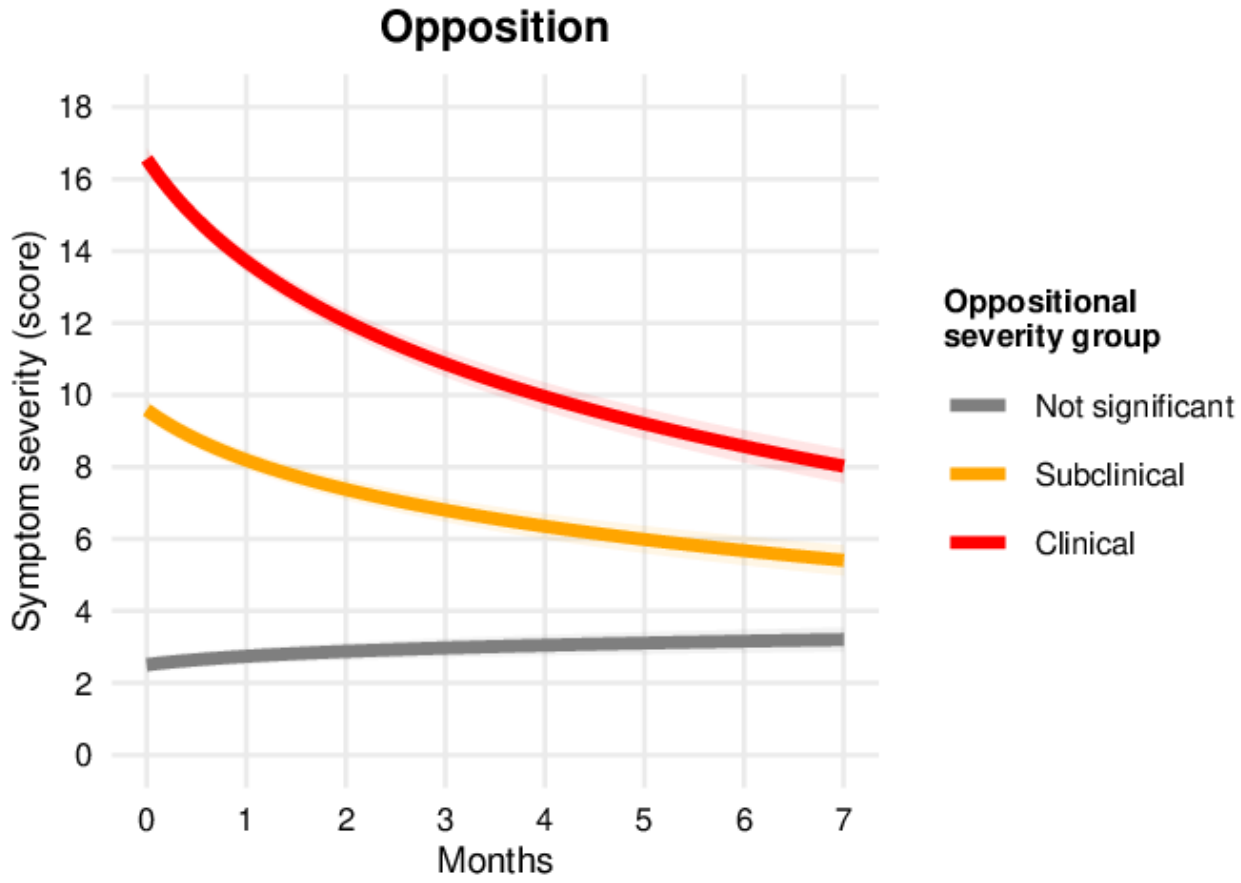

Table . Model-estimated and observed baseline and follow-up scores[a] at the median treatment duration, and the aggregate percent reduction from baseline to follow-up.

Oppositional severity group	Baseline score, mean (SD)	Follow-up score[a], mean (SD)	Percent reduction (%)
Not significant (n=1949)			
Model-estimated	2.75 (1.14)	3.45 (2.76)	−25.12
Observed	2.56 (2.65)	3.35 (3.66)	−30.84
Subclinical (n=1001)			
Model-estimated	10.14 (1.21)	7.33 (2.96)	27.73
Observed	10.41 (1.67)	7.83 (4.33)	24.77
Clinical (n=831)			
Model-estimated	17.39 (1.66)	11.39 (4.01)	34.48
Observed	17.82 (3.11)	12.34 (5.73)	30.76

[a]Model-estimated values are derived from a logarithmic mixed-effects model and calculated at the sample's median treatment duration (3.73 months). Observed values represent the last follow-up assessment completed within the first 4 months of care for each member.

Caregiver Symptoms and Change in Oppositional Symptoms

At baseline, 57.34% (2129/3713) of caregivers reported stress, 45.14% (1680/3722) reported burnout, and 47.35% (1760/3717) reported sleep problems; these rates differed across oppositional severity groups (all P<.001; Table 4). As hypothesized, greater oppositional symptom severity was associated with significantly greater odds of elevated caregiver stress (OR 1.11, 95% CI 1.10-1.12), burnout (OR 1.06, 95% CI 1.05-1.08), and sleep problems (OR 1.03, 95% CI 1.02-1.04); all P<.001. Stress was the most strongly associated with oppositional symptoms, with a 10-point change in oppositional symptom score (eg, an increase from subclinical to clinical symptoms) associated with an 184% increase in odds of caregiver stress.

XSL•FO
RenderX

Table . Caregiver symptoms reported for each oppositional severity group[a].

Symptom	Not significant, n/N (%)	Subclinical, n/N (%)	Clinical, n/N (%)	Between-group test (Z score)	*P* value
Stress	844/1914 (44.10)	634/980 (64.69)	651/819 (79.49)	17.91	<.001
Burnout	720/1919 (37.52)	469/980 (47.86)	491/823 (59.66)	10.86	<.001
Sleep problems	832/1918 (43.38)	496/978 (50.72)	432/821 (52.62)	4.87	<.001

[a]Between-group test (Cochran-Armitage tests) results identify differences in caregiver symptoms between oppositional severity groups.

All logarithmic model estimates for caregiver symptoms over months are reported in Table 5. Caregiver stress, burnout, and sleep problems decreased over months (all P<.001), following logarithmic curves with rapid improvement in the first several months and then more gradual declines later in care. More severe caregiver symptoms were associated with more severe oppositional severity (all P<.001). Faster improvement in child symptoms (greater child rate of improvement) was associated with less severe stress (P<.001) and burnout (P=.04), though this main effect was not significant for sleep (P=not significant).

Regarding the magnitude of change in caregiver symptoms over time (Figure 3), more severe oppositional symptoms were associated with larger improvement in stress ($P_{interaction}$<.001) and burnout ($P_{interaction}$=.02), whereas this effect was not observed for sleep ($P_{interaction}$=not significant). Faster improvement in child symptoms was associated with larger improvements in all caregiver symptoms over time (all P<.001), as demonstrated by diverging child treatment response trajectories for slow, typical, and fast responders (Figure 4).

Discussion

Principal Findings

This study characterized child and adolescent (aged 6 to 17 years) oppositional symptoms and associated caregiver outcomes within the real-world setting of a family-centered DMHI. Oppositional symptoms were associated with age, sex, and comorbid MH diagnoses and symptoms. Oppositional symptoms improved during DMHI participation, and those with more severe symptoms at baseline improved more rapidly. Older children and adolescents tended to improve more quickly than younger children and adolescents, and participation in psychiatry was associated with slower improvement. While more severe oppositional symptoms were associated with caregiver sleep

XSL•FO
RenderX

problems, stress, and burnout, caregivers of those with more severe oppositional symptoms reported larger improvements in their own symptoms, and caregiver improvements were more rapid for those whose child's rate of oppositional symptom improvement was greater (eg, fast responders).

This study described oppositional symptom presentation in children and adolescents receiving treatment from a DMHI and identified unique demographic factors associated with symptoms. Approximately 1 in 5 (22%) of children and adolescents had clinically elevated oppositional symptoms, yet only 10% of those with clinical symptoms had a formal diagnosis of ODD or CD. These findings are largely consistent with broader literature; while the global prevalence of ODD and CD is relatively low (<5%) [4], prevalence rates of 28% to 65% have been observed in clinical samples [6]. Boys had more severe symptoms than girls, consistent with higher ODD diagnostic rates among males [5,57,58]. Nonetheless, 45% of children and adolescents with oppositional symptoms were female. Considering that diagnostic tools and criteria are largely based on behaviors more common in males with ODD versus females (eg, physical vs relational aggression), these results demonstrate the need to monitor and address ODD in both males and females [59]. This study also found that oppositional symptoms were less severe for older children and adolescents, likely reflecting the gradual decrease in the severity of oppositional symptoms (especially defiant behaviors) from preadolescence and into adulthood [9,60]. Those with more severe oppositional symptoms were more likely to have additional MH challenges, with inattentive and hyperactivity symptoms, and ADHD and ODD diagnoses particularly prevalent among those with problematic behaviors. This finding is expected given the high rate of comorbidity between ADHD and ODD [12,58]. Notably, however, children and adolescents with oppositional symptoms varied in their individual and clinical characteristics (eg, age, sex, and co-occurring MH conditions). The DMHI evaluated here implements measurement-based care using a standardized screening protocol, potentially flagging relevant clinical symptoms in otherwise undiagnosed youth and circumventing demographic-based biases by applying the same criteria across all participants. Ultimately, findings demonstrate the value of standardized and routine screening (such as Bend) to evaluate and address oppositional behaviors in the context of pediatric DMHIs.

Though most children and adolescents did not receive care through a targeted oppositional behavior track, Bend successfully reduced oppositional symptoms in the majority (78%) of those with clinical and subclinical presentations. Symptom reductions were evident monthly, with the largest improvements in the first months of care. This finding aligns with the broader literature demonstrating that oppositional symptom improvement is associated with participation in a variety of evidence-based behavioral programs, particularly those emphasizing parenting and caregiver interventions [1,23,24,61]. With Bend, children and adolescents who started with more severe oppositional symptoms improved more quickly over the course of care, suggesting that treatment through DMHIs like Bend is effective even for participants with more serious behavior problems. Other commercial DMHIs have demonstrated improvements across a range of pediatric symptoms with coaching and therapy [37,38], and several studies have shown reduction of MH symptoms, including anxiety, depression, and ADHD, during participation with Bend [28,34,35,56]. While there is evidence that digital game-like interventions may also address ADHD and ODD in children and adolescents [62-64], this is the first rigorous study, to our knowledge, to report significant improvements in oppositional symptoms via family-centered coaching and therapy with a DMHI.

While engagement with Bend's DMHI was associated with substantial reductions in oppositional behaviors, there were differences in treatment responsiveness. First, older children and adolescents improved more quickly during care. Unlike younger children, older children and adolescents can take an active role in their treatment, potentially yielding greater gains from child-targeted interventions (eg, CBT and social problem-solving skill training) [24-27]. Additionally, because caregivers of older children are less likely to have elevated parental stress and burnout [22,40], they may be better equipped to support their child's treatment (eg, via implementation of caregiver-directed interventions) [65,66]. Children and adolescents with psychiatry, on the other hand, tended to improve less quickly than those without psychiatry. This finding suggests that children and adolescents in psychiatry were less responsive to coaching or therapy alone, such as those with more complex cases and comorbidities. Thus, it is likely that medication management in psychiatry was appropriately assigned to those requiring this higher level of care. Notably, children and adolescents with more severe symptoms had more frequent sessions during care, but sessions per month were not a significant predictor of the rate of improvement, suggesting that care intensity was scaled to meet higher clinical need. This finding contrasts with other studies reporting associations between engagement metrics and better MH outcomes, including management of behavior problems [67]. Taken together, it is likely that factors beyond engagement—including demographics, caregiver involvement, and type of care—have stronger associations with symptom progress. Overall, DMHIs that have an individually tailored and family-centered approach may be an effective solution for treating opposition, even for those with severe and complex symptom presentation.

Bend's family-centered approach provides simultaneous support to both pediatric members and their caregivers. Specifically, caregivers whose children were more responsive to care (eg, improved more quickly) also reported larger improvements in their own stress, burnout, and sleep. These findings are consistent with prior research highlighting the reciprocal relationship between child behavioral dysregulation and caregiver well-being, in which elevated externalizing symptoms in children and adolescents contribute to greater emotional strain, physiological stress, and impaired functioning in caregivers [14,15,17]. On the other hand, improvements in child behavior lessen caregiver burden and may have positive downstream effects on caregiver well-being [22,41,68]. While caregiver stress, burnout, and sleep problems improved over time in care, those supporting children with more severe

XSL•FO
RenderX

behavior problems showed the largest gains. While other studies have demonstrated improvements in caregiver symptoms during pediatric DMHI treatment [21,22,39,40]—including a recent study showing co-occurring improvements in general pediatric symptoms and caregiver symptoms—this is the first to demonstrate the sensitivity of caregiver symptoms to their child's oppositional behaviors. Indeed, reductions in caregiver stress and sleep problems are associated with better long-term outcomes, including lower incidence of MH problems, improved cardiovascular health, lower morbidity, and improved cognitive function [69-71]. These results position DMHIs such as Bend to support scalable, system-level change in pediatric and family MH care. Future studies should examine the effectiveness of opposition-specific care programs, as well as long-term outcomes of children and adolescents with symptoms of ODD.

Strengths and Limitations

This study has several notable strengths. First, this study addresses significant research questions by combining pediatric and caregiver data, contributing greatly to the clinical and scientific knowledge base on the detection and treatment of ODD symptoms. Second, by conducting primary analyses on a large sample of member-caregiver pairs (N=3781) who meaningfully engaged with the DMHI in a real-world setting for at least 3 sessions, the findings presented are more reliable and generalizable than the previous study of oppositional symptoms with Bend [28]. Third, children and adolescents with subclinical and nonsignificant symptoms were included in analyses of change. Thus, findings highlight early intervention effects and the robustness of the DMHI and analytic strategy in detecting improvements among less symptomatic children. This is notable given that such individuals typically have smaller gains and are vulnerable to potential floor effects. Additionally, by measuring symptoms over care for those with nonsignificant symptoms at baseline, we demonstrate that few children and adolescents developed new oppositional symptoms during participation with the DMHI. Thus, we can be confident that our findings reflect substantive clinical change rather than a regression to the mean. Fourth, observed and model-estimated values for oppositional symptom improvement were comparable, demonstrating the generalizability and accuracy of the results reported here. The rigor of the study is further strengthened through the use of validated, psychometrically sound measures administered at repeated time points.

Regarding limitations of the study, its retrospective and observational design precludes causal inferences; observed improvements in caregiver outcomes may reflect co-occurring changes or shared contextual factors rather than direct effects of the DMHI. Indeed, we cannot determine the directionality of the relationship between pediatric and caregiver symptom changes. The findings presented here are specific to a single DMHI (Bend) and may not generalize to other digital platforms or traditional therapy. Further research should be conducted on different DMHI tools to pinpoint particularly effective interventions and determine whether findings are generalizable. This study represents a modest follow-up period of 7 months maximum, with a typical length of participation of four months. Prior research has shown mixed long-term outcomes for ODD symptoms, with some reporting diagnostic instability (particularly in younger children) [29,72,73] and others demonstrating sustained reductions in disruptive behaviors following intervention [74]. Future studies would benefit from an extended follow-up period to evaluate the long-term stability of symptom improvements. Regarding outcome measures, the SNAP-IV is a widely used tool for assessing ODD symptoms, but it is not intended for diagnostic purposes. While multiple screening tools exist, there is no consensus on best practice [24]. Nonetheless, the cut-off scores used in this study align with standardized guidelines [75]. Another limitation is the use of caregiver report for many pediatric symptoms. Caregiver report is broadly used to measure observable behaviors (including opposition and defiance), as well as symptoms in young children (eg, aged <13 years) [47]. However, outcomes may differ significantly by informant, particularly for internalizing symptoms and symptoms or behaviors that lack cross-situational consistency (eg, behaviors present at school and not at home) [76,77]. While caregivers in this study were encouraged to seek input from their child when reporting symptoms and behaviors, future studies should use a multi-informant framework. This approach would account for potential informant discrepancies and offer a more nuanced, comprehensive assessment of child functioning. Finally, though the models controlled for several variables, residual confounding from unmeasured factors may remain. For example, the study did not evaluate several critical child and caregiver characteristics—including pediatric health outcomes, caregiver MH history and demographics, and family socioeconomic circumstances—which are likely to influence outcomes [78-81]. These additional variables should be included in future research to better elucidate their impact on family-wide MH.

Conclusions

This study provides novel evidence that oppositional symptoms in children and adolescents can improve meaningfully during participation in a family-centered DMHI, even in the absence of targeted ODD treatment. Improvements were observed across clinical and subclinical severity levels and were more pronounced in younger children and adolescents and those with more severe baseline symptoms. While engagement varied by symptom severity, session frequency did not predict the rate of improvement, suggesting that the DMHI may have effectively tailored care intensity to individual needs. Notably, improvements in caregiver outcomes were closely linked to child oppositional symptoms at baseline and during care, with greater oppositional severity and larger improvements associated with larger reductions in stress, burnout, and sleep problems. These findings underscore the promise of family-centered DMHIs (such as Bend) in delivering scalable, flexible, and family-centered care that supports both pediatric MH and caregiver well-being. Future work should examine the long-term stability of these outcomes, explore potential mechanisms of change, and evaluate how caregiver-level factors influence treatment responsiveness within digital care models.

Acknowledgments

Generative artificial intelligence was not used in the development or writing of this manuscript.

Funding

This study was fully funded by Bend Health, Inc.

Data Availability

The datasets generated or analyzed during this study are not publicly available, per Bend Health Inc's privacy policy, but are available from the corresponding author on reasonable request.

Authors' Contributions

All authors conceptualized and designed the study, and contributed to the methodology. DL-S conducted all statistical analyses. JH supervised the project. DL-S and KM drafted the manuscript, and all authors reviewed and approved the final version.

Conflicts of Interest

At the time of initial submission, DL-S, DM, and MR were employed by Bend Health, Inc (Bend), the developer of the digital intervention in this study, and JH was a paid consultant for Bend. KM is employed by JH at Fit Minded, Inc. Since the initial submission, Bend was acquired by Lyra Health. The authors' compensation and employment status are not affected by or dependent on the results of their research.

Multimedia Appendix 1
Supplemental methods, including additional information on assessments and measures, and detailed methods for data processing and statistical analyses.

Abstract

Background: The California Advancing and Innovating Medi-Cal (CalAIM) initiative supports Enhanced Care Management (ECM) for high-need pediatric populations but published evidence of the impact of ECM in pediatric populations is lacking.

Objective: We evaluated a novel multidisciplinary care model (Pair Team) for delivering ECM services, focusing on implementation and early outcomes for children and adolescents enrolled in California's Medicaid program (Medi-Cal).

Methods: We conducted a retrospective, observational cohort study of Medi-Cal-enrolled children and adolescents who enrolled in Pair Team's program between July 2022 and November 2024. Program engagement, health care engagement, and depressive symptoms were assessed using program data, electronic health records, and prescription data.

Results: The main cohort included 1294 enrollees with 12 months of follow-up data (mean age 8.9 years, 50.3% (651/1294) female, 81.8% (1058/1294) experiencing homelessness). Members averaged 2.8 interactions per month with care team members over the first 3 months and 57.1% (851/1491) were still enrolled at 12 months. In the year prior to enrollment compared to the year postenrollment, the prevalence of an asthma diagnosis increased from 7.8% to 10.0% (P=.005), outpatient visits increased 7% (rate ratio, RR=1.07, P<.001), emergency department visits decreased 9% (RR=0.91, P=.002), and antibiotic prescriptions increased 41% (RR=1.41, P=.001). For those with depressive symptoms at enrollment, mean PHQ-9 score decreased from 15.4 (SD 4.7) to 10.2 (SD 6.8) after 3 months (P<.001).

Conclusions: An innovative ECM program successfully engaged with and retained high-need pediatric Medicaid patients. Program members had higher engagement with other health care in the year following enrollment, and depressive symptoms improved. These results highlight the potential for this model to improve outcomes for the highest-need pediatric Medicaid patients.

KEYWORDS

ECM; complex needs; HRSN; Pair Team; CalAIM; Enhanced Care Management; health-related social needs; California Advancing and Innovating Medi-Cal

Introduction

Children and adolescents with complex medical and social needs, particularly those enrolled in Medicaid, face profound challenges accessing consistent, coordinated care [1]. These pediatric populations often experience fragmented health care, unmet behavioral needs, and health-related social needs such as housing instability, food insecurity, or caregiver challenges [2]. These barriers contribute to suboptimal primary and preventive care, high emergency department (ED) use, and adverse long-term outcomes [3,4]. Emerging evidence suggests that such barriers may also lead to underdiagnosis of common conditions; for example, a national analysis of Medicaid claims data found that in 17 states, asthma diagnosis rates among Medicaid-enrolled children were lower than self-reported prevalence estimates for the general pediatric population,

XSL•FO
RenderX

highlighting potential missed or delayed diagnoses in this group [5].

In response to these challenges, among others for patients of all ages, California launched the California Advancing and Innovating Medi-Cal (CalAIM) initiative in 2022 for enrollees in California's Medicaid program, Medi-Cal. A cornerstone of CalAIM is the Enhanced Care Management (ECM) benefit, which provides intensive, whole-person care coordination for Medi-Cal beneficiaries with the most complex needs [6]. Eligibility criteria extends to children and adolescents, particularly those experiencing homelessness, serious mental illness (SMI), or at risk of avoidable hospital or ED utilization [7]. Uptake among children remains low; for example, only 4040 of an estimated 95,000 eligible children in California Children's Services (CCS) were enrolled in ECM as of 2024 [8]. Implementers also report persistent challenges with referrals, outreach, and limited infrastructure to support scalable care coordination [9]. Further, despite the inclusion of pediatric populations, limited data exist on ECM implementation and outcomes in children and adolescents.

Shortly after CalAIM launched, Pair Team, a California-based medical group and ECM provider, introduced a novel multidisciplinary care model to deliver ECM services at scale [10]. The Pair Model includes two features not required by California's ECM program, both designed to address limitations in prior programs for high-need, high-cost patients. It supplements limited primary care access with telemedicine-based nurse practitioners (NPs) who support chronic disease management and care transitions, and it partners with community-based organizations (CBOs), providing training, tools, and funding to help address patients' social needs like housing, food, and transportation. This model leverages care managers from local communities, along with behavioral health clinicians, NPs, and a tech-enabled platform to coordinate services. Early evaluations have shown promising outcomes among adult participants, including increased engagement with health care and improved mental health [11]. However, children and adolescents' distinct development stages and health care utilization patterns necessitate separate evaluation of ECM's impact in younger populations.

Accordingly, in this study, we evaluate the implementation and early outcomes of Pair Team's ECM program for children and adolescent members (<18 y) enrolled in Medi-Cal. We assess both program engagement metrics and changes in trends in health care engagement pre- and postenrollment, overall and among subgroups with asthma and depressive symptoms, with the goal of demonstrating that a multidisciplinary, scalable approach to ECM can successfully engage pediatric populations. Our findings add to the evidence base on community-based care management for pediatric Medicaid populations and offer practical insights into adapting ECM to better serve youth with complex needs.

Methods

Study Design and Population

In this retrospective, observational cohort study, we analyzed metrics on program engagement, patient engagement with health care, and behavioral health outcomes for children and adolescent patients who enrolled with Pair Team. In order to enroll with Pair Team's ECM program, patients had to be Medi-Cal members who fell within at least one Population of Focus defined by the State of California: experiencing homelessness, at risk for avoidable hospital or ED utilization (with at least three ED visits and/or two inpatient stays over 12 mo), having SMI or substance use disorder, transitioning from a youth correctional facility, enrolled in CCS or CCS Whole Child Model with additional needs beyond the CCS condition, involved in child welfare, or having intellectual or developmental disabilities [7]. Patients or their families or guardians were referred to Pair Team by local CBO partners, health system partners, or Medicaid managed care plans, and Pair Team community engagement specialists contacted them with the option to enroll in Pair Team.

To be included in the current analysis, program members must have enrolled in the Pair Team ECM program between July 1, 2022, and November 30, 2024, been under 18 years of age when they enrolled, and have been continuously enrolled in the program for at least 105 days from their enrollment date. The 105-day threshold was chosen as a proxy for a 3-month timeframe because Pair care team members flag members for disenrollment if they have not responded to outreach in the first 90 days of enrollment and then make final attempts to engage before disenrolling the patient. For analyses that included data from one-year prior to and one-year postenrollment, only program members who enrolled prior to March 15, 2024, were included, to allow for at least one year of postenrollment data to be available from a Health Information Exchange (HIE) on the date of data extraction, accounting for a 6-week buffer period.

Subgroups of members with asthma at enrollment and those with depressive symptoms were also constructed, as these are among the most prevalent chronic conditions in pediatric populations, and disproportionately so for Medicaid enrollees [12-14]. Patients who had at least one provider diagnosis of asthma (an *ICD-10* code of J45.xx) and at least one prescription for a short-acting beta 2-agonist (SABA) "rescue" medication sent to a pharmacy in the year prior to enrollment were classified as having asthma at enrollment [15,16]. Depressive symptoms were defined as having a PHQ-9 (Patient Health Questionnaire-9) score >9 at enrollment, and only those at least 12 years old were included.

Program Description

The Pair Model takes an integrated approach to providing care to patients with complex medical and social needs. After patients are referred to the program, they begin with completing a comprehensive health and social needs assessment. They are then assigned to a care team, consisting of three bilingual Lead Care Managers (LCMs), an NP, a registered nurse (RN), and a Behavioral Health Care Manager (BHCM). Similar to

XSL•FO
RenderX

community health workers, the LCMs help foster deep trust-based relationships with the patients, schedule and manage appointments, coordinate with the rest of the care team and help navigate patients through the medical and social care system. The RNs provide patient education and triage urgent health needs. The BHCMs provide behavioral health interventions and referrals as needed. NPs play a notable and differentiating role in the Pair program by supplementing the limited availability of primary care in the community; this is not a standard component of ECM. They offer virtual visits, coordinate closely with patients' primary care providers, and provide follow-up after ED visits, hospital discharges, and for chronic disease management. The majority of interactions between patients and the care team are with LCMs, as the program is designed to focus on addressing social needs while scaling the impact of NPs, RNs, and BHCMs over a broad population.

Another distinguishing feature of the Pair Model is its partnership with CBOs, including homeless services organizations, shelters, and food banks, who join Pair Team's value-based network. They are provided with operational training and key tools to streamline care coordination and receive funding for services provided to patients. This partnership can help quickly address social needs of patients (such as housing, transportation needs, food and financial insecurity, etc). This level of partnership is not a standard component of ECM.

Additionally, the Pair Model utilizes a custom case management platform (Arc) that allows for in-depth care planning and automation of clinical operations, is connected to HIEs and Admission, Discharge, Transfer (ADT) feeds that provide access to outside health records and alerts when patients are in the ED or hospital, and supports seamless interactions between the care team and patients via text, phone, and email.

Additional information on the Pair Model has been previously reported [11].

Measures

Self-reported demographics and participant characteristics were collected at program enrollment in Pair Team's proprietary case management platform. Population of Focus characterizations were specific to the pediatric member rather than the parent or guardian. Program retention rates at 3, 6, and 12 months were calculated as the percent of those who had enrolled at least 3/6/12 months prior to data extraction who were continuously enrolled 3/6/12 months postenrollment.

Program engagement was measured by the number of interactions the member or their parent/guardian had with the Pair care team, including in-person, text, phone call, and email interactions. These are logged by care team members in the custom case management platform when they conclude an interaction. Only parent/guardian interactions related to their child were attributed to the pediatric member's engagement.

Health care visit data, including outpatient, ED, and inpatient visits, were extracted for one-year prior to and one-year postenrollment from an HIE that partners with the two largest national EHR networks: CommonWell Health Alliance and Carequality. Combined, these networks include over 75,000 provider sites and over 270 million patients across the country, including significant coverage in California. Provider sites include acute care centers, ambulatory care centers, hospitals, lab systems, pharmacies, and postacute care centers. Visits were classified as outpatient, ED, or inpatient according to the class coding of the original Consolidated-Clinical Document Architecture record. These visits did not include interactions with Pair NPs.

Medication prescription data for one-year prior to and one-year postenrollment were extracted from an HIE that partners with Surescripts. The Surescripts network covers 99% of US pharmacies and over 324 million patients across the US. Prescription rates were calculated based on the number of records of medications dispensed to a patient with unique combinations of dispense date, National Drug Code, and fill type (first fill or refill). Rates of antibiotic prescriptions were analyzed for the overall population; asthma medications including SABA rescue medications, oral steroids, and long-term controllers were analyzed for the asthma subgroup; and for the subgroup with depressive symptoms, tricyclic antidepressants, selective serotonin reuptake inhibitors, serotonin-norepinephrine reuptake inhibitors, norepinephrine-dopamine reuptake inhibitors, tetracyclic antidepressants, atypical antipsychotics, and mood stabilizers were analyzed.

Depressive symptoms were measured by the PHQ-9 [17], which was collected for all patients over 12 years old at program enrollment, and attempts to collect follow-up scores were made monthly for all members with a score >9 at enrollment. Analysis of change in PHQ-9 scores at 3 months was conducted for those in the depressive symptoms subgroup who had a follow-up PHQ-9 score in the window of 75 - 135 days postenrollment. When there were multiple scores reported in that window, the one closest to 90 days post-enrollment was used for analysis.

Statistical Analysis

We present descriptive statistics to describe the demographics of the study sample, as well as program retention and engagement rates. For binary outcomes (eg, the presence or absence of a diagnosis), we used McNemar's test to compare pre- and postperiod diagnosis rates within individuals.

To assess changes in visit rates and medication use, we calculated the rate ratio (RR) and corresponding 95% confidence interval (CI) using the Wald method. This method evaluates whether the rate of events (eg, provider visits or number of medications dispensed) per unit time differs significantly between two time periods, accounting for the count nature and distributional assumptions of the data, assuming that the natural logarithm of the RR is approximately normally distributed. The standard error (SE) of the log-transformed RR was calculated as the square root of the sum of the reciprocals of the event counts in each group. The 95% CI was then computed as the exponential of the log rate ratio ±1.96 times the SE.

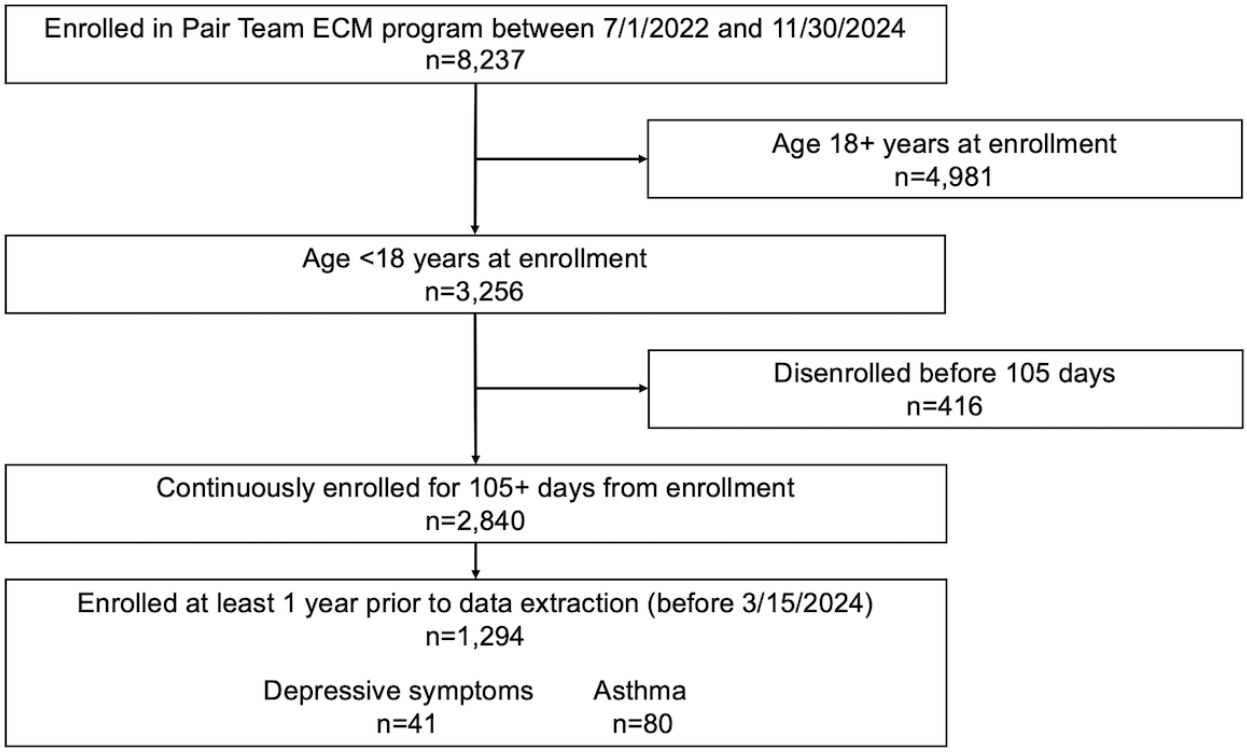
Changes in depression severity were assessed using two complementary statistical approaches applied to PHQ-9 scores collected from the same individuals at two time points. First, to evaluate changes in the mean PHQ-9 score, we used a paired t-test. Second, to assess changes in the distribution of PHQ-9

XSL•FO
RenderX

scores without assuming normality, we applied the Wilcoxon Signed-Rank test.

All tests were two-sided, and significance was defined at the .05 level. Analyses were conducted using Python, Snowflake SQL, and Microsoft Excel.

Ethical Considerations



Since the study was a secondary analysis of previously collected, deidentified data, it was deemed exempt from ethics oversight by the WCG Institutional Review Board (1-1952683-1).

Results

Sample Characteristics

A total of 3256 patients under 18 years old enrolled in the Pair Team ECM program between July 1, 2022, and November 30, 2024. Of those, 2840 (87.2%) were still enrolled 105 days later, and 1294 had 12 months of follow-up data (Figure 1). Characteristics for the cohort of 1294 are shown in Table 1. The mean age of the study participants at program enrollment was 8.9 years (SD 5.0), with 35.2% (456/1294) being 12 - 17 years old. The study population was 50.3% (651/1294) female and 46.8% (606/1294) were known to be Hispanic or Latino. The majority (81.8%, 1058/1294) were experiencing homelessness at enrollment and 25.7% (332/1294) met criteria for multiple Populations of Focus. A total of 80 (6.2%) were classified as having asthma at enrollment, and 41 had depressive symptoms at enrollment (9.0% of those 12 - 17 y old, 41/456).

Multiple PoF[e]	332 (25.7)
Individuals with an asthma diagnosis, n (%)	80 (6.2)
Individuals with depressive symptoms, n (%)	41 (3.2)[f]

[a]"Other" Race or Ethnic Group includes American Indian or Alaskan Native, Asian, Islander, and Other.

[b]Participants could be part of multiple PoFs; total does not sum to 1294 or 100%.

[c]HU: high utilizers.

[d]SMI: serious mental illness.

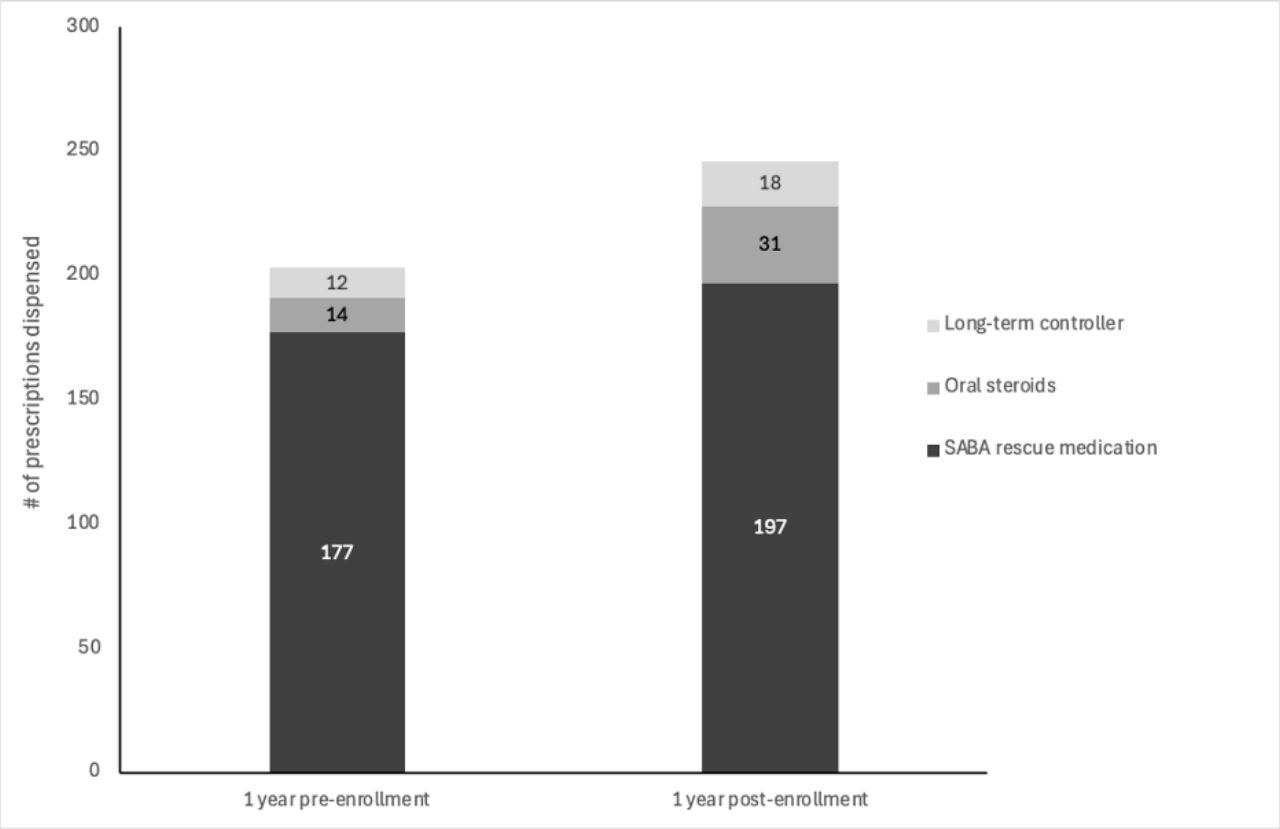
[e]PoF: Population of Focus.

[f]Only those age 12 - 17 years were eligible for this cohort; 9.0% of that age group had depressive symptoms.

Program Engagement

As noted above, retention after 3 months of enrollment was 87.2% (2840/3256). Among the 2726 pediatric patients who enrolled in the program at least 6 months prior to data extraction, retention at 6 months was 71.3% (1943/2726). Among the 1491 who enrolled at least 12 months prior to data extraction, retention at 12 months was 57.1% (851/1491). In the first 3 months after enrollment, pediatric members or their parent/guardian engaged with the Pair care team on average 2.8 times per month. Average engagement over 6 months for those enrolled at least 6 months was 2.4 interactions per month, and there were 2.2 interactions per month in the year postenrollment for those enrolled at least 12 months. Most pediatric member or parent or guardian interactions were with LCMs (84.1%, 9436/11215 in the first 3 mo, 86.8%, 24045/27692 over 12 mo). The proportion of interactions that were with RNs or NPs or BHCMs increased over time from 2.7% (307/11215) for each in the first three months to 3.3% (925/27692) with RNs or NPs and 3.2% (888/27692) with BHCMs over 12 months. The remainder of interactions were with outreach or intake specialists or other staff.

Engagement With Health Care



We assessed changes in level of engagement with health care by calculating changes in rates of asthma diagnoses, healthcare visit rates, and medication use between one-year prior to and one-year postenrollment.

The prevalence of an asthma diagnosis in the overall sample increased from 101 (7.8%) in the year prior to enrollment to 129 (10.0%) in the year post (P=.005). For those classified as having asthma at enrollment, prescriptions dispensed increased from 203 to 246, representing an increase of 21% (RR=1.21, 95% CI 1.01 - 1.46, P=.01) from the pre- to postperiod. The increasing trend was seen across medication categories (SABA

XSL•FO
RenderX

rescue medications, oral steroids, and long-term controllers) (Figure 2).

Figure 2. Asthma medication prescriptions by category.

Health care visit rates for the overall population differed between the year prior to and the year postenrollment. Outpatient visits increased from 3898 to 4159, representing a 7% increase from the pre- to postperiod (RR=1.07, 95% CI 1.02 - 1.11, *P*<.001). Conversely, acute care visits decreased. From the pre- to postperiod, ED visits decreased from 1220 to 1115, representing a decrease of 9% (RR=0.91, 95% CI 0.84 - 0.99, *P*=.002). Inpatient visits were directionally lower postenrollment, decreasing from 60 to 50, representing a decrease of 17% (RR=0.83, 95% CI 0.57 - 1.21, *P*=.14).

For the overall sample (n=1294), antibiotic prescriptions dispensed increased from 563 to 794, representing an increase of 41% (RR=1.41, 95% CI 1.27 - 1.57, *P*=.001) from the pre- to postperiod. Amoxicillin, cephalexin, azithromycin, amoxicillin and clavulanate potassium, and erythromycin were the most common prescriptions dispensed in both the pre- and postperiods.

Behavioral Health Outcomes

In the subgroup with depressive symptoms at enrollment (PHQ-9 >9) and a follow-up PHQ-9, average PHQ-9 score decreased from 15.4 (SD 4.7) at enrollment to 10.2 (SD 6.8) at 3 months follow-up (*P*<.001, n=38) (Table 2). At follow-up, 47.4% (18/38) of the subgroup had a PHQ-9 score categorized as none to mild depressive symptoms (PHQ-9 <10) (*P*<.001), and the percentage reporting any suicidal ideation decreased from 50.0% to 15.8% (*P*<.001). The proportion of patients reporting severe depressive symptoms in this subgroup decreased from 28.9% (11/38) at enrollment to 5.3% (2/38) at follow up (*P*<.001). We assessed change in mental health medication usage for the full cohort of 41 with depressive symptoms at enrollment. Prescriptions dispensed for this cohort directionally decreased from 72 to 52, representing a 28% decrease from the pre- to postperiod (RR=0.72, 95% CI 0.51 - 1.03, *P*=.17).

[b]Not applicable.

Discussion

Principal Findings

Results from this real-world study demonstrate that a multidisciplinary, scalable approach to ECM can meaningfully connect with and engage high-need pediatric Medicaid patients. The Pair Model enrolled over 3000 pediatric patients eligible for ECM in the first two years of the program, and enrollment continues to grow over time as Pair Team scales. Nearly 60% of those who enrolled were still enrolled one year later, and engagement with the care team was sustained over time, with an average of 2.2 interactions per month over the year after enrollment. These results are especially meaningful given that over 80% of those enrolled were experiencing homelessness at the time of enrollment, as populations experiencing homelessness are generally considered difficult to engage [18,19].

The differences seen in asthma diagnoses, health care visit rates, and rates of medication use in the year prior compared to the year postenrollment suggest that the Pair Model facilitates improved access to and better engagement with the healthcare system. Asthma is a condition that is more prevalent in low-income children, and diagnosis is important for proper management [13,20]. The prevalence of a record of asthma diagnosis in this study increased from 7.8% in the year prior to enrollment to 10.0% in the year postenrollment, which aligns with other estimates of asthma rates of 10% in Medicaid pediatric populations [21,22]. This suggests that asthma may have been underdiagnosed in this population prior to enrollment. It is well understood that utilizing primary and preventive care effectively leads to optimal health outcomes and lowers costs, but high ED utilization continues to be a larger problem in Medicaid populations than in commercially-insured populations [22,23]. In this study, we saw that Pair Team program members had lower ED visit rates in the year postenrollment than pre, and shifted to higher rates of outpatient visits in the post-enrollment period. This suggests that their access to and engagement with primary care improved after enrollment. While overuse of antibiotics is a problem, including in Medicaid populations, it is also important that pediatric populations have access to appropriate prescribing. The 41% increase in antibiotic prescriptions dispensed seen in this study corresponds to per-patient rates increasing from 0.4 in the year prior to enrollment to 0.6 in the year postenrollment. This brings antibiotic use in alignment with the national average of 598 prescriptions per 1000 persons for those under 18 years in 2022, and is still materially lower than prescribing rates seen in some other Medicaid populations [24,25]. However, we are unable to definitively say how much of the increase in antibiotic prescriptions is appropriate prescribing as opposed to overuse.

Adolescents experiencing complex social or medical needs, such as homelessness, are at higher risk for mental health challenges than those who are not, yet they often experience barriers to appropriate behavioral health care [19]. These barriers are multifaceted, and impacted by housing situation, access to technology, and cultural disconnection from care providers [26]. The Pair Model's emphasis on bilingual LCMs and BHCMs seeks to address these barriers by fostering trust with patients and referring them to care providers who understand the social factors they are facing. While the sample size for those with depressive symptoms in this study is not large, the improvements in PHQ-9 results are impressive and seen in parallel with directional decreases in medication usage, suggesting that the Pair Model approach of addressing social needs may have a meaningful impact on the mental health status of Medicaid adolescents.

Limitations

This study has several limitations, as is typical of observational studies conducted with real-world data. First, as a one-arm observational study, we did not have a control group, and as such we were unable to examine a cause-effect relationship. Changes in outcomes could thus be attributable in part to regression to the mean and confounding variables. Because of this, we focused our analysis on engagement metrics, and we plan to conduct controlled studies focusing on health outcomes in the future. Second, despite the large overall sample size, the asthma and depressive symptom cohort sizes were small, and as such findings for those cohorts should be interpreted cautiously. Additionally, PHQ-9 scores were only available for

XSL•FO
RenderX

a subset of the group; however, this was mitigated by the large effect size seen between baseline and follow-up scores. Lastly, we were limited to the data that was available either from the program itself or the HIE partner. While the HIE partner has extensive coverage over provider sites, it does not include every provider site and thus may miss some provider visits. Future analyses could prospectively collect data for outcomes of interest, for example pulmonary function test results for asthma, or utilize a comprehensive medical claims database in order to capture all health care utilization.

Despite these limitations, this study meaningfully strengthens the current evidence base for ECM in high-need pediatric populations. Most of the limited literature on ECM in pediatrics involves children with medical complexity rather than more broadly-defined complex needs [27]. Research on pediatric patients with complex needs is sparse, but some initial studies of care coordination for children and adolescents with special health care needs have demonstrated promising results, just as this study has [28].

Conclusions

In summary, this study demonstrates that a community-integrated, technology-enabled approach to ECM can successfully engage high-need pediatric Medicaid patients. Despite the inability to draw causal conclusions from this study, the study findings, in particular the high retention and engagement rates with the program, improvements in how patients engaged with health care, and improvements in depressive symptoms, provide an early indication that the Pair Model has the potential to improve outcomes for these patients. Future studies should examine additional health outcomes as well as include control groups in order to build a more robust evidence base evaluating this approach to ECM.

Acknowledgments

We thank Cassie Choi, RN, Pair Team Co-Founder, and Connie Kim, MS, for their development of and contributions to Pair Team's intervention.

Funding

This work was supported by the California Health Care Foundation (grant number G-34129). The funder did not have any role in study design, data collection or analysis, in writing of the report, or the decision to submit the article for publication.

Abstract

Background: Vaccination is among the most effective public health interventions to reduce childhood morbidity and mortality. Despite World Health Organization recommendations, global immunization coverage has declined in recent years, with the COVID-19 pandemic causing the largest sustained backslide in routine immunization in 3 decades. In the Democratic Republic of Congo (DRC), full immunization coverage remains below 50%, hindered by inequities, supply shortages, and financing delays. In the Kikula Health Zone, administrative reports suggest coverage exceeding 100%, yet independent surveys consistently reveal low completion and high dropout rates between Bacillus Calmette-Guérin (BCG) and measles vaccines. No previous study has specifically examined determinants of dropping out in this setting.

Objective: This study assessed the prevalence and determinants of vaccination dropout between BCG and measles vaccines among children aged 12 to 23 months in the Kikula Health Zone, Likasi, DRC.

Methods: An analytical cross-sectional survey was conducted from April 22 to May 22, 2025, using 3-stage cluster sampling to recruit 300 mother-child pairs. Vaccination status was verified using cards; for children without documentation, caregiver recall and health facility registers were used to minimize misclassification. Structured questionnaires captured sociodemographic data, child characteristics, maternal knowledge, perceptions of services, and health system access. Dropout was defined as receipt of BCG but not the measles vaccine. Bivariate associations were tested using chi-square tests, and multivariate logistic regression identified independent predictors, with robust SEs to account for clustering. Ethics approval was obtained from the University of Kinshasa School of Public Health.

Results: Among 300 children, 115 (38.3%) had dropped out between BCG and measles vaccination, while 185 (61.7%) completed the schedule. Possession of a vaccination card was the strongest predictor: children without a card had 30-fold higher odds of dropout (adjusted odds ratio 30.9, 95% CI 11.6 82.0; $P<.001$). Other factors associated with dropout in bivariate analysis included shorter residence duration (≤5 y), lower maternal education, and nonuse of child health services, although these lost significance in multivariate models. Maternal knowledge gaps were notable: 169 (56.3%) did not know their child's vaccination status and 148 (49.3%) expressed fear of side effects. Service perceptions were generally positive (participants reporting good reception: n=294, 98%), but 108 (36%) experienced waiting times of 1 to 2 hours. The exclusion of undocumented children likely led to underestimation of dropout prevalence.

Conclusions: Vaccination dropout between BCG and measles remains high in the Kikula Health Zone, driven primarily by lack of vaccination cards and maternal knowledge gaps. Administrative coverage data (>100%) mask substantial dropout, underscoring the need for improved documentation, maternal education, and targeted outreach. Programmatic implications include strengthening card management, deploying mobile vaccination units, and enhancing community reminders. Findings highlight the importance of addressing both demand and supply-side barriers to reduce dropout and improve equity in immunization coverage in the DRC.

KEYWORDS

vaccination dropout; immunization coverage; child health; Democratic Republic of Congo; maternal knowledge; health system factors

Introduction

Vaccination is recognized as one of the most effective public health strategies for reducing childhood morbidity and mortality. The World Health Organization (WHO) recommends that all children receive vaccines against tuberculosis, diphtheria, pertussis, tetanus, poliomyelitis, measles, hepatitis B, *Haemophilus influenzae* type b, pneumococcus, rubella, and yellow fever before their first birthday in endemic countries [1]. Despite these recommendations, global immunization coverage has declined in recent years. Between 2019 and 2021, coverage with the third dose of the diphtheria-tetanus-pertussis vaccine (DTP3) fell from 86% to 81%, leaving 25 million children without full protection, including 18.2 million "zero-dose" children [2]. Similar declines were observed for the first dose of measles-containing vaccine (MCV1), which dropped from 85% to 81% [2]. The COVID-19 pandemic contributed to the largest sustained backslide in routine immunization in 3 decades, disproportionately affecting low- and middle-income countries [3,4].

In the WHO African Region, progress has remained limited. DTP3 coverage increased only modestly from 70% to 74% between 2013 and 2019, while MCV1 coverage declined slightly from 70% to 69% [1]. Updated assessments from 2023 confirm that Africa continues to account for the highest proportion of zero-dose children globally, driven by persistent inequities, service disruptions, and health system weaknesses [5]. In 2021, an estimated 25 million African children were not vaccinated, including 734,000 in the Democratic Republic of Congo (DRC) [1].

In the DRC, the Expanded Programme on Immunization aims to achieve ≥90% coverage for all antigens. The national immunization schedule recommends Bacillus Calmette-Guérin (BCG) at birth; 3 doses of DTP-HepB-Hib at 6, 10, and 14 weeks; and oral polio vaccine, pneumococcal conjugate vaccine, rotavirus vaccine, and measles vaccine at 9 months. However, full immunization coverage remains below 50%. The 2017 - 2018 Multiple Indicator Cluster Survey (MICS) reported that only 35% of children aged 12 to 23 months were fully vaccinated, while 20% had received no vaccines at all [6,7]. Financing delays, recurrent supply shortages, and geographic inequities are major contributors to low coverage [6,7]. Recent multicountry analyses in sub-Saharan Africa confirm that maternal education, socioeconomic status, and health system accessibility remain key determinants of incomplete immunization [8,9].

In the Haut-Katanga province, administrative data suggested that 88.3% of children aged 0 to 11 months were fully vaccinated in 2021. Yet, vaccine-preventable diseases persisted: 1347 measles cases (including 349 zero-dose children), 34 acute flaccid paralysis cases, 101 meningitis cases, 14 neonatal tetanus cases, and 74 cholera cases. The BCG-measles dropout rate reached 11.4%, representing 35,680 children who did not complete their vaccination schedule [10]. In the Kikula Health Zone, administrative coverage was reported at 113.7% in 2022, but independent surveys conducted between 2020 and 2023 revealed that only 26% of children aged 12 to 23 months were fully vaccinated, with no improvement over time [11]. The validated dropout rate in this study was 38.3%, replacing earlier contextual estimates of 26% from prior surveys. This discrepancy between administrative data and field-based findings highlights structural, social, and health system factors influencing vaccination dropout.

No prior study has specifically examined the determinants of vaccination dropout in the Kikula Health Zone, representing a critical evidence gap. Guided by the Andersen behavioral model of health service use [8] and the health belief model [9], which emphasize predisposing, enabling, and perception-related factors influencing health-seeking behavior, this study aimed to assess the prevalence and determinants of vaccination dropout between BCG and measles vaccines among children aged 12 to 23 months in the Kikula Health Zone, Likasi, DRC.

Methods

Study Design and Setting

We conducted an analytical cross-sectional study between April 22 and May 22, 2025, in the Kikula Health Zone, Likasi city, Haut-Katanga province, DRC. The zone includes urban and periurban health areas with heterogeneous access to immunization services. The Kikula Health Zone was purposively selected due to its high vaccination dropout rate and the documented discrepancy between administrative coverage (>100%) and survey-based estimates (<30%).

Study Population and Eligibility Criteria

The study population consisted of children aged 12 to 23 months and their mothers or primary caregivers.

Inclusion Criteria

The inclusion criteria were as follows: children aged 12 to 23 months at the time of the survey, residence in the health zone for 6 months or more, presence of the mother or primary caregiver, and provision of written informed consent.

Exclusion Criteria

The exclusion criteria were as follows: refusal to participate and children severely ill and unable to participate.

Determination of Vaccination Status

Children with vaccination cards had their immunization status verified directly by card inspection, and children without vaccination cards were also included in this study. For these cases, vaccination status was determined through caregiver recall and, when available, verification against health facility registers. This approach ensured that all eligible children were represented in the study while acknowledging the potential for misclassification bias.

XSL•FO
RenderX

Sampling Strategy

A three-stage cluster sampling technique was applied. First, health areas were selected using probability proportional to size. Second, streets or segments were randomly selected within each health area, with support from community health workers. Third, households were visited systematically (eg, every third household). If multiple eligible children were present, the youngest was selected to reduce recall bias. This approach ensured representativeness despite the absence of a complete sampling frame.

Sample Size

Sample size was calculated using the Schwartz formula for cross-sectional studies:

$$n=Z^2\times P(1-P)/d^2$$

where Z=1.96 (95% confidence level), P=.26 (dropout prevalence from previous Kikula surveys), and Cohen d=0.05 (margin of error).

The initial estimate (n=296) was adjusted for a design effect of 1.5 and rounded to 300 to account for nonresponse. In total, 322 households were approached, and 300 households completed the survey (response rate 93.2%).

Recruitment Procedures

Prior to data collection, meetings were held with health zone authorities and community health workers to explain objectives and obtain authorization. Investigators introduced themselves at households, explained the study, verified eligibility, and obtained written consent. Noneligible or refusing households were skipped according to the sampling interval. Daily supervision ensured adherence to protocol and data quality.

Data Collection

Data were collected using a structured, interviewer-administered questionnaire covering maternal sociodemographic characteristics (eg, age, education, marital status, occupation, religion, and duration of residence), child characteristics (eg, age, sex, and birth order), vaccination status verified by card, maternal knowledge (eg, importance of vaccination, schedule, vaccine-preventable diseases, and adverse events following immunization), perceptions of services (eg, reception, waiting time, information, vaccine availability, and perceived cost), and health system factors (eg, distance to the facility, participation in campaigns, and possession of a vaccination card).

The questionnaire was pretested in a nonselected health area. Investigators received training on ethical procedures, standardized administration, and card verification. Daily debriefings corrected inconsistencies.

Variables

Dependent Variable

The dependent variable was vaccination dropout, defined as receipt of BCG but not the measles vaccine. The dropout rate was calculated using the following formula: dropout rate=(number of children who received BCG but not measles)/(number of children who received BCG)×100. The variable was coded as 1=dropout and 0=no dropout.

Independent Variables

The independent variables included the following: maternal sociodemographics (eg, age ≤25 y vs >25 y; education: none, primary, secondary, and higher; marital status; occupation; religion; and residence ≤5 y vs >5 y), child characteristics (eg, age, sex, and birth order), maternal knowledge (eg, importance, schedule, diseases, and adverse events), perceptions of services (eg, reception, waiting time, information, availability, and cost), and health system factors (eg, distance: <5 km, 5 - 10 km, and >10 km; campaign exposure; and possession of a vaccination card).

Thresholds

Thresholds (eg, maternal age, distance, and residence duration) were based on regional literature and operational practice.

Operational Definitions of Key Variables

Use of child health services was defined as whether the child had ever been taken to a health facility for preventive or curative services (eg, growth monitoring, vaccination, and consultation) in the past 12 months. “Yes” indicated the child received at least one service, while “no” indicated the child had not received any service.

Recourse to child health service was defined as the caregiver’s reported use of formal health services for the child (eg, vaccination sessions, consultations, and campaigns). “Yes” indicated that the caregiver reported attending at least one vaccination session or campaign, while “no” indicated that the caregiver reported never attending.

Possession of a vaccination card was defined as whether the caregiver could present the child’s vaccination card at the time of the survey. “Yes” indicated that the card was available and verified, while “no” indicated that the card was absent, and vaccination status was determined by recall and/or registers.

Data Management

Incomplete questionnaires and cases without vaccination cards were excluded. Data were entered into Epi Info (version 7.2.3.1; Centers for Disease Control and Prevention), cleaned, and then exported to SPSS (version 26; IBM Corp). A partial double-entry procedure was performed to check consistency. No imputation was applied.

Statistical Analysis

Data analysis was performed using descriptive, bivariate, and multivariate analyses:

- Descriptive analysis—frequencies and percentages were calculated for categorical variables, while means or medians were calculated for continuous variables.
- Bivariate analysis—chi-square or Fisher exact tests were used. Variables with P<.20 were retained for multivariate analysis.
- Multivariate analysis—logistic regression was performed to estimate adjusted odds ratios (AORs) with 95% CIs. Robust SEs were used to account for clustering.

XSL•FO
RenderX

Multicollinearity was assessed using variance inflation factors. Statistical significance was set at $P<.05$.

Extremely high AORs (eg, >30,000) were interpreted cautiously, acknowledging that they likely reflect sparse data or near-perfect separation rather than precise effect sizes.

Ethical Considerations

Ethics approval was obtained from the Ethics Committee of the School of Public Health, University of Kinshasa (ESP/CE/099/2023). Written informed consent was obtained from all participants. Data were anonymized, coded, and securely stored. No financial incentives were provided to participants, in accordance with national guidelines. The study results represented conservative estimates due to the exclusion of children without documented vaccination records.

Results

Overview

Among 300 children aged 12 to 23 months included in the survey, 115 (38.3%) had dropped out between BCG and measles vaccination, while 185 (61.7%) completed the schedule (Table 1).

Most respondents were mothers (295/300, 98.3%). Children were evenly distributed by sex (male: n=153, 51% and female: n=147, 49%). Most mothers were aged 25 years or younger (n=247, 82.3%). Education levels were no schooling (n=7, 2.3%), primary (n=70, 23.3%), secondary (n=207, 69.0%), and higher or university (n=16, 5.3%). Most mothers were housewives (n=230, 76.7%) and married (n=259, 86.3%). Protestant affiliation was predominant (n=164, 54.7%). Duration of residence exceeded 5 years for 174 (58%) mothers, while 126 (42%) had lived in the area for 5 years or less (Table 2).

Vaccination was considered "very important" by 103 (34.3%) of 300 mothers and "important" by 178 (59.3%) mothers. Only 8 (2.7%) mothers considered vaccination "not important." More than half (n=169, 56.3%) of the mothers did not know their child's vaccination status. Knowledge of adverse events following immunization was reported by 158 (52.7%) mothers, while 142 (47.3%) were unaware. Fear of side effects was expressed by 148 (49.3%) mothers. Nearly all households (n=289, 96.3%) reported low income. Concerns about vaccine safety for the child were expressed by 195 (65%) mothers (Table 3).

Reception at health facilities was rated "good" by 294 (98%) of 300 respondents. Waiting times were less than 1 hour for 163 (54.3%) respondents, 1 to 2 hours for 108 (36%), and more than 2 hours for 29 (9.7%). Information about vaccines was received by 234 (78%) respondents. Distance to facilities was less than 5 km for 223 (74.3%) respondents, 5 to 10 km for 54

Bivariate Analysis

Dropout was significantly associated with the following: duration of residence of 5 years or less (odds ratio [OR] 1.95, 95% CI 1.20 - 3.72; *P*=.007), nonuse of child health services (OR 4.62, 95% CI 2.20 - 9.01; *P*<.001), absence of a vaccination card (OR 44.19, 95% CI 18.98 - 102.91; *P*<.001), and lower maternal education (no schooling: OR 42.0, 95% CI 3.16 - 556.5; *P*=.001 and primary education: OR 7.41, 95% CI 1.56 - 35.1; *P*=.001; Table 5).

[a]OR: odds ratio.

[b]OR=1 indicates the reference category.

[c]Not applicable.

[d]ind: indeterminate (n value too small).

Multivariate Analysis

After adjustment, only possession of a vaccination card remained a strong independent predictor of dropout: children without a vaccination card had an AOR of 30.9 (95% CI 11.6 - 82.0; *P*<.001).

Extremely high ORs and wide CIs should be interpreted with caution. These values likely reflect sparse data or near-perfect separation rather than precise effect sizes.

Discussion

Principal Findings

This analytic cross-sectional study of 300 mother-child pairs in the Kikula Health Zone revealed a validated vaccination dropout rate of 38.3% between BCG and measles vaccines. Possession of a child health or vaccination card was the strongest independent predictor of dropout, with children lacking cards having nearly 31-fold higher odds of incomplete immunization. Other factors, such as shorter duration of residence, lower maternal education, and nonuse of child health services, were significant in bivariate analysis but lost significance in multivariate models, likely due to collinearity and small subgroup sizes. These findings highlight the critical role of vaccination documentation and maternal knowledge in sustaining immunization coverage.

Interpretation in Light of Theoretical Frameworks

The results can be interpreted through the Andersen behavioral model of health service use [8] and the health belief model [9]. Predisposing factors such as maternal age, education, and marital status influenced vaccination behavior, although their effects diminished after adjustment. Enabling factors such as possession of a vaccination card and use of child health services facilitated completion of the schedule. Perceptions such as maternal fear of side effects and lack of knowledge about vaccination status contributed to dropout. These frameworks underscore that

XSL•FO
RenderX

vaccination behavior is shaped not only by access but also by perceptions and enabling resources.

Perceptions—maternal fear of side effects and lack of knowledge about vaccination status contributed to dropout.

Comparison With Previous Studies

Our findings are consistent with national surveys (MICS 2017 - 2018) reporting low full immunization coverage (<40%) and high dropout rates in the DRC [6,7]. These findings highlight the critical role of vaccination documentation and maternal knowledge in sustaining immunization coverage. Similar associations between maternal education, vaccination documentation, and service use have been reported in other sub-Saharan African settings [5]. However, the magnitude of the effect of card possession in this study (AOR 30.9, 95% CI 11.6 - 82.0) is unusually high, reflecting the centrality of documentation in this context. Extremely high ORs and wide CIs should be interpreted with caution, as they likely reflect sparse data or near-perfect separation rather than precise effect sizes [12].

Implications for Programmatic Action

The discrepancy between administrative coverage (>100%) and survey-based findings (38.3% dropout) highlights systemic weaknesses in data quality [10,11]. Inflated administrative reports may delay corrective measures and misguide resource allocation. Programmatic priorities should include strengthening card management and documentation systems, enhancing maternal education and awareness of vaccination schedules, deploying mobile vaccination units to reach underserved households, improving communication strategies to address fears of side effects, and integrating dropout monitoring into routine supervision to ensure timely corrective action.

These measures are essential to reduce dropout and improve equity in immunization coverage in the DRC.

Limitations

This study has several limitations. First, the inclusion of children without vaccination cards, whose immunization status was determined through caregiver recall and health facility registers, may have introduced misclassification bias. Therefore, the results should be interpreted with caution, although this approach allowed for a more comprehensive assessment of dropout determinants. Second, the cross-sectional design precludes causal inference. Third, some variables lost statistical significance in multivariate analysis due to collinearity and small subgroup sizes, which limits precision. Fourth, the study was conducted in a single health zone, which may restrict generalizability to other settings. Despite these limitations, the sample size (N=300) was adequate to detect significant associations, and the findings provide valuable insights for programmatic action.

Conclusions

Vaccination dropout between BCG and measles remains high in the Kikula Health Zone, driven primarily by lack of documentation and maternal knowledge gaps. Addressing these barriers through improved card management, maternal education, and targeted outreach is critical to strengthening immunization coverage. The findings underscore the need for accurate data, integrated monitoring, and context-adapted interventions to reduce dropout and achieve equitable immunization in the DRC.

Acknowledgments

The authors thank the Kikula Health Zone management team, the heads of health areas, and the community health workers for their support during data collection. The authors also acknowledge the mothers and caregivers who generously participated in this study. All authors declared that they had insufficient or no funding to support open access publication of this manuscript, including from affiliated organizations or institutions, funding agencies, or other organizations. JMIR Publications provided article processing fee (APF) support for the publication of this paper.

Abstract

Background: Despite progress in childhood vaccination, many children in low- and middle-income countries, including Ethiopia, remain unvaccinated, presenting a significant public health challenge. The Immunization Agenda 2030 (IA2030) seeks to halve the number of unvaccinated children by identifying at-risk populations, but effective strategies are limited. This study leverages machine learning (ML) to identify Ethiopian children aged 12-35 months who are at higher risk of being zero dose (ZD). By analyzing demographic, socioeconomic, and health care access data, the study developed predictive models using different algorithms. The findings aim to inform targeted interventions, ultimately improving vaccination coverage and health outcomes.

Objective: This study aimed to develop an ML model to predict ZD children and to identify the most influential predictors of ZD in Ethiopia.

Methods: We examined how well the predictive algorithms can characterize a child at risk of being ZD based on predictor variables sourced from the recent National Immunization Evaluation Survey data. We applied supervised ML algorithms with the survey datasets, which included 13,666 children aged 12-35 months. Model performance was assessed using accuracy, area under the curve, precision, recall, and F_1-score. We applied Shapley Additive analysis to identify the most important predictors.

Results: The Light Gradient Boosting Machine (LGBM), Random Forest, Extreme Gradient Boosting (XGBoost), and AdaBoost classifiers effectively identified most ZD children as being at high risk. Among these, LGBM demonstrated the best performance, achieving an accuracy of 93%, an area under the curve of 97%, a precision of 94%, and a recall of 91%. The most significant features impacting the model included poor perception of vaccination benefits, lack of antenatal care utilization, distance from immunization services, and absence of maternal tetanus toxoid vaccinations.

Conclusions: The developed ML models effectively predict children at risk of being ZD, with the LGBM model showing the best performance. This model can guide targeted interventions to reduce ZD prevalence and address vaccination inequities. Key predictors include access to immunization sites, maternal health service utilization, and perceptions of immunization benefits. By focusing on these vulnerable groups, public health efforts can tackle disparities in vaccination coverage. Enhancing maternal care, raising caregiver awareness, and improving immunization access through outreach can significantly reduce the number of ZD children.

Introduction

Child immunization is a cornerstone of public health, essential for safeguarding against life-threatening diseases and promoting the health of future generations [1]. Globally, significant advancements have been made in immunization programs, resulting in higher coverage rates [2] and a corresponding decline in vaccine-preventable disease [3]. However, as of 2023,

XSL•FO
RenderX

approximately 14.5 million children worldwide didn't receive the first dose of diphtheria, tetanus, and pertussis (DTP1) containing vaccines [4], a widely used indicator of access to immunization services [5]. This high number of zero-dose (ZD) children continues to be a pressing issue, intensifying health inequalities and heightening the likelihood of vaccine-preventable disease outbreaks [6]. These ZD children remain at high risk, creating considerable hurdles for public health efforts [7-9].

In a substantial portion of these ZD children, about 60% are concentrated in 10 low- and middle-income countries, including Ethiopia. Despite notable achievements in improving immunization coverage in Ethiopia, the country ranks third globally for ZD children, following Nigeria and India, accounting for 6% of the world's total [4].

Addressing the issue of children at risk of becoming ZD has emerged as a priority on both national and global agendas [10]. The Immunization Agenda 2030 (IA2030), endorsed by the World Health Assembly in November 2020, aims to reduce the number of ZD children by ensuring that every child is reached by 2030 [5]. However, effectively identifying and reaching these at-risk children poses significant operational challenges, and little is known about what strategies perform best.

Research in Ethiopia has identified various predictors of low immunization uptake, including low education levels and low wealth index [11-13], rural residence [12,14], limited access to health services [15,16], lack of antenatal care (ANC) and postnatal care (PNC) [13,15-18], home deliveries [13-16], absence of maternal tetanus toxoid (TT) vaccination [12,19], and poor caregiver knowledge [16]. However, there is a lack of evidence regarding how well these factors predict ZD status specifically and which factors are most relevant for optimal prediction.

Recent advancements in data science, coupled with available routine immunization data, present new opportunities to identify and reach at-risk children at both subnational and individual levels. Developing a robust algorithm to predict ZD children based on a set of variables could provide a valuable foundation for tailored interventions. Machine learning (ML) has emerged as a transformative tool in public health research particularly suited for this task which can capture complex relationships and interactions between variables [20-22]. Unlike traditional statistical methods that rely on predefined hypotheses, ML models can autonomously identify patterns and relationships within large datasets by learning from data rather than making prior assumptions [20,23,24]. This capability is particularly useful for multifactorial issues such as immunization uptake [25].

Using rule-based ML models can uncover hidden relationships among determinants of ZD children in large datasets, often represented through "if-then" statements that illustrate connections between variables [26]. This application of ML bridges the gap between theoretical research and practical applications, leading to advancements in the health care field [27].

This study aims to use ML algorithms to predict which Ethiopian children aged 12-35 months are at higher risk of being ZD and assess the predictive capabilities of the developed models. Findings from this study may provide actionable insights for policy makers and immunization program actors, informing the development of targeted strategies to effectively identify and reach those most at-risk children.

Methods

Study Design

The data for this study were sourced from the recent National Immunization Evaluation Survey in Ethiopia, which provides nationwide representation [28]. The survey included 11 regions and the 2 city administrations. A 2-stage stratified cluster sampling technique was used to select participants. The first stage is the enumeration areas (EAs), which served as clusters, randomly chosen with an urban-rural stratification approach, and the second stage is households within each EA. Sampling frames were prepared for each region and city administrations by the Ethiopian Statistical Services. The number of EAs required per region and city administration was determined based on the size within the stratum (study regions) and proportion of the Ethiopia population living in urban and rural areas (21.4% urban and 78.6% rural). A total of 468 EAs were randomly selected, comprising 100 from urban areas and 368 from rural regions, resulting in a total sample size of approximately 13,666 households with children aged 12 - 35 months.

We extracted information on immunization status for children aged 12 - 35 months. The vaccination status of children was assessed using 3 sources of information: caregiver reports, home-based vaccination cards, and facility-based records, following World Health Organization guidelines [29]. If a mother or a caregiver presented an immunization card, the child's vaccination status was assessed from that card. In cases where the card was unavailable, data collectors were instructed to verify the information at the nearest health facility if the caregiver reported that their child had been vaccinated. The mother's or caregiver's self-reports were considered only when neither the immunization card nor the facility records were available.

Using the operational definition set by Gavi, we defined a variable ZD status for each child, which is set to 1 if the child did not receive the first dose of the diphtheria, TTs, and pertussis-containing vaccine (DPT1), and set 0 otherwise [30,31].

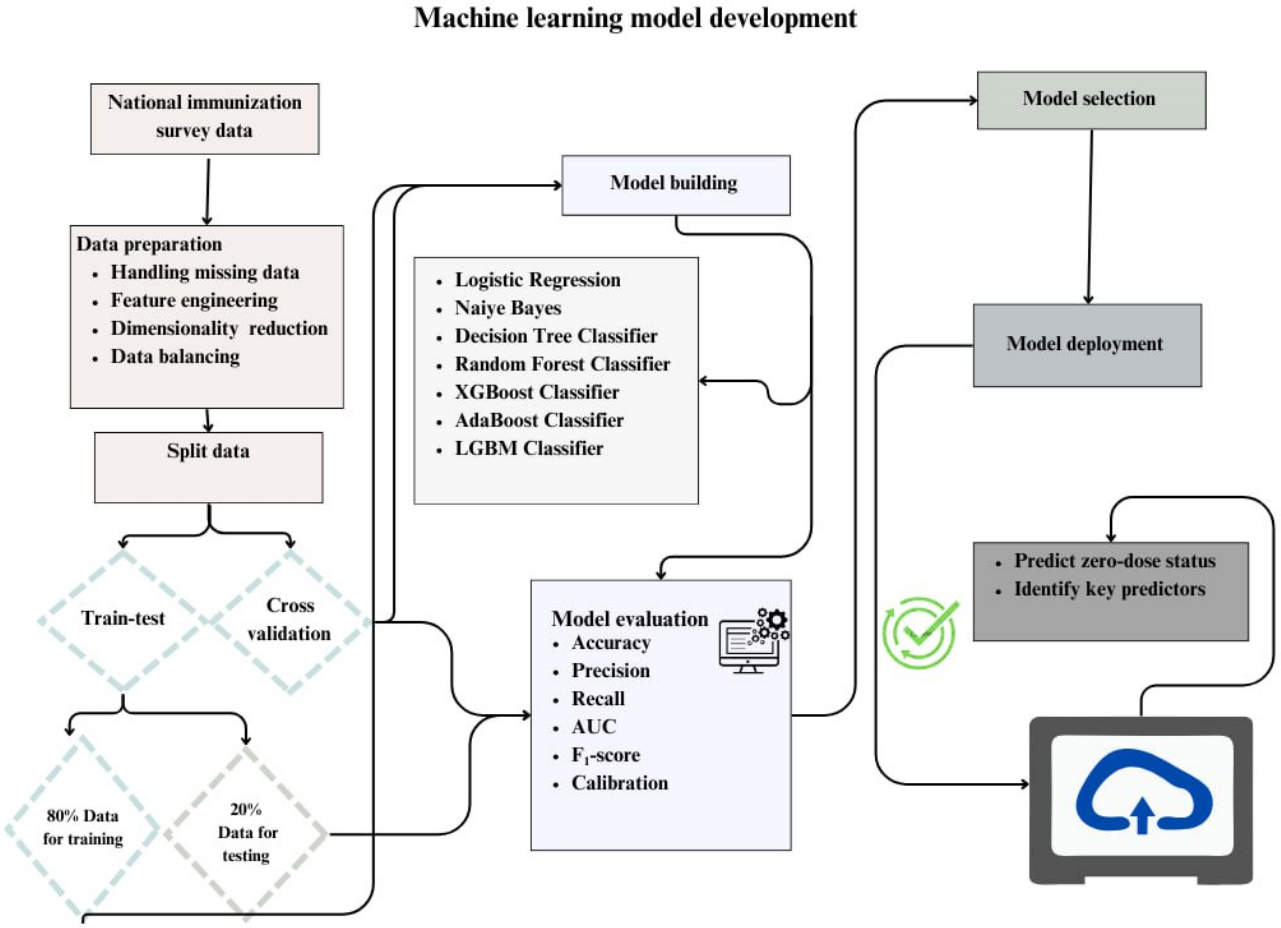
We included a set of predictor variables or features to capture characteristics that have been associated with ZD status (Table 1). The factors influencing the outcome of interest are grouped into 3 groups: socioeconomic and demographic variables, health service utilization, and perceptions and attitudes. The first group of socioeconomic and demographic variables encompasses individual, household, and community-level characteristics that may affect the outcome of interest. The health service utilization represents the access to and use of various health care services, which can impact immunization status. The third category

XSL•FO
RenderX

focuses on the perceptions or attitudes that individuals or caregivers have toward the benefits of immunization. All the 3 categories of the variables gathered during the survey.

Table . The predictor variables used for analysis were extracted from the recent National Immunization Evaluation Survey in Ethiopia, 2023.

Category	Description	Response/type of data
Socioeconomic and demographic factor		
Residency	Type of living arrangement	Categorical (urban and rural)
Region	Geographic area of residence	Nominal (eg, Afar, Amhara...)
Religion	Cultural beliefs influencing health behaviors	Nominal or categorical (orthodox, Muslim, protestant, and others)
Marital status	Relationship status of the mother or the caregiver	Categorical (married and living together, married, married but not living together, and not in marital union)
Mother's or caregiver's educational status	Level of formal education attained	Categorical (no, primary, secondary, and higher education)
Occupation of mothers or caregivers	Employment status and type of work	Nominal categorical data
Birth order	Position of a child in relation to their siblings within a family	Categorical (first, second, third, and fourth and above)
Wealth index	Measures economic status	Categorical (poor, middle, and rich)
Health service utilization		
ANC[a] follow-up	History of ANC visits for the index child	Categorical (Yes/No)
History of maternal tetanus diphtheria vaccine	Previous vaccinations received	Categorical (Yes/No)
Distance to immunization site	Perceived impact of distance on immunization access	Categorical ("big problem," "not a problem")
Place of delivery	Location where the child was born	Categorical (Home/Facility)
Postnatal care	Follow-up care received after childbirth	Categorical (Yes/No)
Perceptions and attitudes		
Mother's or caregiver's perceived benefits on immunization	Beliefs regarding the advantages of vaccination	Was Likert (categorized into poor or good)
Trust in health care provider	The belief of mothers or caregivers on the services provided	Categorized into poor or good



[a]ANC: antenatal care.

Data Preprocessing and Transformation

We implemented several preprocessing steps to enhance model performance. First, we addressed missing values in the independent variables using the k-nearest neighbor approach. We then transformed categorical variables into numerical format through one-hot encoding, which is essential for preparing data for ML models. To standardize feature ranges, we applied minimum-maximum scaling and mean normalization, ensuring comparability among features (Figure 1).

XSL•FO
RenderX

Figure 1. Data preparation and analysis steps for zero-dose children prediction. AUC: area under the curve; LGBM: Light Gradient Boosting Machine.

We conducted sampling weight as instance weights during the training process for all algorithms. This was done by using the sample_weight parameter in the model's fitting functions, which adjusts the influence of each observation based on its probability of selection.

Next, we conducted a correlation analysis to identify and remove highly correlated features, thereby reducing multicollinearity and enhancing model robustness. Our correlation matrix showed a strong relation between parity and birth order (Figure 2), leading us to compute mutual information scores for each variable (Figure 3). This analysis highlighted ANC utilization and TT vaccination as significant predictors, while features such as marital status were excluded due to their minimal information value. Consequently, we retained birth order and omitted parity based on their scores.

XSL•FO
RenderX

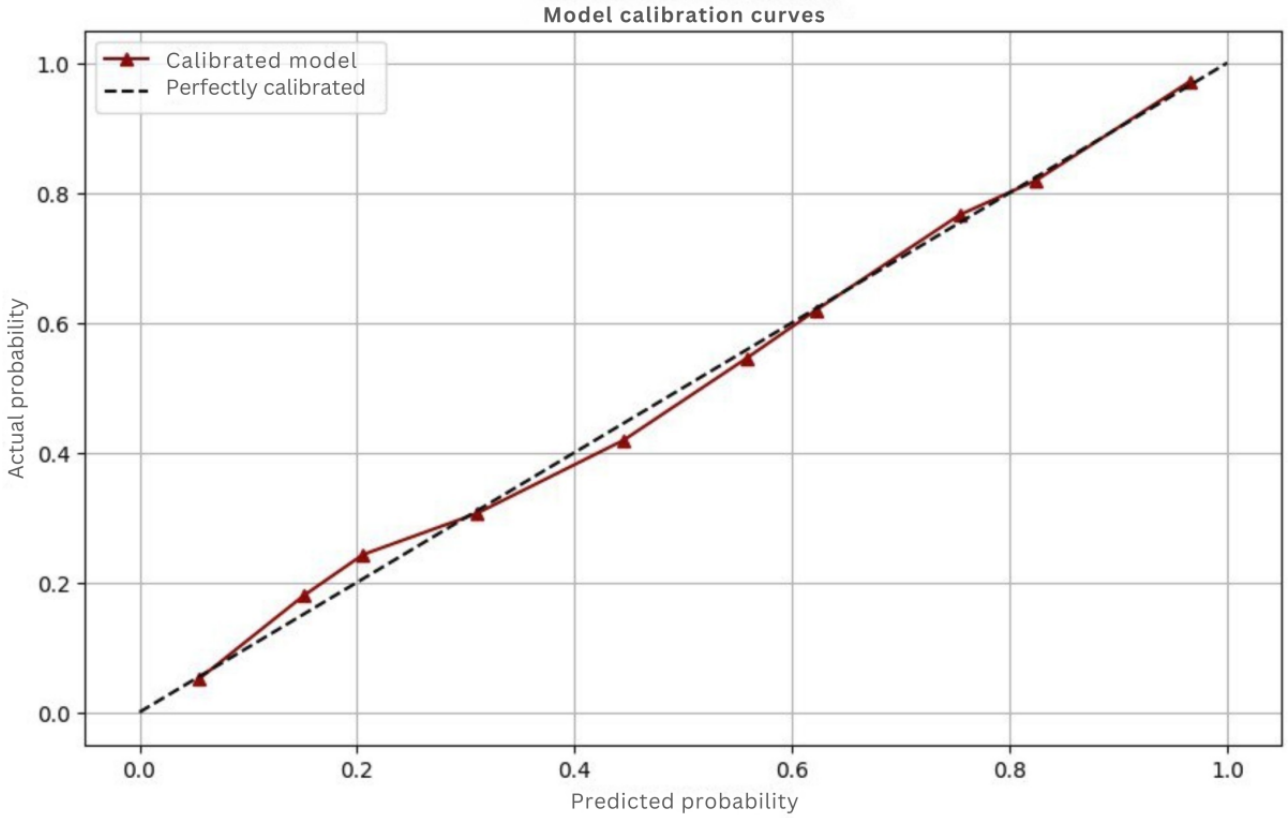
For dimensionality reduction, we used Forward Selection, Backward Elimination, and Recursive Feature Elimination methods. We opted for Recursive Feature Elimination due to its effectiveness in identifying the most significant predictors while simplifying the dataset. To address class imbalance, we applied the Synthetic Minority Oversampling Technique, which balanced the dataset from an initial skew of 82% majority and 18% minority to an equal distribution. This balancing supports the development of robust predictive models and mitigates bias toward the majority class (Multimedia Appendix 1).

Model Development

After the preprocessing, we split the dataset into 80% for training and 20% for testing (Figure 1). To avoid overfitting and underfitting, we applied 10-fold cross-validation, dividing the data into 10-folds and using one for validation while training on the others. The final performance is averaged across all folds.

The outcome variable, known as the class, is a binary variable indicating ZD status. A ZD status of 1 denotes a ZD child, while 0 indicates a non-ZD child. We applied supervised learning algorithms to develop a model from the training data to accurately predict this outcome in the test data.

Given the categorical nature of the outcome variable, we used 7 classical classification algorithms: AdaBoost Classifier [32], Logistic Regression [33], Naive Bayes, Random Forest (RF) [34], Light Gradient Boosting Machine (LGBM) [35], Extreme Gradient Boosting (XGBoost) [35], and Decision Tree [36]. These models generate a predicted score between 0 and 1 for each child, which is then classified as ZD or non-ZD based on a defined threshold. Following the initial model comparison, hyperparametric tuning was conducted to further optimize the performance of the best performing algorithm using a RandomizedSearchCV with cross-validation. The search involved 100 iterations with each hyperparameter combination evaluated using 5-fold cross-validation. Finally, the performance of each model was tested before and after balancing the dataset to choose the best predictive model. The model comparison was carried out using the balanced dataset.



Model Evaluation

We evaluated model performance using both train-test split and cross-validation techniques, emphasizing both discrimination and calibration metrics to compare our classification of ZD status against the true ZD status of each child. Discrimination metrics included accuracy, precision, recall (sensitivity), F_1-score, and area under the curve and area under the receiver operating characteristic curve. Accuracy reflects the proportion of correctly classified instances among all tested cases [37], while precision indicates the ratio of true-positive predictions to all positive predictions [38]. Recall measures the proportion of actual positive cases that the model successfully identifies [39], and the F_1-score provides a balanced assessment of model performance, particularly useful in scenarios with class imbalances. In our application, as the objective is to assess the ability of a model to distinguish between positive and negative classes, area under the curve and area under the receiver operating characteristic curve emerged as the most critical measure, as it evaluates the model's ability to effectively distinguish between positive and negative classes by analyzing the trade-off between sensitivity and specificity [40].

In addition to discrimination metrics, we performed calibration to examine how well the predicted probabilities align with actual outcomes. While a model can demonstrate good discrimination, it may still exhibit biases in its risk predictions [41]. Calibration is essential to ensure that predicted probabilities accurately reflect the likelihood of outcomes. To visualize this alignment, we used calibration curves, which plot predicted probabilities against observed results (Figure 4). An ideally calibrated model would form a 45-degree diagonal line, signifying that predicted probabilities correspond closely to actual outcomes [42].

XSL•FO
RenderX

Figure 4. Calibration plot.

Important Feature Selection

Our second objective is to identify the most important predictors of ZD children. To achieve this, we used the best-performing ML model to determine the key features associated with identifying ZD cases. We used a unified framework developed by Lundberg and Lee [43], known as SHAP (SHapley Additive Explanations). This approach is based on Shapley values from cooperative game theory, which assign a value to each feature based on its contribution to the prediction, taking into account all possible combinations of features [44]. A waterfall plot is then created to visualize the cumulative effect of individual features on specific predictions, illustrating how each feature influences the final output. In addition, a beeswarm plot summarizes the distribution of SHAP values across multiple instances, revealing the variability and significance of feature contributions.

Rule Generation

We used rule mining techniques to uncover patterns and relationships within our dataset. We used association rule mining to identify correlations between features through Apriori algorithms [45]. In addition, we applied classification rule mining to generate rules that predict class labels, aiding in the identification of key predictors for ZD children, and explored sequential rule mining to capture temporal patterns where relevant. Following the mining process, we generated actionable insights by formulating human-readable rules that outline conditions (antecedents) and outcomes (consequents) [46]. We assessed the quality of these rules using metrics such as confidence and lift to ensure their reliability and relevance [47].

Ethical Considerations

The research was implemented in compliance with national and international ethical principles. The University of Gondar has provided ethical approval (CMHSSH-UOG IRERC/3/7/2024) to conduct this analysis. For this analyses we used the existing data with primary consent. We used deidentified data (summary data without individuals' identity) to ensure confidentiality. We followed the international standard of strengthening the reporting of cross-sectional studies in epidemiology.

Results

Children's and Mothers' or Caregivers' Characteristics

A total of 13,666 samples of children aged from 12 to 35 months were included for analysis. Nearly 57% (7727/13,666) of the children were younger than 24 - 35 months. The majority (10,204/13,666, 74.7%) of the children were from mothers or caregivers who live in rural areas. Half (6986/13,666, 51.1%) of the children were born from mothers who had not had formal education. More than half (6757/12,419, 54.4%) of the children were from mothers who had no PNC follow-up for the index children. The details are shown in Table 2.

ZD Prevalence

The overall prevalence of ZD in Ethiopia was 18% (95% CI 17.4% - 18.7%). There were regional variations in the prevalence of ZD children. The higher prevalence was observed in Somali (38.8%), Afar (34.2%), and followed by Oromia (22.7%), and the lowest observed in Addis Ababa (0.8%) and Dire Dawa (5 %) (Figure 5).

Performance of the Prediction Models

Seven ML algorithms were used to predict ZD status in Ethiopia, with the LGBM yielding the best performance for both unbalanced and balanced datasets (Table 3). It achieved accuracies of 89% and 93% for the unbalanced and balanced datasets, respectively. Most models showed improved accuracy when applied to the balanced dataset, except for Logistic Regression and Naive Bayes. After balancing the data, both XGBoost and LGBM reached an accuracy of 93%. Notably, the LGBM classifier excelled in terms of area under the curve (AUC) (98%) and sensitivity (92%).

[c]DT: Decision Tree.

Overall, while all ML models performed well on both datasets, those trained on balanced data especially XGBoost and LGBM proved to be more effective in identifying ZD children due to their higher recall and AUC. A comprehensive comparison of the ML algorithms used for ZD children is detailed in Table 3.

After the hyperparameter optimization conducted, the LGBM model achieved robust performance, with an accuracy of 92.4, an AUC of 97.4%, a precision of 93.2%, and a recall of 90.9%. The details are shown in Table 4.

Table . Model performance after hyperparameter tuning for predicting zero-dose children in Ethiopia, 2023.

Model	Accuracy (%)	AUC[a] (%)	Precision (%)	Recall (%)	F_1-score (%)

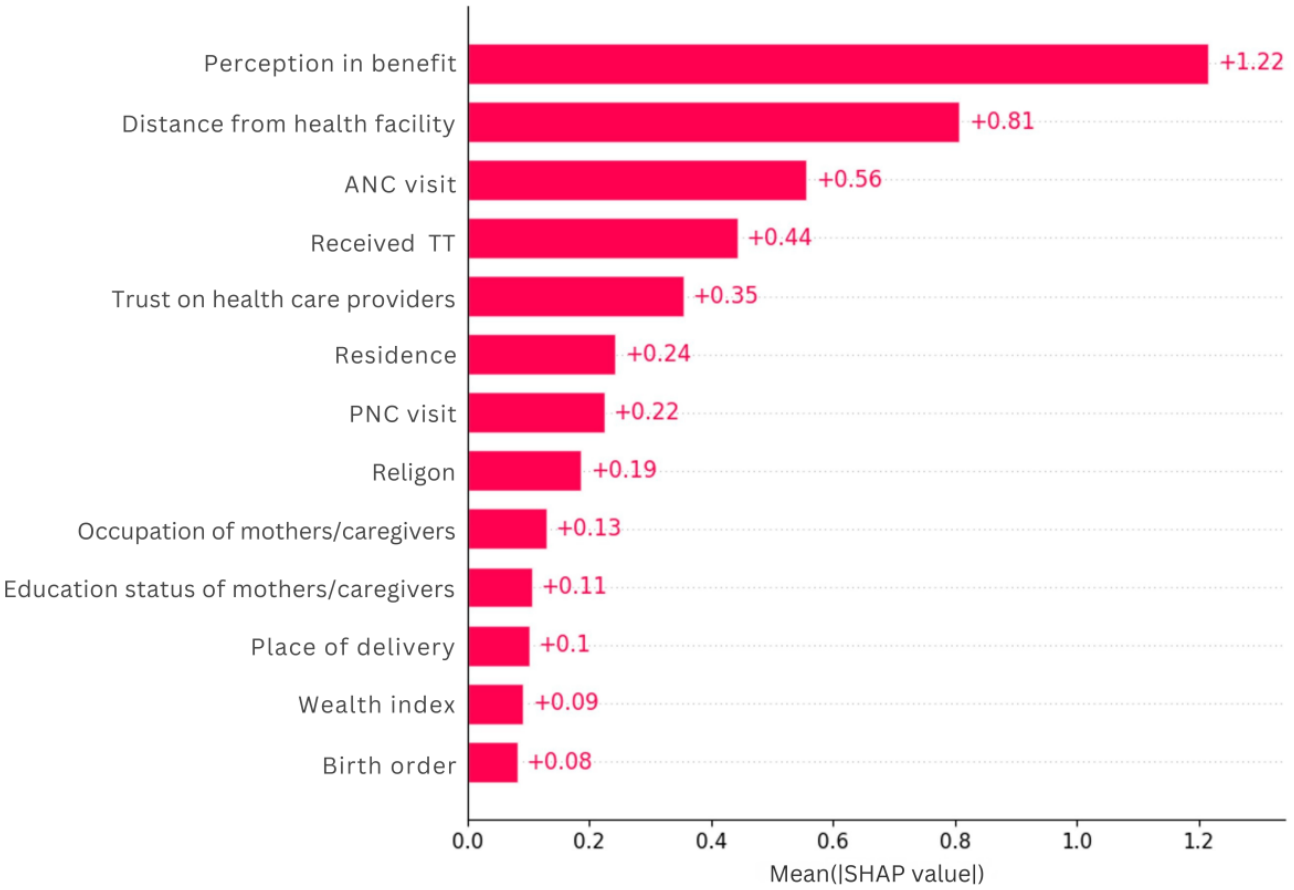
After parameter tuning, the models were further evaluated using 10-fold cross-validation, where XGBoost and LGBM demonstrated comparable accuracies of 93% (Figure 6).

Figure 6. Accuracy of models in 10-fold cross-validation after balancing the dataset for predicting zero-dose children in Ethiopia, 2023. LGBM: Light Gradient Boosting Machine.

Predicting ZD



After building the model by using the training dataset, the performance of the LGBM model was evaluated by the testing dataset. From 2181 ZD children, the model predicted 1991 children correctly (true positive), and out of 2300 non-ZD children, the model predicted 2175 children correctly (true negative). However, the model incorrectly classified 190 ZD samples as non-ZD (false positive) and 125 non-ZD samples as ZD (false negative). The Matthews correlation coefficient was r=0.85 and Cohen κ=0.85. Overall, the model predicted with an accuracy of 93%, recall of 91%, F_1-score of 92%, and 94% precision on test data.

Feature Importance

The Shapley Additive analysis identified that mother's or caregiver's perception of benefit of immunization (+1.13), with whether the distance to immunization site (+0.88), whether the mother received ANC (+0.55), whether the mother received TT (+0.42), and whether trust in health providers (0.41) were the most important features followed by place of residence (+0.35), and PNC visit (+0.25). Wealth index, birth order, and place of delivery were the features with low importance (Figure 7).

XSL•FO
RenderX

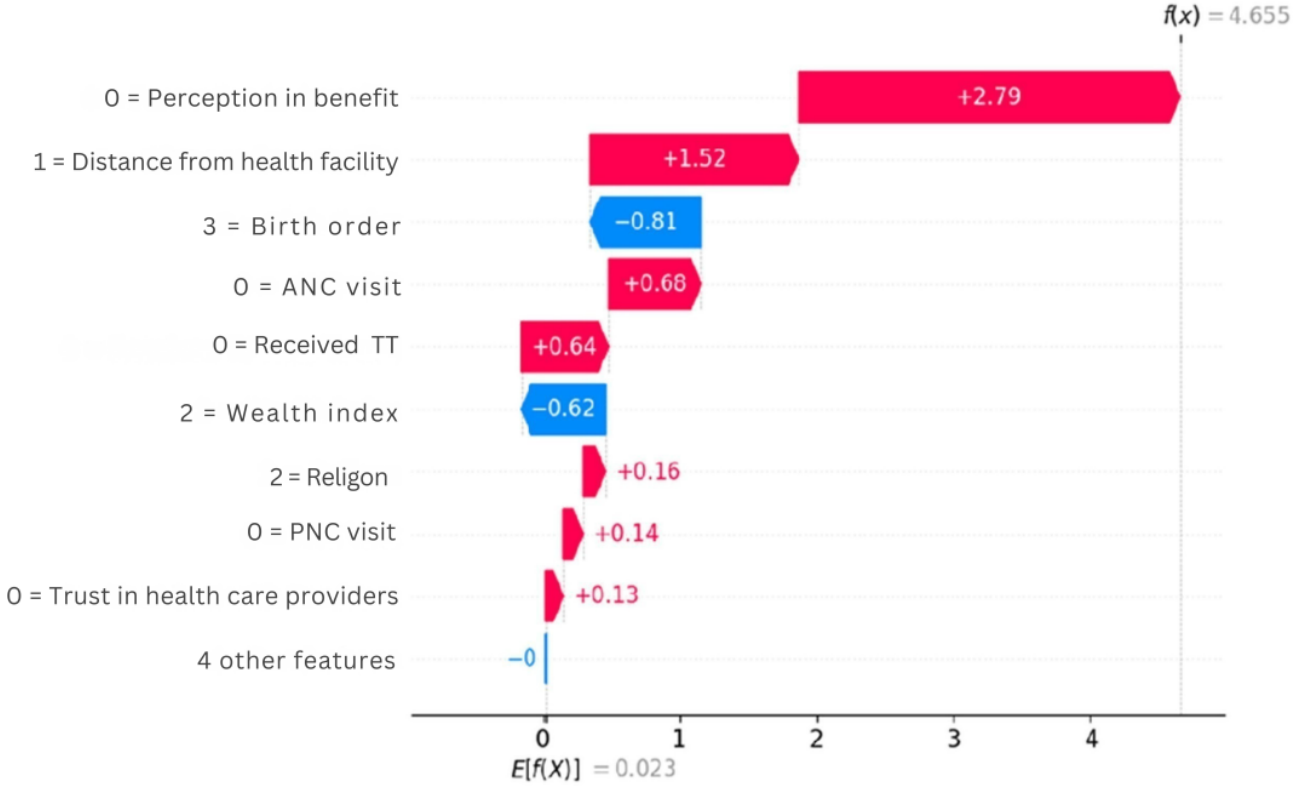


Figure 7. Important features for predicting zero-dose children in Ethiopia, 2023. ANC: antenatal care; PNC: postnatal care; SHAP: SHapley Additive Explanations.

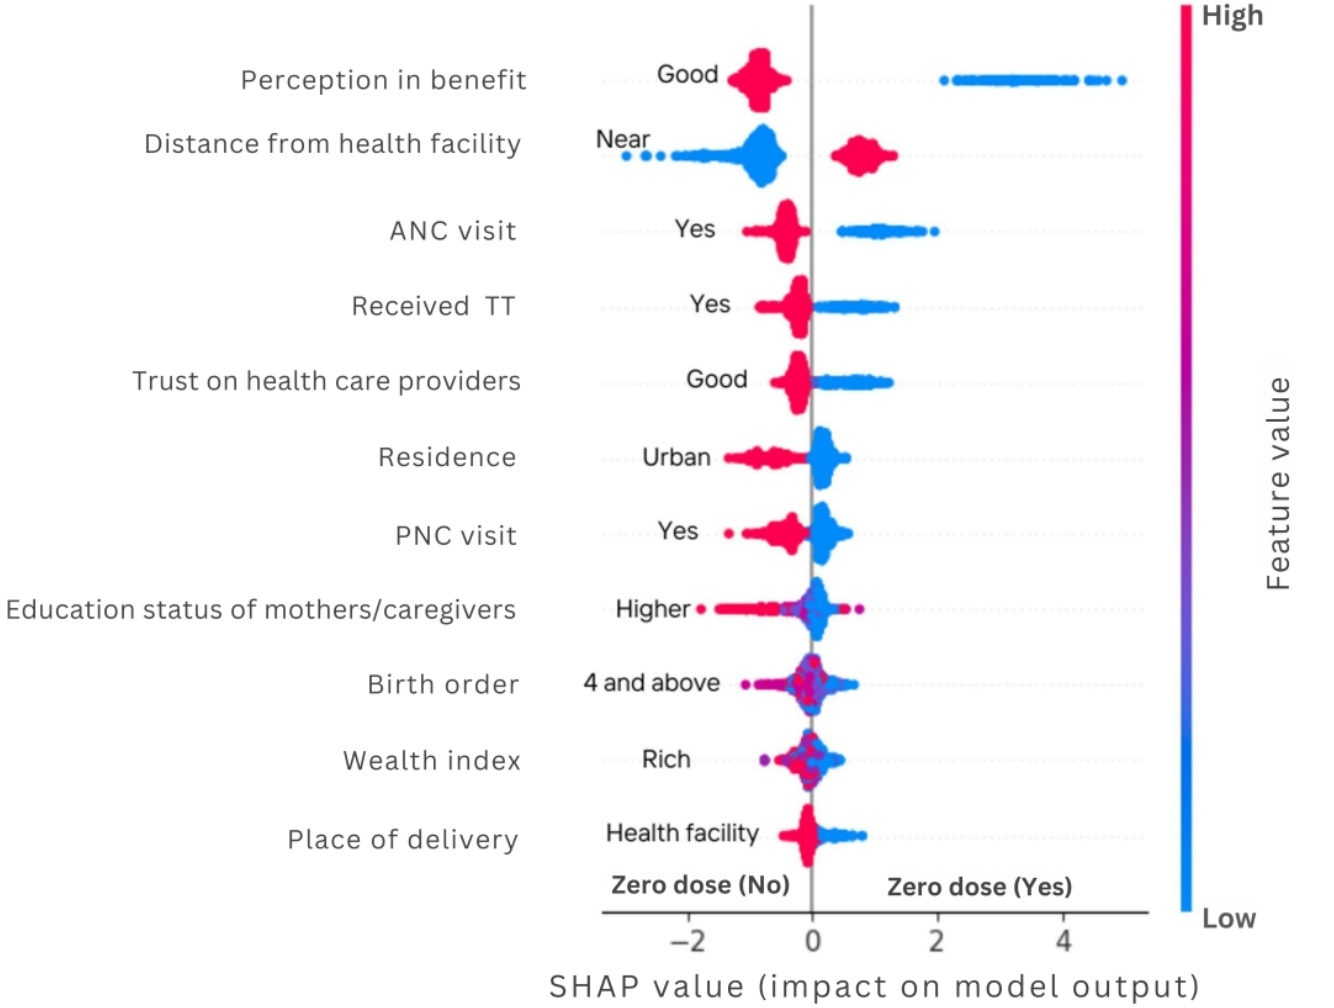
The waterfall chart demonstrates how various factors influence the prediction of ZD vaccination status, starting from a baseline expected value of ($E[f(X)]$=0.023) and culminating in a final prediction of $f(x)$=4.655) indicating that the child is ZD. This indicated that poor perceptions of vaccination benefits, long distances to immunization sites, lack of antenatal and postnatal care visits, absence of TT vaccination, and low trust in health care providers are positively correlated with ZD. Conversely, being in a medium wealth index and having a third birth order is negatively correlated with ZD (Figure 8).

XSL•FO
RenderX

Figure 8. Waterfall plot of first observation value to predict zero-dose children in Ethiopia, 2023. ANC: antenatal care; PNC: postnatal care.



.

As shown in Figure 9, the beeswarm plot illustrates the impact of various predictor variables on ZD status, with distinct colors representing risk levels: red dots indicate high-risk values, while blue dots denote low-risk values for the predictor variables. The feature of perception exhibits a wide range of SHAP values, highlighting its significant influence on the model's predictions. A poor perception of the benefits of vaccination notably increases the likelihood of a child being classified as ZD. In addition, distance from health care facilities is strongly associated with ZD status, where far distances correlate with a higher likelihood of being unvaccinated. Other contributing factors include a lack of ANC visits, PNC visits, TT vaccination, low wealth index, low trust in health care providers, and home delivery, all of which contribute to the prediction of the positive class (ZD).

Rule Generation

The rule generation process was done based on important attributes selected by the best performing ML model LGBM. Moving beyond individual feature importance, we used association rule mining to identify complex, multifactorial profiles of ZD children and to rigorously validate the interactions suggested by the SHAP analysis. This generated a set of human-interpretable "if then" rules, each validated by key metrics: support (prevalence of the rule in the data), confidence (conditional probability of the outcome), and lift (strength of the association above random chance). The rule generation process was done based on important attributes selected by the best performing ML model LGBM. The strongest rule (rule 1: lift = 2.17, confidence = 0.90) indicates that children whose caregivers live far from a health facility and have a poor perception of vaccination benefits have a 90% probability of being ZD, a risk 2.17 times higher than random. Rule 2 (confidence = 0.81) shows that combining distance with a lack of ANC and poor trust in providers creates another high-risk pathway, while rule 5 (confidence = 0.79) highlights the potent combination of no tetanus vaccination, no ANC, and distance. Crucially, these rules reveal critical synergies, while SHAP identified "distance" and "ANC" as top individual predictors, rule mining quantified how their combination with other factors (eg, rule 8: no ANC + Far distance, confidence = 0.72) creates a risk profile with a distinctly high probability of the outcome. This provides programmatically actionable insights, demonstrating that interventions must target these intersecting barriers simultaneously rather than in isolation to effectively reach ZD children. A total of 9 association rules were generated, and the details of the rules are shown in Textbox 1.

Discussion

Principal Findings

Using the data from the most recent National Immunization Evaluation Survey in Ethiopia, we applied different supervised machine algorithms to assess how well the models predict whether a child is likely to be ZD and to identify the important predictor variables. We trained and compared 7 ML classifiers on both unbalanced and balanced datasets, using a train-test split, hyperparameter tuning, and 10-fold cross-validation for robust evaluation. A variety of socioeconomic, demographic, and health-related factors were included to enhance the model's predictions and facilitate important feature selection.

Our findings demonstrate that these ML algorithms are effective in identifying children at high risk of being ZD. Among the 7 models tested, LGBM emerged as the top performer, achieving an AUC of 97.4%, recall of 90.9%, accuracy of 92.4%, precision of 93.2%, and an F_1-score of 92.1%. These evaluation metrics underscore the model's strong capability in predicting ZD children. The high AUC indicates the model's effectiveness in distinguishing between children who receive immunization services and those who do not. Notably, a recall of 90.9% signifies that the model successfully identifies 90.9% of ZD children, who are often at greater risk for missing vaccines and vaccine-preventable diseases.

In addition to LGBM, both XGBoost and RF algorithms performed well, each achieving an accuracy of 92.2% and 91.6%, respectively. These results are consistent with previous studies that recognized XGBoost [48] and RF [49] as top performers in similar contexts. While these metrics indicate robust performance for critical health issues such as immunization, it is crucial to validate the model in real-world settings. Such testing will enhance its utility as a tool for guiding public health initiatives aimed at increasing vaccination rates and improving access to essential health care services for unvaccinated children.

Using an ML model, health care workers can pinpoint specific households and communities with ZD children, allowing them to shift from broad campaigns to targeted household visits. By leveraging the model's insights on local perceptions and socioeconomic barriers, they can tailor their communication and services, such as setting up mobile clinics, to overcome specific challenges and efficiently use scarce resources, ensuring that vaccines reach those most in need.

The second objective of the study was to identify important attributes that could predict ZD among children aged 12 - 35 months. Using SHAP analysis, the study found that perception of immunization benefit, ANC utilization, distance from vaccination site, maternal TT vaccination status, and trust in health providers were the most important features to identify at-risk children for ZD.

The top predictor was poor maternal perception with a SHAP value of 1.13 (Figure 7). This indicates that a negative perception of mothers or caregivers increases the likelihood of a child being ZD, likely because parental beliefs directly influence health care decisions regarding vaccination. This finding aligns with previous studies showing that parental beliefs and attitudes significantly affect a child's vaccination status [50,51].

ANC utilization was another important feature, with a SHAP value of 0.55, indicating that a lack of ANC is strongly linked to a child being ZD. This finding is in line with the previous

XSL•FO
RenderX

similar studies done [48,52,53]. This could be due to the fact that ANC visits enable mothers to access integrated health services, be more likely to receive information on immunization schedules, build trust in the health system, and improve adherence to health services [54-56].

In addition, the study found several important predictors. Maternal TT vaccination was a key factor; mothers who received the TT vaccine were more likely to have their children vaccinated, a finding consistent with studies from Sudan and Bangladesh [57,58]. Postnatal care visit was another important predictor. This service is likely gaining a better understanding of vaccination importance and feeding practices, thus reducing missed vaccinations [59,60]. In addition, maternal education was an important predictor, with uneducated mothers having a higher risk of ZD children than those with at least a primary education, firming up the known link between maternal literacy and vaccination rates and primary education. This finding is in line with previous research linking maternal literacy to vaccination completeness [61-65]. The other finding of this study is rule mining and generation. Using association rule mining with the Apriori algorithm, the study uncovered strong relationships between various socioeconomic, demographic, and health-related factors and ZD status. Key determinants, including distance from health facility, perception of vaccination benefits, trust in health care providers, ANC, place of delivery, place of residency, and TT vaccines were the most important features predicting ZD. Confidence levels for these findings ranged from 71% to 90%, indicating robust associations.

Findings from association rule 1 indicated that the probability of a child being ZD would be 90%, if and only if the mothers or caregivers were far from the health facility and had poor perception on immunization. This may be because mothers or caregivers who are far from the facility may not have access to health education directly or indirectly, affecting health-seeking behavior and health service utilization such as vaccination. The second rule also included poor trust in health care providers and lack of ANC visits as predictors for ZD. A child ZD would be 80% if mothers or caregivers have trust in providers and had no ANC follow-up for the index child.

Strengths and Limitations

This study had several strengths worth mentioning. We used national-level survey data from 463 EAs ensuring generalizability across the country and providing a current snapshot of the ZD situation. A key strength is that our analysis uses various ML algorithms from the field of data science, which significantly aids in identifying and targeting ZD children more effectively. These advanced analytical techniques allow us to process large datasets and uncover insights that may not be immediately apparent through traditional methods. At the same time, this study identified the risk factors of ZD that may help policy makers and planners to design tailored interventions to identify and reach the unvaccinated children.

This study was subject to some limitations. First, although we used national-level data, we did not include data from the Tigray region, which is one of the administrative regions of the country, due to security issues. Second, the study did not include health system side predictors such as availability of vaccination supplies and vaccines. Finally, we could not do external validation for the modes due to the lack of real-world data.

Conclusions

The developed ML models effectively predict children at risk of being ZD and identify associated risk factors. Among these models, the LGBM model demonstrated the best performance in predicting ZD children. Key features linked to ZD status include access to immunization sites, maternal health service utilization (such as antenatal and postnatal care, place of delivery, and TT vaccination), and perceptions regarding immunization.

By implementing ML models, public health interventions can be more precisely targeted at the most vulnerable groups. This approach may address inequities in vaccination coverage by identifying specific sociodemographic, economic, and health-related factors associated with ZD children. Consequently, it aids in the formulation and implementation of effective policies and strategies to improve vaccination rates. Strengthening the continuum of care for mothers, raising awareness among caregivers, and improving immunization access through outreach strategies may help in reducing the high burden of ZD children.

Acknowledgments

The authors would like to thank the University of Gondar for the unwavering support. In addition, the authors extend their sincere thanks to the Ministry of Health of Ethiopia for granting them access to the data that were critical for their study.

Funding

No external financial support or grants were received from any public, commercial, or not-for-profit entities for the research, authorship, or publication of this article.

Data Availability

The datasets generated or analyzed during this study are available from the corresponding author on reasonable request.

Abstract

Background: Tuberculosis (TB) remains one of the leading infectious causes of morbidity and mortality worldwide, with children representing a particularly vulnerable group. In the Democratic Republic of the Congo, pediatric TB continues to be underdiagnosed and underreported, particularly in rural health zones such as Kabondo Dianda.

Objective: This study aimed to assess the knowledge, perceptions, and practices of guardians and health care providers regarding pediatric TB in Kabondo Dianda health zone by using the knowledge, attitude, and practice framework.

Methods: A descriptive cross-sectional study was conducted in 5 diagnostic and treatment centers between January 2020 and December 2022. Guardians of children diagnosed with TB (163/163, 100%) were recruited exhaustively through facility registers and community health workers, while health care providers (27/27, 100%) were included through convenience sampling. Data were collected using a structured questionnaire adapted from national and World Health Organization guidelines. The instrument was pretested with 15 guardians and 5 health care providers in a neighboring health zone to ensure clarity, cultural appropriateness, and reliability; internal consistency was confirmed with Cronbach α (α=0.82). Composite scores were calculated for knowledge, perceptions, and practices. Descriptive statistics and chi-square and Fisher exact tests were applied, with significance set at $P<.05$.

Results: Guardians demonstrated partial biomedical knowledge: cough was widely recognized as a symptom (123/163, 75.5%); however, misconceptions persisted, with 29% (47/163) attributing TB to supernatural causes and 52% (85/163) believing domestic animals were vectors. Preventive knowledge was limited, with only 26.4% (43/163) mentioning the Bacille Calmette-Guérin vaccination. Care seeking was often delayed, with 38.7% (63/163) consulting only after treatment failure and 25.8% (42/163) after symptom worsening. Health care providers showed higher knowledge scores but limited diagnostic engagement: only 18.5% (5/27) reported routine use of GeneXpert, and 3.7% (6/163) of pediatric cases received HIV screening. Misconceptions were significantly associated with lower knowledge scores among guardians ($P=.03$).

Conclusions: Pediatric TB underreporting in Kabondo Dianda reflects both systemic and behavioral determinants. Applying the knowledge, attitude, and practice framework highlights how cultural beliefs, limited preventive knowledge, and weak diagnostic engagement interact to hinder early detection and management. Strengthening community education, training health care providers on latent TB and HIV coinfection, and improving diagnostic infrastructure are essential to reduce morbidity and mortality among children in rural Democratic Republic of the Congo.

Introduction

Background

Tuberculosis (TB) remains one of the leading infectious causes of morbidity and mortality worldwide. According to the World Health Organization (WHO) Global Tuberculosis Report 2024, an estimated 10.6 million people developed TB in 2023, including 1.2 million children aged <15 years [1]. Children represent a particularly vulnerable group; however, pediatric TB continues to be underdiagnosed and underreported due to its paucibacillary nature and the limited sensitivity of available diagnostic tools [2].

In sub-Saharan Africa, weak health systems, limited health care provider capacity, and low community awareness exacerbate the burden of pediatric TB [3]. In the Democratic Republic of the Congo, TB incidence remains high, with over 220 cases per 100,000 inhabitants in 2023, placing the country among the 30 high-burden nations identified by WHO [1]. Despite national control efforts, pediatric TB has not received adequate attention. In Haut-Lomami province, particularly the Kabondo Dianda health zone, notification rates for pediatric TB remain persistently low (9%-15% between 2016 and 2022) [4]. This underreporting reflects both systemic barriers (limited diagnostic infrastructure and weak referral systems) and behavioral barriers (delayed care seeking and misconceptions about transmission).

Community-level misconceptions are widespread: nearly half of caregivers believe TB is not transmissible, while more than one-quarter attribute the disease to supernatural causes [4]. Knowledge of latent TB is virtually absent among both caregivers and health care providers. Although some health care providers demonstrate high knowledge scores, most remain unaware of latent TB forms, limiting their ability to implement preventive strategies [4]. Care-seeking behavior is also delayed, with many caregivers seeking care only after treatment failure or disease progression. At the facility level, diagnostic capacity is limited: HIV screening is rarely performed, and GeneXpert testing is underused [4].

To guide this study, we adopted the knowledge, attitude, and practice (KAP) framework, which posits that gaps in knowledge and distorted perceptions influence health-seeking practices and ultimately affect disease outcomes [5]. Applying this framework allows us to analyze how caregiver beliefs and health care provider practices interact to shape pediatric TB detection and management in rural Democratic Republic of the Congo.

Knowledge Gap

While pediatric TB is recognized as a neglected issue globally, few studies have systematically assessed the interplay of caregiver perceptions, health care provider practices, and systemic barriers in rural Congolese settings. Existing literature highlights underreporting but does not adequately explain the behavioral and cultural determinants underlying delayed diagnosis and poor management [6,7].

Objectives

This study aims to assess the knowledge, perceptions, and practices of guardians of children and health care providers regarding pediatric TB in Kabondo Dianda health zone using the KAP framework. Specifically, we seek to identify misconceptions and cultural beliefs influencing care seeking, evaluate health care provider diagnostic and preventive practices, and highlight systemic gaps that hinder early detection. By addressing these dimensions, the study contributes to evidence-based strategies for strengthening pediatric TB control and reducing morbidity and mortality among children in resource-limited environments.

Methods

Study Design and Setting

This study used a descriptive cross-sectional design, which is appropriate for generating baseline evidence on knowledge, perceptions, and practices without testing causal hypotheses. The research was conducted in the Kabondo Dianda health zone, Haut-Lomami province, Democratic Republic of the Congo. The zone comprises 19 health areas, of which 5 were designated as diagnostic and treatment centers (CSDTs) by the Provincial TB Coordination Unit. These sites were selected for their strategic location, patient volume, and relevance to pediatric TB surveillance. Data collection took place between November 25 and 30, 2022, covering pediatric TB cases diagnosed from January 2020 to December 2022. As the study period extended over 3 years, recall bias was anticipated and is explicitly acknowledged as a limitation of descriptive studies.

Recruitment and Study Population

Participants were recruited from the 5 CSDTs officially designated by the Provincial TB Coordination Unit in the Kabondo Dianda health zone. Recruitment of guardians was exhaustive: all caregivers of children aged <15 years who had been diagnosed with pulmonary TB between January 2020 and December 2022 were identified through facility registers and community health workers. Of the 166 eligible guardians, 163 were successfully enrolled, while 3 were excluded due to permanent displacement following local flooding. This approach ensured near-complete coverage of the target population and minimized selection bias.

Health care providers were recruited using convenience sampling. All personnel directly involved in TB diagnosis and management at the selected facilities were invited to participate, including medical directors, nurses, laboratory technicians, and TB focal points. A total of 27 health care providers were

XSL•FO
RenderX

enrolled, representing the full spectrum of staff engaged in pediatric TB services. Although exploratory in nature, this sample reflects the operational realities of TB care in the health zone.

Eligibility criteria for guardians required being the primary caregiver of a child aged <15 years diagnosed with pulmonary TB in one of the selected CSDTs during the study period. Health care providers were eligible if they were actively assigned to the selected facilities at the time of data collection and directly responsible for TB-related services. Exclusion criteria included permanent relocation outside the health zone or refusal to provide informed consent. By combining exhaustive recruitment of guardians with comprehensive inclusion of available health care providers, the study population was designed to capture both community-level experiences and facility-based practices relevant to pediatric TB detection and management.

Data Collection

Data were collected using a structured questionnaire administered via KoboCollect, adapted from national TB guidelines and WHO recommendations. The tool was pretested on 15 guardians and 5 health care providers in a neighboring health zone to ensure clarity, cultural appropriateness, and reliability. Internal consistency was assessed using Cronbach α, which yielded a coefficient of 0.82. The questionnaire contained closed-ended questions covering sociodemographic characteristics, knowledge of TB transmission and prevention, perceptions of severity and stigma, and care-seeking practices. Health care provider–specific items assessed diagnostic capacity, GeneXpert use, HIV screening, and referral procedures.

Instrument Validation

Prior to data collection, the questionnaire was subjected to a pretest to ensure clarity, cultural appropriateness, and reliability. The tool was administered to a sample of 15 guardians and 5 health care providers in a neighboring health zone. Feedback from this pilot exercise was used to refine wording and improve comprehension. Internal consistency was assessed using Cronbach α, which yielded a coefficient of 0.82, indicating good reliability. This validation process confirmed that the instrument was suitable for use in the study population and aligned with WHO recommendations for KAP surveys [1].

Variables and Operational Definitions

Independent variables included type of facility, health care provider profile (qualification and years of experience), guardian characteristics (age, education, occupation, and household size), availability of diagnostic tools, and accessibility of services. Dependent variables included knowledge level, perceptions, practices such as timely versus delayed care seeking, and health care provider performance in screening, referral, and counseling. High knowledge was defined as at least 75% correct responses, based on WHO KAP survey guidelines. Delayed care seeking was defined as seeking care only after symptom worsening or treatment failure. Diagnostic engagement referred to the use of GeneXpert or HIV testing for pediatric TB cases.

Handling of Missing Data

Given the descriptive nature of the study, missing data were managed using a complete-case analysis approach. Partially missing responses were excluded from composite score calculations. Sensitivity analyses confirmed that exclusion did not alter key descriptive findings.

Data Analysis

Data were analyzed using SPSS (version 25.0; IBM Corp). Descriptive statistics such as frequencies, proportions, medians, and IQRs were calculated to summarize participant characteristics and responses. Exploratory associations were examined using $\chi^2$and Fisher exact tests, with statistical significance set at $P<.05$. Composite scores were developed to assess knowledge and perception levels, consistent with descriptive study standards.

Ethical Considerations

Ethics approval for this study was obtained from the ethics committee of the School of Public Health, University of Kinshasa (approval number ESP/CE/205/2024). Written authorization was also granted by the head of the health division of Haut-Lomami Province and the chief medical officer of the Kabondo Dianda health zone. Investigators consistently carried these authorizations during fieldwork and presented them whenever requested by local authorities or participants. Written informed consent was obtained from all participants prior to their inclusion in the study.

Results

Overview

The sociodemographic characteristics of guardians and health care providers are shown in Table 1. Of the 163 guardians, 82 (50.3%) were female, with a median age was 37 (IQR 30-43) years. Farming was the predominant occupation (n=88, 54%), and nearly half lived in households with 5 to 9 members (n=80, 49.1%). Of the 27 health care providers, 22 (81.5%) were male, with a median age of 35 (IQR 10) years. All were officially employed, but only 8 (29.6%) had completed secondary school and 1 (3.7%) had attained university-level education.

Table 1. Sociodemographic characteristics of the guardians and health care providers.

Characteristic	Guardians (n=163)	Health care providers (n=27)
Female sex, n (%)	82 (50.3)	5 (18.5)
Age (years), median (IQR)	37 (13)	35 (10)
Farming occupation, n (%)	88 (54)	0 (0)
Household size: 5-9, n (%)	80 (49.1)	12 (44.4)

XSL•FO
RenderX

Knowledge of TB Transmission

Knowledge of TB transmission is shown Table 2. Coughing was correctly identified as a transmission route by 75.5% (123/163) guardians and 88.9% (24/27) health care providers. Health care providers demonstrated broader awareness, with 20 (74.1%) citing sneezing, 18 (66.7%) mentioning speaking, and 16 (59.3%) recognizing laughing. Guardians showed limited awareness beyond coughing, with only 36 (22.1%) mentioning sneezing and 12 (7.4%) mentioning laughing. Differences between guardians and health care providers were statistically significant for sneezing (P=.001) and laughing (P<.001).

Table 2. Knowledge of tuberculosis transmission.

Transmission mode	Guardians (n=163), n (%)	Health care providers (n=27), n (%)	*P* value
Coughing	123 (75.5)	24 (88.9)	.12
Sneezing	36 (22.1)	20 (74.1)	.001
Speaking	55 (33.7)	18 (66.7)	.01
Laughing	12 (7.4)	16 (59.3)	<.001

Knowledge of TB Prevention

Knowledge of TB prevention is shown in Table 3. Preventive knowledge was markedly higher among health care providers. All 100% (27/27) identified good nutrition, 26 (96.3%) cited Bacille Calmette-Guérin (BCG) vaccination, and 19 (70.4%) mentioned respiratory hygiene. Guardians reported lower knowledge, with 26.4% (43/163) citing good nutrition, 43 (26.4%) mentioning BCG vaccination, and 18 (11%) citing covering the mouth or avoiding overcrowding. Differences between groups were statistically significant for BCG vaccination and respiratory hygiene (P<.001).

Table 3. Knowledge of tuberculosis prevention.

Prevention method	Guardians (n=163), n (%)	Health care providers (n=27), n (%)	*P* value
Good nutrition	43 (26.4)	27 (100)	<.001
BCG[a] vaccination	43 (26.4)	26 (96.3)	<.001
Covering mouth	18 (11)	19 (70.4)	<.001

[a]BCG: Bacille Calmette-Guérin.

Perceptions of TB Transmission

Among health care providers, 89% (24/27) correctly perceived TB as communicable and transmitted by coughing. In contrast, only 55% (90/163) guardians recognized TB as communicable. Misconceptions persisted: 47 (29%) guardians attributed TB to supernatural causes, and 85 (52%) believed domestic animals were vectors. Even among health care providers, 3 (11%) cited evil spirits, and 25 (93%) implicated animals.

Care-Seeking Practices

Formal health facilities were the first point of care for 49.1% (80/163) guardians and 70.4% (19/27) health care providers. Guardians frequently sought care at pharmacies (n=43, 26.4%) or traditional healers (n=32, 19.6%). Timing of care seeking showed delays: 63 (38.7%) guardians consulted only after treatment failure, and 42 (25.8%) after symptom worsening. Among health care providers, 9 (33.3%) reported initiating care after deterioration. Reasons for choosing facilities included free effective treatment (n=60, 36.8% guardians and n=19, 70.4% health care providers) and accessibility (n=39, 23.9% guardians).

Diagnostic Practices

Despite the availability of diagnostic tools, use was limited. Only 3.7% (6/163) pediatric cases received HIV screening, and 18.5% (5/27) health care providers reported routine use of GeneXpert. These findings confirm systemic gaps in diagnostic engagement.

Discussion

Principal Findings

This descriptive study revealed substantial gaps in knowledge, perceptions, and practices regarding pediatric TB among guardians and health care providers in the Kabondo Dianda health zone. Guardians demonstrated limited awareness of transmission routes beyond coughing, and misconceptions such as attributing TB to supernatural causes or domestic animals were common. Health care providers showed broader biomedical knowledge but still reported beliefs inconsistent with scientific evidence. Preventive knowledge was markedly higher among health care providers, particularly regarding nutrition and BCG vaccination, whereas guardians cited these measures less frequently. Care-seeking practices were delayed, with many guardians consulting health services only after treatment failure or symptom worsening. Diagnostic engagement remained low, with limited use of GeneXpert and HIV screening.

Comparison With Prior Studies

These findings align with previous research in sub-Saharan Africa, which has documented persistent misconceptions about airborne transmission and cultural beliefs attributing TB to nonbiomedical causes [8,9]. Similar studies in rural contexts have shown that delayed care seeking is often driven by poverty, geographic isolation, and reliance on traditional healers [10]. The low use of GeneXpert and HIV screening mirrors national reports from the Democratic Republic of the Congo, where

XSL•FO
RenderX

diagnostic infrastructure exists but is underused due to limited training and supervision [11]. The disparities between guardians and health care providers in knowledge of prevention echo findings from other African settings, where community-level education remains insufficient [12].

Implications for Practice and Policy

The results underscore the urgent need to strengthen pediatric TB control strategies in rural Democratic Republic of the Congo. Community education campaigns should specifically target misconceptions, emphasizing airborne transmission and the importance of early care seeking. Health care provider training must address latent TB, HIV coinfection, and systematic use of GeneXpert. Health system strengthening is required to improve diagnostic infrastructure, referral pathways, and integration of national guidelines into routine practice. Finally, culturally sensitive communication strategies should be developed, respecting local beliefs while promoting evidence-based practices. Collaboration between community health workers, diagnostic centers, and local authorities can enhance case tracking and reduce stigma.

Limitations

This study has several limitations inherent to descriptive cross-sectional designs. Recall bias may have affected guardian responses, given the 3-year study period. Selection bias is possible due to convenience sampling of health care providers, which limits representativeness. Self-reported data may be subject to social desirability bias. Moreover, the study was conducted in 5 diagnostic centers within Kabondo Dianda and may not reflect practices in other health zones. Despite these limitations, exhaustive sampling of guardians and inclusion of all active health care providers strengthen internal validity.

Conclusions

This descriptive study conducted in Kabondo Dianda health zone highlights persistent gaps in knowledge, perceptions, and practices related to pediatric TB among guardians and health care providers. While health care providers demonstrated relatively higher biomedical knowledge, misconceptions remained, and diagnostic engagement was limited. Guardians showed restricted awareness of transmission and prevention, with delayed care-seeking behaviors, contributing to underreporting and late diagnosis.

By applying the KAP framework, the study underscores how cultural beliefs, limited preventive knowledge, and systemic barriers interact to hinder early detection and effective management of pediatric TB in rural Democratic Republic of the Congo. These findings emphasize the need for targeted community education, health care provider training on latent TB and HIV coinfection, and improved diagnostic infrastructure.

Although limited by recall bias, selection bias, and reliance on self-reported data, this study provides valuable baseline evidence for strengthening pediatric TB control strategies in resource-constrained settings. Future research should explore interventions that integrate culturally sensitive communication with systematic diagnostic practices to reduce morbidity and mortality among children.

Acknowledgments

The authors would like to thank the management team of the Kabondo Dianda health zone, the heads of health areas, and the community health workers for their invaluable support during data collection. They also express their gratitude to the mothers and caregivers who generously participated in this study, sharing their time and experiences to advance pediatric tuberculosis research. No generative artificial intelligence tools were used in the writing or analysis of this manuscript. All content was produced by the authors. All authors declared that they had insufficient funding to support open access publication of this manuscript, including from affiliated organizations or institutions, funding agencies, or other organizations. JMIR Publications provided article processing fee support for the publication of this paper.

Data Availability

The anonymized dataset used for this study is available from the corresponding author upon reasonable request.

Funding

This research received no funding from public, commercial, or not-for-profit agencies.

Authors' Contributions

JDY led the conceptualization of the study, with supporting input from FIM. The methodology was primarily developed by FIM, assisted by PKI. Data curation was conducted by PKI, with support from AM. Formal analysis was led by FIM, assisted by AK. The investigation was carried out by PKI, with equal contribution from AM. Project administration was overseen by FIM, with support from JDY. Resources were provided by AK. Supervision was led by JDD, with support from FIM. Validation was performed by JDY and JDD. Visualization was led by AM, assisted by PKI. The original draft was written by JDY, with supporting contributions from FIM. All authors contributed equally to the review and editing of the manuscript.

Abstract

Background: Hemolytic disease of the fetus and newborn (HDFN) is a life-threatening condition resulting from maternal-fetal erythrocyte antigen incompatibility. Although anti–Rhesus D (RhD) prophylaxis has reduced RhD-associated cases, HDFN persists due to non-RhD antibodies and gaps in prevention. Population-based data on maternal and neonatal outcomes and recurrence patterns are limited.

Objective: This study aimed to characterize maternal and neonatal outcomes, health care use patterns, and recurrence rates of HDFN across pregnancies.

Methods: We conducted a retrospective cohort study of 464,711 pregnancies within the Kaiser Permanente Southern California system from January 1, 2008, to June 30, 2022. HDFN diagnoses were confirmed using validated natural language processing–assisted manual chart review and followed through 2023. Maternal characteristics, neonatal outcomes, and health care use were compared by HDFN status, and recurrence patterns were evaluated among individuals with ≥2 pregnancies. Chi-square tests and Wilcoxon rank-sum tests were used to compare characteristics between HDFN and non-HDFN pregnancies. Statistical significance was defined as $P<.05$.

Results: Among all pregnancies, 139 of 464,711 (0.03%) were diagnosed with HDFN. Women with HDFN were more likely than those without HDFN to be older (aged ≥35 years; n=42, 30.2% vs n=97,146, 20.9%) and multiparous (n=121, 87.1% vs n=264,766, 57%). Infants affected by HDFN had higher rates of preterm birth (n=40, 28.4% vs n=42,240, 9.5%), low birth weight (<2500 g; n=22, 15.6% vs n=31,740, 7.1%), and neonatal jaundice (n=92, 65.2% vs n=162,465, 36.4%) than non-HDFN infants. Delivery hospitalizations (median 5.0, IQR 2.0-7.5 days vs median 2.0, IQR 1.0-2.0 days) and neonatal intensive care unit stays (median 4.0, IQR 0.0-7.0 days vs median 0.0, IQR 0.0-0.0 days) were longer, and maternal nondelivery hospitalizations were more frequent (n=27, 19.4% vs n=23,228, 5%) among pregnancies complicated by HDFN. Among women with a prior HDFN-affected pregnancy, 83.3% (n=25) experienced recurrence in a subsequent pregnancy. Of these recurrent cases, 32% (n=8) were severe, and 75% (n=6) involved fetal anemia requiring at least 1 intrauterine transfusion.

Conclusions: HDFN was rare but was associated with substantial maternal and neonatal morbidity, including higher rates of preterm birth, increased neonatal intensive care unit admissions, and greater health care use. Recurrence was frequent and clinically significant, underscoring the importance of early surveillance and proactive management strategies.

KEYWORDS

hemolytic disease of the fetus and newborn; HDFN; alloimmunization; neonatal outcomes; recurrence; health care resource use; perinatal treatment; fetal anemia

Introduction

Hemolytic disease of the fetus and newborn (HDFN) is a life-threatening condition caused by maternal-fetal erythrocyte antigen incompatibility, in which maternal immunoglobulin G alloantibodies cross the placenta and lead to fetal hemolytic anemia [1]. In severe cases, HDFN can result in fetal hydrops, fetal demise, and significant neonatal morbidity. The risk is particularly high for early-onset severe HDFN (≤24 weeks of gestation), which carries an elevated likelihood of stillbirth and adverse neonatal outcomes [2-4].

Widespread implementation of routine anti–Rhesus D (RhD) prophylaxis has substantially reduced RhD alloimmunization [5]. However, HDFN persists because of alloimmunization from non-RhD antigens or gaps in prophylaxis, highlighting ongoing challenges in prevention [5-7]. Current management for high-risk pregnancies includes middle cerebral artery (MCA) Doppler monitoring and intrauterine transfusions (IUTs) to prevent fetal hydrops and anemia-related pregnancy loss [8]. Although IUTs have improved perinatal survival [8], they remain invasive and carry procedure-related risks, including fetal demise, preterm birth, and other complications [2,3].

Alternative approaches, such as intravenous immunoglobulin (IVIG) and plasmapheresis, have been used to delay or reduce the need for IUTs, but outcomes remain suboptimal, and many affected pregnancies still require multiple procedures [8]. Beyond the immediate treatment challenges, recurrence of HDFN in subsequent pregnancies remains a major concern. Prior reports suggest that recurrence is common and may present with earlier onset or greater severity, yet robust epidemiological data remain limited [9].

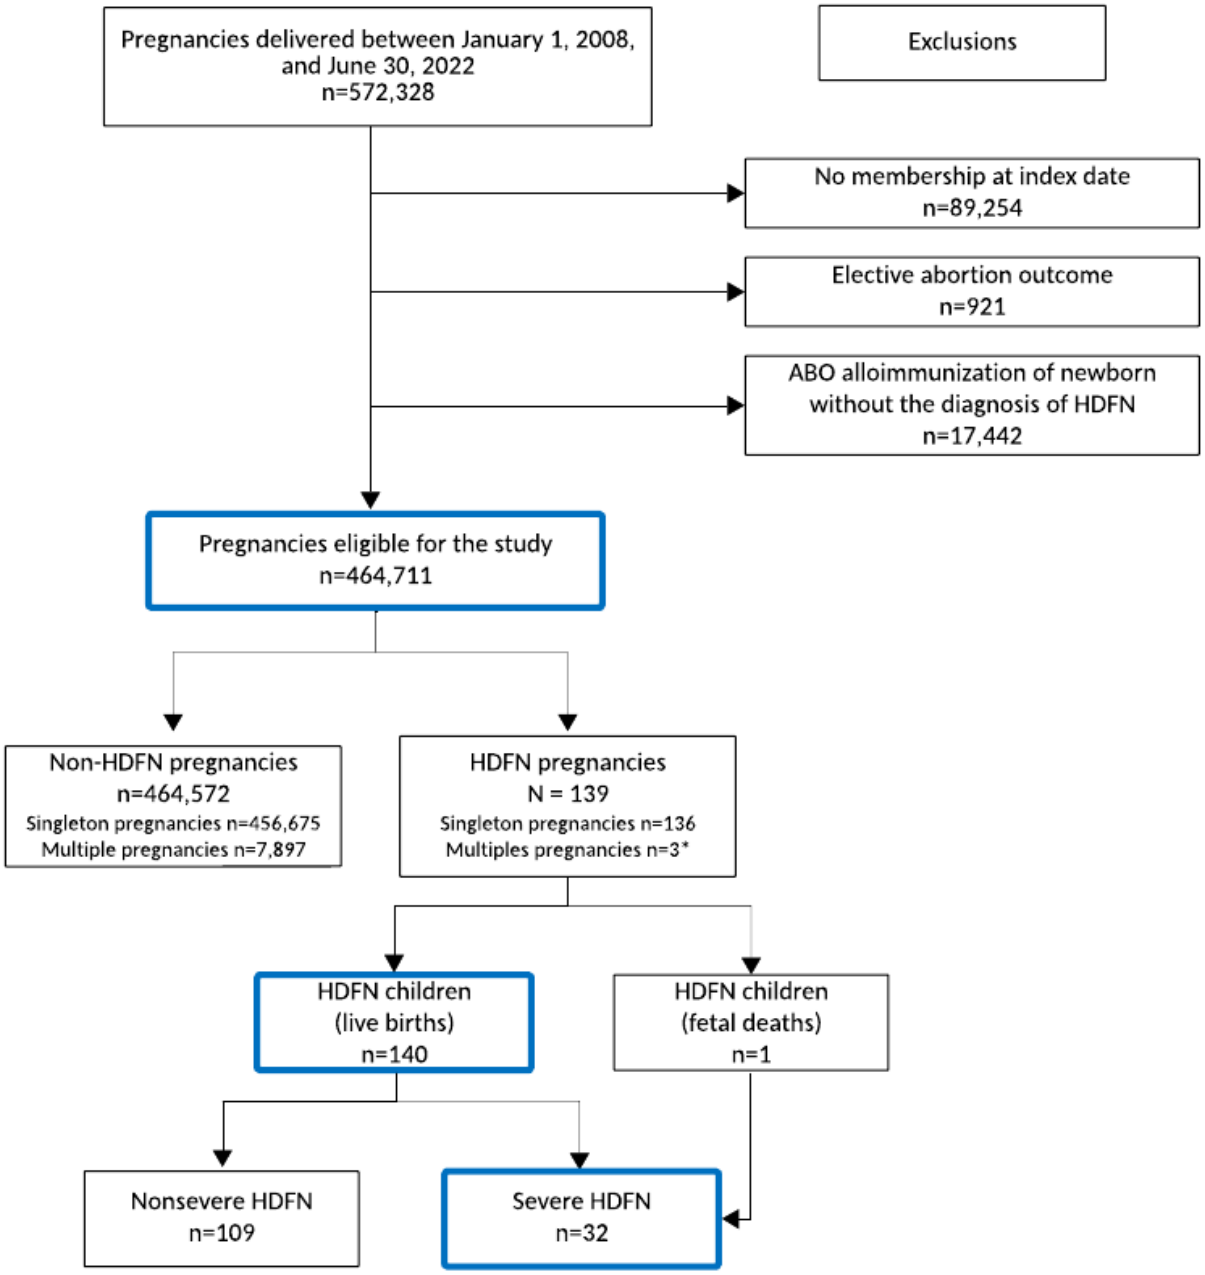
A prior study suggested that maternal characteristics, along with medical and obstetric factors, may be associated with the diagnosis of HDFN [10]. Despite advancements in fetal monitoring and intervention, population-based evidence remains limited regarding whether HDFN impacts neonatal and maternal health care resource use. Furthermore, recurrence patterns in subsequent HDFN-affected pregnancies have not been well characterized within large integrated health systems. Therefore, this study aimed to (1) describe maternal and neonatal characteristics and health care use associated with HDFN and (2) evaluate recurrence patterns in subsequent pregnancies.

Methods

Ethical Considerations

All study activities were reviewed and approved by the Kaiser Permanente Southern California (KPSC) Institutional Review Board with exemption of informed consent (IRB#13503). The study involved a secondary analysis of existing electronic health record (EHR) data and posed no more than minimal risk to participants.

Study Design



We conducted a retrospective cohort study using EHRs from KPSC, a large integrated health care system serving >4.7 million members across 15 hospitals and 235 medical offices. The KPSC population is racially, ethnically, and socioeconomically diverse and is representative of the Southern California population [11-13]. The KPSC database contains detailed sociodemographic, outpatient, inpatient, medical, and obstetric records, as well as pharmacy and laboratory records.

Study Population

Among 572,328 pregnancies delivered between January 1, 2008, and June 30, 2022, we excluded pregnancies that did not have KPSC membership at the start of pregnancy (n=89,254, 15.6%), those that ended in elective abortion (n=921, 0.2%), and cases with ABO alloimmunization without a confirmed HDFN diagnosis (n=17,442, 3%). The final analytic cohort included 464,711 (81.2%) pregnancies (Figure 1).

XSL•FO
RenderX

Figure 1. Study cohort composition. *Included 3 twin pregnancies, of which 5 infants had hemolytic disease of the fetus and newborn (HDFN), and 1 infant did not have HDFN.

HDFN Status and Classification

HDFN cases (from 2008 to 2022) were identified using a validated algorithm incorporating the *International Classification of Diseases, Ninth and Tenth Revisions, Clinical Modification* diagnostic and procedural codes, laboratory records, and clinical free-text extraction from KPSC EHRs and were followed through 2023. Trained abstractors conducted comprehensive chart reviews to confirm HDFN status, severity, and recurrence, with uncertain cases adjudicated by our maternal-fetal medicine specialist (MJF). Details of our HDFN identification process, including the natural language processing (NLP)–assisted chart review process, have been published previously [14].

Using structured EHR data (codes, medications, and laboratory results) and NLP-processed notes, candidate HDFN pregnancies were identified using likely indicators of maternal antibodies or titers; maternal or infant HDFN diagnosis, transfusion, or hydrops; infant IVIG; jaundice or phototherapy; and first Rho(D) immune globulin. We adjudicated selected indicator combinations by chart review and excluded cases of ABO alloimmunization alone. Of 464,711 eligible pregnancies, 136 (0.03%) were confirmed as HDFN. Indicator prevalence ranged from 0.02% (n=72; infant IVIG) to 34.53% (n=160,456; jaundice

XSL•FO
RenderX

or phototherapy) overall and from 32.35% (n=44; infant IVIG) to 100% (n=136; maternal antibody positivity) among cases. Several combinations of 4 to 6 indicators had 100% positive predictive value; 80.88% (n=110) of cases had maternal antibody positivity, maternal or infant HDFN diagnosis, and infant jaundice or phototherapy.

HDFN in Subsequent Pregnancies

We identified subsequent pregnancies among women with ≥2 pregnancies in the KPSC health care system between January 1, 2008, and December 31, 2023. Then, we ordered all pregnancies chronologically using the pregnancy episode start date, with the earliest pregnancy during the study period designated as the index pregnancy. All later pregnancies for the same individual were classified as subsequent pregnancies. For each subsequent pregnancy, HDFN status was determined using the same NLP-assisted manual chart review algorithm applied to index pregnancies.

Maternal and Neonatal Characteristics

Maternal characteristics included age, race or ethnicity (non-Hispanic White, non-Hispanic Black, Hispanic, non-Hispanic Asian or Pacific Islander, other or multiple, or unknown), median household income (US <$30,000, US $30,000-$49,999, US $50,000-$69,999, US $70,000-$89,999, US ≥$90,000, or missing) based on US Census Bureau data, and insurance type (Medicaid, commercial, private, or other). Smoking, alcohol, and substance use during pregnancy were assessed, along with reproductive history (parity, gravidity, and prepregnancy BMI [kg/m^2]). Clinical conditions included gestational weight gain (in pounds) and maternal comorbidities, such as asthma, chronic hypertension, pregestational diabetes, renal disease, and autoimmune disorders. We also evaluated obstetric complications, including preterm premature rupture of membranes, small-for-gestational-age or intrauterine growth restriction, and fetal hydrops.

Neonatal characteristics included infant sex, birth weight (grams), gestational age at birth (weeks), and head circumference (centimeters). Perinatal outcomes assessed were preterm birth, fetal death, and Apgar scores <7 at 5 minutes. Neonatal complications evaluated included birth asphyxia, hypoxic-ischemic encephalopathy, jaundice, kernicterus, and cerebral palsy.

Health Care Resource Use

Health care resource use was evaluated separately for pregnant women and neonates. For pregnant women, we examined hospital length of stay, intensive care unit admission, and the timing of prenatal care initiation. Health care encounters, including hospitalizations, emergency department visits, urgent care visits, and outpatient visits, were assessed from pregnancy through 6 weeks post partum. For neonates, we examined the length of delivery hospitalization, neonatal intensive care unit (NICU) admission and length of stay, and health care resource use from delivery through 1 year, including hospitalizations, emergency department visits, urgent care visits, and outpatient visits.

Treatment Modalities

We evaluated both individual and combined treatment modalities among pregnant women, including IUTs, MCA Doppler ultrasounds, RhoGAM, antenatal steroids, magnesium sulfate, group B *Streptococcus* prophylaxis, and plasmapheresis. For neonates, treatment modalities included red blood cell transfusions, exchange transfusions, phototherapy for hyperbilirubinemia, and IVIG.

Statistical Analysis

We analyzed maternal and neonatal characteristics, health care resource use, and treatment patterns according to HDFN diagnosis status. Recurrence of HDFN was examined by estimating the frequency and proportion of pregnancies with a subsequent HDFN-affected pregnancy, including classification by severity and onset. Among recurrent HDFN cases, we described the distribution of gestational age at first IUT and summarized associated clinical features, such as fetal anemia and the number of IUTs performed. We excluded pregestational diabetes, birth asphyxia, hypoxic-ischemic encephalopathy, and cerebral palsy from all analyses due to the small sample size.

For categorical variables, frequencies and percentages were estimated, and comparisons were made using chi-square tests or Fisher exact tests when cell sizes were small. For continuous variables, means and SDs were calculated and compared using Wilcoxon rank-sum tests to account for potentially nonnormally distributed characteristics. Statistical significance was defined as a 2-sided P value <0.05. All analyses were conducted using SAS (version 9.4; SAS Institute Inc).

Results

Pregnancy Cohort

Among 464,711 singleton and multiple pregnancies in KPSC members between January 1, 2008, and June 30, 2022, 139 (3 per 10,000) were identified as HDFN pregnancies. There were 3 twin pregnancies, for which all but 1 fetus was diagnosed with HDFN, resulting in 140 HDFN live births and 1 HDFN fetal death (Figure 1).

Maternal Characteristics

Women with HDFN pregnancies were older (aged ≥35 years; n=42, 30.2% vs n=97,146, 20.9%; P<.007) and had varied racial or ethnic distributions, with a higher proportion of non-Hispanic White women (n=55, 39.6% vs n=125,971, 27.1%) and a lower proportion of Hispanic women (n=57, 41% vs n=213,468, 45.9%; P=.005; Table 1**)**. Medicaid coverage was more common among HDFN cases (n=22, 15.8% vs n=44,561, 9.6%; P=.03), as was renal disease (n=8, 5.8% vs n=8331, 1.8%; P<.001). HDFN cases were also more likely to be multiparous (n=121, 87.1% vs n=264,766, 57%) and multigravida (n=128, 92.1% vs n=326,828, 70.4%; P<.001). Other sociodemographic, behavioral, and clinical characteristics were similar between groups.

Neonatal Characteristics and Outcomes

Infants affected by HDFN had lower birth weight and gestational age distributions, with higher proportions born weighing <2500 g (n=22, 15.6% vs n=31,740, 7.1%; *P*<.001) and at 35 to 36 weeks' gestation (n=24, 17% vs n=25,296, 5.7%) or 33 to 34 weeks' gestation (n=12, 8.5% vs n=8753, 2%; *P*<.001; Table 2). Preterm birth was more common among HDFN cases (n=40, 28.4% vs n=42,240, 9.5%; *P*<.001). Head circumference was slightly smaller (mean 33.5, SD 2.26 cm vs mean 34.0, SD 2.72 cm; *P*=.04). Neonatal jaundice occurred more frequently in HDFN cases (n=92, 65.2% vs n=162,465, 36.4%; *P*<.001). Sex distribution and fetal death rates were similar between groups.

Health Care Resource Use in Pregnancy

Women with HDFN pregnancies had longer hospital stays (median 3.0, IQR 2.0-4.0 days vs median 2.0, IQR 1.0-3.0 days; *P*<.001) and initiated prenatal care later, with more patients beginning care in the second trimester (n=21, 15.1% vs n=23,175, 5%) or third trimester (n=5, 3.6% vs n=2477, 0.8%; *P*<.001; Table 3). Nondelivery hospitalizations were more common among HDFN cases (n=27, 19.4% vs n=23,228, 5%; *P*<.001). Urgent care visits were less frequent (n=23, 16.6% vs n=116,021, 25%; *P*=.02), while emergency department visits were similar between groups.

Table 3. Health care use among pregnant women based on hemolytic disease of the fetus and newborn (HDFN) diagnosis status.

Neonatal Health Care Resource Use

Children with HDFN had longer delivery hospitalizations (median 5.0, IQR 2.0-7.5 days vs median 2.0, IQR 1.0-2.0 days; *P*<.001) and longer NICU stays (median 4.0, IQR 0.0-7.0 days vs median 0.0, IQR 0.0-0.0 days; *P*<.001) than those without HDFN (Table 4). NICU admission within 4 weeks of birth was more frequent among HDFN cases (n=85, 60.7% vs n=45,739, 10.3%; *P*<.001). Emergency department, urgent care, and outpatient visit frequencies were similar between groups.

Table 4. Health care use among children based on hemolytic disease of the fetus and newborn (HDFN) diagnosis status.

Health care use	Total live births (n=444,315)	Pregnancies with HDFN (n=140)	Pregnancies without HDFN (n=444,175)	*P* value
Length of delivery hospitalizations (days)				<.001[a]
Mean (SD)	2.9 (7.9)	7.4 (11.6)	2.9 (7.9)	
Median (IQR)	2.0 (1.0-2.0)	5.0 (2.0-7.5)	2.0 (1.0-2.0)	
Length of NICU[b] stay during the delivery hospitalization (days)				<.001[a]

Treatment Modalities

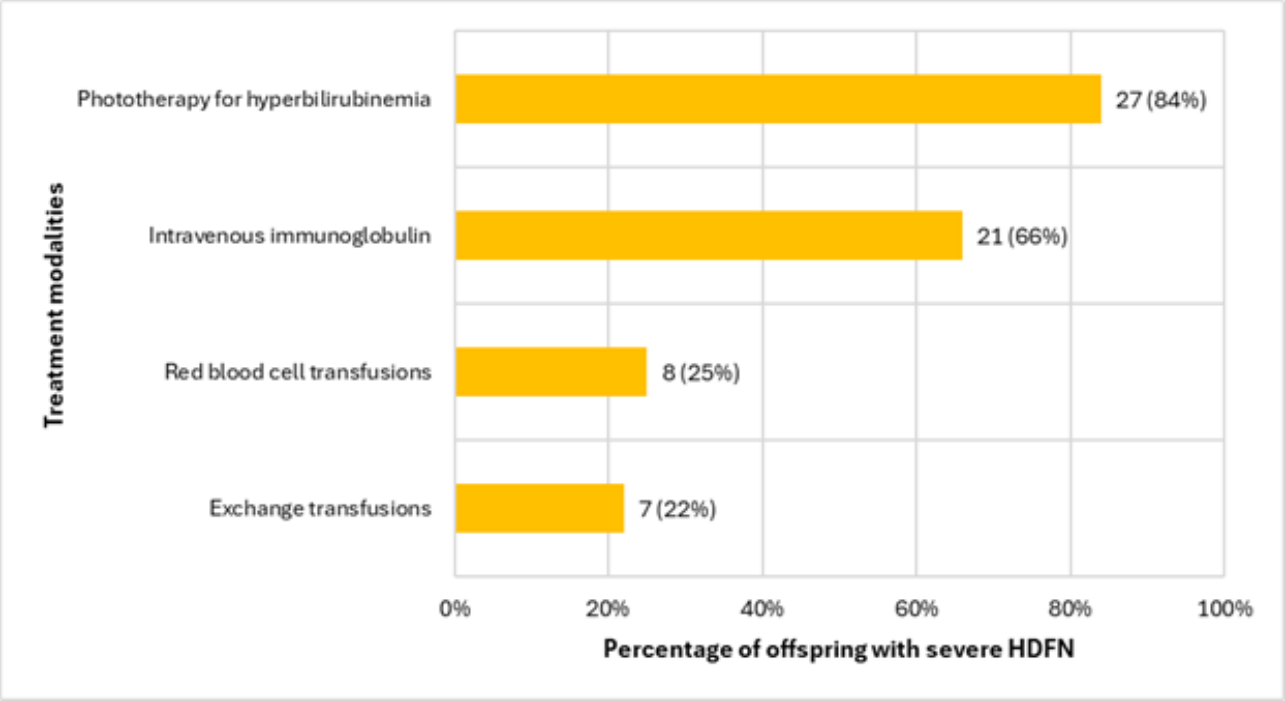

Figure 2 shows the frequency and percentage of treatment modalities for severe HDFN pregnancies (n=32, 100%). MCA Doppler ultrasound was the most frequently used modality among severe HDFN pregnancies (n=27, 84%), followed by IUT (n=17, 53%) and antenatal steroids (n=13, 41%). Group B *Streptococcus* prophylaxis was used in a smaller proportion of cases (n=6, 19%), while magnesium sulfate was rarely used (n=1, 3%). Plasmapheresis and RhoGAM were not used in this severe HDFN cohort.

Figure 2. Distribution of treatment modalities among pregnancies with severe hemolytic disease of the fetus and newborn (HDFN; N=32). MCA: middle cerebral artery.

Among offspring with severe HDFN, phototherapy for hyperbilirubinemia was the most common treatment (n=27, 84%), followed by IVIG (n=21, 66%). Red blood cell transfusions (n=8, 25%) and exchange transfusions (n=7, 22%) were used less frequently (Figure 3).

Figure 3. Distribution of treatment modalities among offspring with severe hemolytic disease of the fetus and newborn (HDFN).

XSL•FO
RenderX

Subsequent Pregnancies

Overall, 0.05% (53/101,623) subsequent pregnancies were affected by HDFN, with the majority occurring among those with a prior HDFN-affected pregnancy. The recurrence of HDFN in a subsequent pregnancy was substantially more common among pregnancies with a prior history of HDFN than among those without prior HDFN (12/16, 75% vs 41/101,607, 0.04%; *P*<.001).

Limiting the analysis to women with a prior HDFN-affected pregnancy who conceived again, recurrence was common: 83.3% (25/30) experienced HDFN in the next pregnancy, while 16.7% (5/30) did not (Table 5). Most recurrent cases were classified as nonsevere (n=17, 68%), although approximately one-third were severe (n=8, 32%). Among severe recurrences, onset occurred more often after 24 weeks of gestation (n=5, 62.5%). Evidence of fetal anemia was observed in 75% (n=6) of severe cases, necessitating at least 1 IUT.

Table 5. Hemolytic disease of the fetus and newborn (HDFN) status, severity, and management in subsequent pregnancies among women with a prior HDFN diagnosis.

Characteristics	Subsequent pregnancies, n (%)
HDFN status of the subsequent pregnancy (n=30)	
Non-HDFN pregnancy	5 (16.7)
HDFN pregnancy	25 (83.3)
HDFN severity among recurrent cases (n=25)	
Nonsevere HDFN	17 (68)
Severe HDFN	8 (32)
Onset among severe cases (n=8)	
Early onset (≤24 weeks of gestation)	3 (37.5)
Late onset (>24 weeks of gestation)	5 (62.5)
Documented fetal anemia[a]	6 (75)
≥1 intrauterine transfusion	6 (75)

[a]Fetal anemia was defined as a fetal hemoglobin level <0.84 multiples of the median. Fetal hemoglobin (g/100 ml) was calculated by dividing hematocrit (%) by 3.

Discussion

Principal Findings

In this large retrospective cohort study, we characterized maternal and neonatal outcomes, health care use, and recurrence patterns associated with HDFN. Although HDFN was rare, affected pregnancies demonstrated notable differences in clinical presentation and health care use, and recurrence in subsequent pregnancies was frequent.

Maternal Characteristics, Neonatal Outcomes, and Health Care Use

HDFN pregnancies differed from unaffected pregnancies across several maternal and neonatal characteristics. Mothers with HDFN were older and more frequently multiparous, consistent with alloimmunization developing over multiple pregnancies. Neonates affected by HDFN had higher rates of preterm birth and low birth weight and were substantially more likely to require NICU care, with longer delivery and NICU hospital stays. These findings reflect the substantial burden of hemolysis-related anemia and hyperbilirubinemia, which often necessitate specialized postnatal care.

Health care use was elevated in pregnancies affected by HDFN. Women experienced more nondelivery hospitalizations and initiated prenatal care later, suggesting potential gaps in early detection and management. Neonates required significantly greater inpatient resources, amplifying the strain on NICU services. Together, these patterns underscore the complex care needs associated with HDFN and highlight the substantial burden on both obstetric and neonatal services.

HDFN Recurrence in Subsequent Pregnancies

A key contribution of this study is the rates of HDFN recurrence. Among individuals with ≥2 pregnancies, 83.3% had HDFN in a subsequent pregnancy, and approximately one-third of recurrent cases were severe. Reported HDFN recurrence rates vary by cohort definition and outcome threshold. With recurrence defined as any HDFN in any subsequent pregnancy among women with a prior HDFN (EHR indicator or NLP phenotype) diagnosis, our rate is higher than the 56% treatment-requiring proportion reported among subsequent pregnancies of RhD-immunized women in Sweden [15], consistent with our higher-risk entry criterion and broader outcome. In severe cohorts, recurrence can be even higher: among women with a prior history of IUT and a subsequent antigen-positive fetus, 86% required repeat IUT [9]. Most recurrent cases demonstrated clinical features consistent with significant fetal anemia, including high frequencies of documented anemia and the need for IUTs. Recurrent cases that required IUTs often underwent treatment at earlier gestational ages than initially affected pregnancies, reflecting accelerated alloimmune fetal anemia in later pregnancies. These findings support current clinical observations that alloimmunization can lead to earlier and more clinically significant fetal disease in subsequent pregnancies. However, the presence of both severe

XSL•FO
RenderX

and nonsevere recurrences suggests heterogeneity in disease expression.

Clinical Implications

Our findings have important implications for antenatal counseling and management. Given both the high recurrence pattern and the potential for early or severe disease in subsequent pregnancies, enhanced surveillance strategies may be warranted. Early referral to maternal-fetal medicine, closer monitoring of antibody titers, and earlier MCA Doppler assessment may help identify high-risk pregnancies before significant fetal anemia develops. The observed variability in recurrence severity also supports individualized monitoring plans rather than uniformly escalating surveillance.

Furthermore, EHR-based algorithms could be developed to flag women at risk for HDFN recurrence at prenatal care intake, enabling early review of prior history, timely laboratory testing, and consideration of early intervention to optimize outcomes. Moreover, population-based studies are needed to clarify long-term neonatal outcomes and quantify the health care costs associated with HDFN across the perinatal period. Further research should also evaluate whether early maternal biomarkers or alloantibody trends can better predict severity or recurrence to guide the timing of surveillance and intervention. Studies of antenatal treatment strategies may help determine approaches that delay or reduce the need for IUTs. Finally, prospective multicenter investigations could validate these findings and explore long-term neurodevelopmental outcomes in affected neonates, addressing critical gaps in the current evidence.

Strengths and Limitations

A major strength of this study is the large, demographically diverse, population-based cohort with comprehensive EHR data, enabling robust identification of HDFN cases and recurrence patterns. The manual chart review and adjudication process further strengthened data accuracy. However, our study is not without limitations. As this was a descriptive study, our findings should be interpreted accordingly. The retrospective design of this study may limit data capture in the EHR; therefore, misclassification of HDFN status, its severity, onset timing, and clinical features, such as fetal or neonatal anemia, is possible, particularly when documentation in health records was incomplete. Furthermore, future studies with larger samples and more events are needed to support multivariable regression modeling and adjustment for potential confounders. Although we used NLP-assisted manual chart review with adjudication to improve case ascertainment, cases from pregnancies managed in contracting hospitals (outside KPSC) may have been missed. This study was conducted within a single integrated health care system, which, while racially and socioeconomically diverse, may limit generalizability to nonintegrated health care settings.

Conclusions

HDFN remains a clinically significant condition associated with substantial perinatal morbidity and elevated health care use. Recurrence in subsequent pregnancies was common, and many recurrent cases exhibited severe fetal anemia requiring early IUT. These findings underscore the importance of timely identification, targeted surveillance strategies, and continued research aimed at improving antenatal management and reducing the burden of disease.

Abstract

Background: Chronic preventable diseases represent a major burden in Canada, often rooted in unhealthy behaviors established during childhood. Despite recommendations for routine screening, most children are not assessed due to clinical barriers. This paper presents the early development of Project DISCO, a self-administered, digital preappointment tool to screen for and support healthy lifestyle behaviors, including physical activity, sleep, nutrition, and screen time, in children aged 2 to 12 years.

Objective: This study aimed to explore clinicians' and parents' needs and past experiences with health technology; integrate their insights into the development of a digital tool for promoting health behaviors; and evaluate the usability, relevance, and acceptability of this tool.

Methods: Three semistructured focus group and interview sessions were conducted with primary care clinicians and parents. Participants were recruited at the Groupe de Médecine de Famille Universitaire Saint-Hubert using purposive and convenience sampling: clinicians were recruited internally, whereas parents of children aged 2 to 12 years were invited via emails sent by clinic staff. Data were analyzed using a combination of inductive and deductive approaches. Findings informed iterative refinements throughout the codevelopment of the digital tool for promoting healthy lifestyle behaviors in children.

Results: A total of 8 participants took part in 6 discussions, including 5 parents of children aged 3 to 12 years and 3 primary care clinicians. Hybrid thematic analysis identified six themes: (1) the potential of a digital tool to promote healthy habits in pediatrics; (2) implementation challenges and opportunities, including integration of the tool into clinical workflow; (3) adherence to and engagement with the tool, with suggestions for reminders and involvement of nurses; (4) perceived limitations and improvement of the screening tool, particularly the nutrition and sleep questionnaires; (5) feedback on the screening report and intervention emphasizing clarity and actionable guidance; and (6) perceived clinical value and opportunity costs. Insights from these discussions guided refinements of the digital tool.

Conclusions: The findings support the tool's relevance and inform its ongoing development. A feasibility study is planned prior to a randomized controlled trial.

Introduction

In Canada, chronic preventable diseases cause 65% of all deaths [1], affect 44% of Canadians, and account for 58% of the annual health care budget [2]. Unhealthy lifestyle behaviors such as physical inactivity, excessive screen time, unhealthy diet, and poor sleep hygiene are key contributors to chronic preventable conditions, including obesity, diabetes, cardiovascular disease, several types of cancer, and psychological illnesses [3-9]. These behaviors often originate in childhood and tend to track into adulthood [9-11] and cluster [5,12-14].

Despite recommendations for systematic screening by several organizations, including the Canadian Task Force on Preventive Health Care [15-17], most children are not screened for lifestyle behaviors. Barriers include limited clinician time, competing priorities, fear of upsetting families, and low perceived self-efficacy of clinicians [18-22].

Digital preappointment screening can help overcome these barriers [23-26]. Compared to traditional methods, it is more time efficient, scalable, and generally well accepted by clinicians and families [23,24,26-32]. In pediatrics, digital screening, brief intervention, and referral to treatment (SBIRT) has helped address adolescent substance abuse [31,33-35] by identifying risky behaviors, initiating behavior change, and connecting patients to support resources [36,37]. Similar tools have been developed for parents to support childhood obesity in primary care [38].

Active stakeholder involvement is essential in developing screening and intervention tools [39-41]. Parents can help ensure the tool's relevance and fit within real-life family contexts [42], whereas clinicians inform its feasibility and acceptability in practice [31,43,44]. For example, an intervention to support young adults with type 1 diabetes was codeveloped with patients, researchers, and health care professionals, helping identify priorities and concrete strategies to improve care [45].

This study sought to develop, alongside stakeholders, a tool to target health behaviors in children. Specifically, the primary objective of this study was to refine a screening and intervention tool using end user feedback obtained through focus groups [46]. This paper describes the codevelopment and refinement through structured focus groups with parents and clinicians of a self-administered digital preappointment screening and intervention tool targeting physical activity, sleep, nutrition, and screen time in children aged 2 to 12 years in general pediatric primary care.

Methods

Preliminary Data and Tool Development

This study is part of a larger research program that was initiated between October 2021 and November 2022, with a needs assessment conducted with 114 families at the Groupe de Médecine de Famille Universitaire Saint-Hubert, a suburban family medicine group [47]. This needs assessment confirmed clinicians' interest in obtaining more information about children's lifestyle behaviors, highlighted the prevalence of unhealthy behaviors in this population, and revealed parents' interest in the development of a preappointment screening tool for lifestyle behaviors. The current manuscript describes the subsequent step of tool refinement through focus groups with parents and clinicians.

A first iteration of our SBIRT tool used three inputs: (1) literature on behavioral science frameworks, including nudges and comparisons that improve real-world decision-making [48,49] and health behavior change [49,50] supported by evidence on physical activity [51,52] and nutrition [53-55] in adults and promising pediatrics data [56]; (2) input from clinicians and family partners [25,35,57-59]; and (3) existing tools such as the RIPPLE (Resource Information Program for Parents on Lifestyle and Education) program, an eHealth SBIRT tool developed by Ball and van Mierlo [25,38,58,60] to prevent pediatric obesity.

More specifically, behavioral sciences were used to inform both the structure and the content of the tool given the promise of this domain to strengthen pediatric nutrition interventions. Insights into cognitive biases and parental motivation—which can be sought through the health behavior screening process by inquiring about motivation to change and beliefs about their children's behaviors relative to group averages—can enable the development of more targeted and effective strategies that support the long-term adoption of healthy eating behaviors in children [49]. Although primarily focused on dietary habits, these strategies are broadly applicable to health behavior change. In this study, we sought to leverage these behavioral science insights through promising approaches such as personalized risk communication [61], the "fresh start effect" [62,63], implementation intentions [64,65], fostering internalization of healthy behaviors [66,67], and strengthening self-regulation [68-70]. The use of these frameworks seeks to enable enhanced parental engagement and facilitate the integration of behavior change into daily family life, notably by establishing a concrete and specific link between a health behavior and the action required to improve it, which may support the repetition of healthier behaviors and eventual automatization [49].

SBIRT Content and Description

Following the standard approach in the literature [25,38,60], our tool consists of 3 main sections: screening questionnaire, brief intervention, and referral to resources (Table 1).

XSL•FO
RenderX

Table 1. Screening, brief intervention, and referral to treatment tool core components.

Components	Description
Screening	• Parents complete a digital, self-administered questionnaire covering the family's demographic information and the child's health behaviors (physical activity, sleep, nutrition and screen time). The questions were informed by the results of a prior needs assessment.
Brief intervention	• After screening, families receive a personalized report summarizing all behaviors and highlighting those not meeting national health guidelines. • Feedback, codeveloped with Evolution Health (van Mierlo, CEO) and family partners, includes behavioral strategies (eg Specific, Measurable, Achievable, Relevant, Timebound (SMART) goals and nudges). • Age-appropriate educational materials are emailed, and results are shared with clinicians to support counseling.
Referral to resources	• For each behavior not meeting the guidelines, parents receive a curated list of community resources tailored to their child's age and needs. • These resources, selected with input from health care professionals and parent partners, are shared with parents based on the behaviors they indicate interest in changing on the brief, personalize report page.

Tool Refinement: Focus Groups

The focus group discussions served the primary objective of the study: the development and refinement of our screening and intervention tool using end user feedback [46]. Specifically, the focus groups were intended to (1) gain insights into the needs of clinicians and parents regarding a digital tool aimed at promoting healthy behaviors; (2) explore participants' past experiences with health technology; (3) integrate insights obtained from the first focus group into the tool development process; and (4) assess the perceived usability, relevance, acceptability, and accuracy of the developed tool. In the first and second focus groups, participants engaged with static mock-ups of the interface, which included the intended questions for each health behavior, and discussed and refined the visual outputs. This led to the fully operational screening and personalized intervention tool evaluated in the third focus group. During this focus group, participants interacted with the working interface, including the full screening questionnaire; immediate personalized feedback reports; comparative normative data displays; color-coded results across physical activity, sleep, nutrition, and screen time domains; and embedded links to actionable resources and follow-up guidance. The interactive tool is available on the operational DISCO platform [71].

Participants and Recruitment Process

Two groups of participants were recruited from the Groupe de Médecine de Famille Universitaire (GMF-U) of Saint-Hubert: (1) primary care clinicians and (2) parents or legal guardians of children who are patients of the GMF-U of Saint-Hubert. Purposive and convenience sampling strategies were used to ensure rich, relevant data while promoting in-depth discussion.

Clinicians were recruited through an internal invitation sent by the management of the family medicine clinic. Parents were recruited via email invitations relayed by clinic staff to those with upcoming appointments for children aged 2 to 12 years. Eligibility criteria included being a parent or legal guardian of a child in that age range and being fluent in French or English.

Data Collection

Three semistructured focus groups (August 2024, November 2024, and March 2025), each lasting 60 to 90 minutes, were conducted. Clinicians participated in person in August and virtually thereafter, whereas parents joined virtually in all sessions (via Microsoft Teams). Due to availability constraints, 8 sessions were held as individual interviews. One clinician and 1 parent participated in all 3 focus groups, whereas others joined a single session.

Discussions explored users' experience with the digital health tool; perceived usability and relevance of the prototype; satisfaction; and suggestions for content, format, and delivery (Multimedia Appendix 1). Iterative refinement of the tool was based on feedback collected throughout the sessions. For example, after the first session, visual mock-ups were developed based on user expectations; the second session focused on reactions to various features (eg, feedback messages); and the third session examined acceptability and emotional responses to the tool. All data were collected and analyzed in French and translated into English for reporting.

Data collection continued until thematic saturation was reached, defined as the point when themes became repetitive across groups and no new themes emerged during iterative coding. At this stage, participants' contributions reinforced and stabilized existing themes. In this study, saturation reflects internal coherence rather than statistical representativeness [72]. The same saturation criteria were applied to both parents and clinicians.

Data Analysis

All focus group recordings were transcribed verbatim and reviewed for accuracy. An iterative, hybrid analysis—combining inductive and deductive approaches—was conducted. Deductive codes were elaborated using a published framework covering 7 constructs of usability, acceptability, and satisfaction (affective attitude, burden, perceived effectiveness, ethicality, coherence, opportunity costs, and self-efficacy) [73]. Furthermore, initial coding involved open coding aiming to identify emerging meaning units (ideas, experiences, and suggestions), followed by axial coding to identify conceptual relationships and central themes.

Data were analyzed at the group level using thematic analysis to describe and interpret patterns of meaning [74]. The process was managed using Microsoft Excel. To ensure coherence and

XSL•FO
RenderX

transparency, the coder conducted systematic internal checks through repeated readings, comparison of the codes across cycles, and iterative refinement of the categories. Emerging themes were also discussed with the research team to strengthen analytic credibility [75]. Following a sequential cocreation approach inspired by the development of the RIPPLE pediatric obesity prevention tool [25,38,58,60], emerging themes from participants' feedback guided refinements to the tool, including clarifying content, improving ergonomics, and simplifying usability.

Ethical Considerations

This study received ethics approval from the research ethics boards of the Centre intégré de santé et de services sociaux de la Montérégie-Centre and the Sainte-Justine University Hospital Centre (application MP-04-2024-889 – DISCO – Focus Groups).

All participants provided informed consent prior to taking part and consented to the use and publication of their data. Each participant received a compensation of CAD $25 (US $18) per session.

Data were stored securely on the servers of Research Centre of the Sainte-Justine University Hospital Centre.

Results

Overview

Six discussions were conducted with a total of 8 participants, including 5 parents of children and 3 clinicians. Sessions were held either as individual interviews or dyadic discussions. All participants were female except for 1 clinician. Clinicians were family physicians with 5 to 6 years of professional experience. Participating parents had 1 to 3 children aged between 3 and 14 years.

Potential of the Digital Tool for Promoting Healthy Habits in Pediatrics

Parental Experiences With Digital Health Tools

Participating parents reported previous use of various digital tools to support their children's health, including platforms such as Dialogue (a telemedicine app) [76], smartwatches (for activity and sleep tracking), *Naître et grandir* (a government-sponsored parenting education website) [77], and *Rendez-vous santé Québec* (an online medical appointment–booking platform) [78]. Tools with simple, concrete guidance were particularly valued. One parent shared the following:

> *[The information is] written in a way that is very understandable for the general public, so it's very simple, very concise, with concrete examples.*

Several participants expressed concerns over tools perceived as overly commercial, simplistic, or lacking credibility. Some worried that digital tools disrupt the parent-child relationship:

> *I don't necessarily want a tool, a robot, to replace that connection with my child.*

They emphasized the importance of professional interfaces, quality assurance, and rigorous linguistic review in both French and English. One parent noted the following:

> *...small typos are fine, but blatant errors diminish the value of the questionnaire and makes it look less professional.... It makes the results seem less valid.*

Identified Needs for a Digital Tool

Parents described specific content needs for a digital lifestyle intervention tool, notably the desire for tailored guidance on complex topics such as eating behaviors and sleep challenges. They emphasized the following:

> *If you don't seek out information, you just do what you can, but you don't really know what the best practices are [...] [guidance] should come directly to us, you know, so we don't have to go looking for it.*

Clinician Perspectives on Automation and Screening

Clinicians generally supported automated lifestyle habit screening to reduce clinical burden. One stated the following:

> *In a perfect world, it wouldn't be the family doctor conducting lifestyle habit screening.*

They saw value in the tool providing personalized information while underscoring the importance of follow-up dialogue:

> *Our role is then to discuss how to apply it concretely in daily life [...] like motivational interviewing.*

Some participants supported broader automation, comparing the tool to mental health self-care platforms:

> *More programs designed to be accessible to the public, encouraging them to try self-care interventions. The more information you provide—especially if it's increasingly personalized and from reliable sources—the better. I fully support that.*

Implementation Challenges and Opportunities

Workflow Integration

Clinicians highlighted several barriers to completing the tool in the clinic. Filling it out in the waiting room was seen as unrealistic due to time constraints, late arrivals, and the difficulty of managing young children. Additionally, receiving results via email limited clinicians' ability to review them in time for the consultation.

To improve integration, clinicians strongly preferred embedding the tool in the electronic medical record, describing it as a straightforward and efficient solution. One noted the following:

> *...if it's a result [in the electronic medical record], [...] we have no choice but to read it, otherwise, it will always stay highlighted as an incomplete task note. This definitely encourages clinicians to check it out.*

Feasibility and Added Value in Clinical Practice of Use Prior to the Appointment

Participants agreed that it would be more practical to send the questionnaire before the appointment, ideally alongside the appointment confirmation, so that clinicians can review it

XSL•FO
RenderX

beforehand and tailor the visit. Some emphasized the importance of doing so even for walk-in visits, where vulnerable families may be reached unexpectedly:

> *That's often where we catch them, especially since parents usually come for regular check-ups up to the age of 3-4, and after that, we tend to lose them.*

This suggests that the tool could help maintain contact with families beyond early childhood, when routine follow-ups become less frequent.

Adherence to and Engagement With the Tool

Challenges

Maintaining long-term engagement, a prevalent issue in the digital health literature [79,80], was a shared concern. Both clinicians and parents noted that, after the age of 2 years, appointments become infrequent, making regular follow-up difficult. Motivation was seen as key: "I'd need to be fully committed," said one parent. Engagement also tended to decrease with subsequent children:

> *...it's nice when it's your first child [...] then parents lose interest.*

Clinicians saw value in a follow-up system to track engagement and identify families at risk of dropping off.

Suggested Solutions

Reminders Linked to Appointment

Implementing email notifications that encourage parents to schedule follow-up appointments to discuss lifestyle habits after long gaps between visits was suggested:

> *Email notifications could help.*

Involvement of Nurse Practitioners

As they often see families more regularly, they could reinforce messages and ensure continuity.

Motivational Prompts and Progress Tracking

Parents welcomed the idea of periodic check-ins:

> *[If I am] asked, "Do you agree to receive the link again in a few weeks to check your progress?" Then, yes, I'd definitely do it.*

Trusted Framing

Parents stressed the importance of the tool appearing credible and tied to a medical source (eg, physician's office or public health institution).

Multichild Usability

A suggested addition was the ability to complete the tool for more than one child at a time.

Perceived Limitations and Improvement of the Screening Tool

Sleep Habit Screening

Clinicians initially found the sleep section too limited, focusing mainly on duration with little attention to sleep hygiene. One noted that sleep problems often emerge indirectly, such as through academic or attention issues. A suggested addition was "Has the teacher reported any fatigue, sleepiness, or attention problems with your child?" to better capture underlying concerns.

Nutrition Screening

Both parents and clinicians found the initial emphasis on sugar-sweetened beverages (SSBs) too narrow. One parent noted the following:

> *There are many other aspects of nutrition that are more relevant to me than sugary drinks.*

A clinician also observed that dietary discussions often go beyond SSBs, pointing out that "Parents are very concerned about the amount of food that is eaten" and that "it's surprising how often families don't eat together."

Key nutrition-related challenges raised by parents included the following:

- Food exploration and parental education: exposure to disliked foods is still important, especially between the ages of 0 and 5 years
- Picky eating: a common source of stress in early childhood
- Time constraints and meal planning: balancing work and family limits time for healthy meals
- Teenager autonomy: teenagers make more independent and sometimes less healthy choices

Tool Revisions and Validation

After the first focus groups, the screening tool was revised to incorporate parent feedback. Sleep-related questions were revised to better capture sleep hygiene and overall sleep quality. While the original questionnaire included limited content, the updated version encompasses a broader range of dimensions, such as daytime sleepiness, napping patterns, regularity of bedtime routines and schedules, characteristics of the sleep environment (eg, independent sleep and presence of screens), sleep onset (autonomy and latency) and nighttime disturbances (eg, cosleeping behaviors). Similarly, the nutrition section was broadened to reflect overall dietary behaviors and the mealtime environment. Although it previously included a single item on SSB consumption, the revised version expanded to food-related behaviors and environment and, as such, included questions on meal regularity, family meal practices, dietary quality (eg, fruit, vegetable, and protein intake), beverage choices, screen use during meals, child involvement in food preparation, meal planning practices, and parental feeding strategies. Language was simplified, and examples were added for clarity (Multimedia Appendix 2).

In the second set of focus groups, these changes were well received. A clinician described the updated items as "excellent, very detailed," noting the following:

> *Eating behavior is really interesting. [...] [and] relevant.*

A parent highlighted the focus on "observable behaviors" and appreciated the educational aspect:

> *It tells me, "this is what a sleep routine is." It kind of educates me at the same time as giving advice.*

XSL•FO
RenderX

Feedback on Screening Report and Intervention

Presentation and Content of the Screening Results

Participants responded positively to the screening report's format and tone. Clinicians appreciated the inclusion of all behavior domains regardless of the results and the clear, color-coded layout:

> *Presenting all four sections, regardless of the results, is very positive [...] The positive approach to encouraging them and the available resources are very well designed.*

The tool was considered simple and accessible for most families. The report's emphasis on autonomy was also valued:

> *It's really good to let the parent decide which area they want to be informed about because having 3 or 4 areas to work on [can be a lot], [...] [this way, they can] take small steps on their own with your recommendations.*

Relevance and Usability of the Information

Parents appreciated receiving individualized and contextual data, especially charts comparing their children's behavior with national guidelines and clinic averages:

> *The comparative aspect is still fun, because we say we shouldn't compare ourselves, but at the same time, we all like to compare.*

However, the phrase "Top 10% of the clinic's most performing children" was criticized for being too competitive:

> *It should be about healthy lifestyle habits, not performance.*

Opinions varied on the level of detail in the graphs: some wanted more specificity (eg, types of activities, frequency, and age group distinction), whereas others felt that the current indicators (individual scores, recommendations, and averages) were sufficient. The relevance and appropriateness of within-clinic comparisons were also questioned by 1 participant.

Intervention and Resources

Participants valued the clarity, concreteness, and relevance of the resources. One parent said the following:

> *It's informative to know the impacts it has. The healthy goals. I also like seeing that, for example, the link for a tax credit provides information that we don't have. The resources are clickable on one of the links. It's very comprehensive, so it's interesting.*

They appreciated "immediate, applicable solutions," such as links to recipes or planning tools. Suggestions included practical tips for limiting screen time and integrating local resources by postal code (eg, green spaces and cycling paths). The intervention was seen as supportive of gradual, realistic change:

> *Sometimes it's nice to [...] take small steps by ourselves with the recommendations. I think that's the whole point.*

Overall, participants responded positively to the behavioral approaches included in the intervention.

Feedback on Encouragement Messages and Follow-Up

Tailored follow-up messages were seen as essential, particularly for families whose results did not improve. One parent noted the following:

> *...if [it has not worked] what can we do to help these families if it hasn't worked? [...] maybe we haven't seen improvements because you've maintained the same behavior. Did you know that there is another approach or reference?*

Personalized resources, whether to maintain progress or adjust strategies, were deemed essential to sustaining motivation.

Perceived Clinical Value and Opportunity Costs

Clinicians found the refined version of the tool efficient and user-friendly:

> *I really like that the recommendations for clinicians take only 20 seconds to read.*

Its brevity was seen as a strength that facilitated dialogue:

> *It opens the door for discussion.*

Both clinicians and parents viewed it as time-saving and accessible. One parent noted the following:

> *It's straightforward. [...] you don't really feel like filling out long tools while waiting in the clinic. I think you mentioned 15 minutes to complete it, but it felt more like 5.*

Clinicians highlighted three key strengths of the tool: (1) time savings ("It will save us time...and it aligns with a motivational interviewing approach since you've already started the work"), (2) initiation of the behavior change process ("prompting them to come with an answer, a rationale, or a potential solution at the next appointment. I think that could be beneficial"), and (3) increased parental engagement ("I think it's good to send this to all parents in any consultation context; I think it can be a good opportunity to just raise their awareness").

However, the tool's perceived value varied by family. Parents with prior knowledge or motivation felt that it might be too basic, whereas those with less awareness could find it overwhelming:

> *If it's for families who are already looking to improve behaviors, it might not go far enough for them. But for a family that really has no idea and needs to make changes, it might feel overwhelming.*

Discussion

Principal Findings

Through our focus groups aimed at refining our digital screening and intervention tool to promote healthy lifestyle habits in children, we found that the tool's key features, such as personalized, immediate, and normative feedback and access to concrete resources, were consistently valued by participants and align with known drivers of engagement and sustained behavior change [81,82]. Overall, parents reported feeling that the tool's questions were relevant and that the approach to offering support in behavior change and tailoring follow-ups,

XSL•FO
RenderX

as well as the resources offered, was helpful and acceptable. Clinicians found the refined version of the tool efficient and user-friendly, and while they expressed concerns about barriers to completing the screening in the clinic, they felt that it was relevant to use a tool of this nature to perform lifestyle behavior screening between appointments and that the data presented were insightful, especially as clinical follow-up becomes less frequent as children grow older.

The elements of the intervention that were guided by behavioral science principles, such as comparisons to peers and norms and personalized feedback, were well accepted by participants. The persuasive potential of behavioral sciences relies on modifying choice architecture (ie, the decision-making context in which individuals act [83]). These interventions aim to guide behaviors toward outcomes considered beneficial while preserving freedom of choice as no options are removed or restricted [84]; therefore, guiding behaviors without unduly influencing or exerting coercive pressure that may limit informed decision-making [85]. In our development of the tool and implementation of strategies from behavioral science frameworks, we carefully considered the balance between behavioral effectiveness and respect for autonomy [86] and, through our focus group discussions, ensured that we elicited any autonomy-related concerns from stakeholders about the intervention; none were raised.

Overall, our study highlights the potential of a codeveloped digital tool for screening and promotion of healthy lifestyle habits in pediatric primary care. The participatory approach enabled iterative refinement based on clinicians' and parents' input, ensuring high acceptability, usability, and relevance (Multimedia Appendices 2 and 3).

While the integration of stakeholders supports participatory design, organizational factors such as timing of distribution, follow-up mechanisms, appointment coordination, and communication between families and professionals must be addressed for effective clinical implementation. These align with known implementation challenges in feedback-based interventions, where mode, frequency, and source of feedback influence the impact [87]. Future phases of this research project will leverage the early insights gleaned in this study and seek to address them to elucidate the most effective path forward.

As mentioned by participants, equitable access remains challenging, especially for families facing structural barriers (eg, financial constraints, fragmented services, and logistical difficulties). To address this, the tool was codeveloped with parents and clinicians, and tailored strategies with concrete support were prioritized to reduce contextual barriers and foster engagement [88]. Still, the recruitment process may have introduced selection bias as participating clinicians were likely more engaged in lifestyle-related screening and some parents may have been more motivated or available. The small sample size of this study and the self-selected nature of participants (all from a single clinical site) further limit the generalizability of the tool in development.

This could limit the tool's applicability to less engaged or more vulnerable populations—the very groups for whom equitable access is most critical. However, the primary objective was to gain insights into key concepts essential for tool development rather than produce exhaustive results. Future phases of this program of research will involve implementing and evaluating the tool in more generalizable settings, including through open-label testing in larger and more diverse populations, and using the screening and brief intervention tool to facilitate access to lifestyle behavior screening, all while collecting data on feasibility and acceptability from a more diverse population, leading to eventual implementation in clinical and other pediatric settings.

Verbatim translation from French into English may have introduced bias; efforts were made to preserve meaning within feasibility constraints [89]. Additionally, the sample size and the mix of focus groups and individual interviews may have influenced interaction dynamics, although the consistency of perspectives across formats strengthens the credibility of the findings [90].

Despite these limitations, this study lays a strong foundation for future work. Subsequent phases will include a feasibility study and broader engagement with stakeholders to assess the tool's adaptability. This will be followed by a pilot study and a randomized controlled trial to rigorously evaluate the tool's effectiveness in improving pediatric health outcomes.

Conclusions

To our knowledge, no similar preappointment screening tool exists in general pediatric care. This study provides early evidence on the feasibility and relevance of a codeveloped digital tool to promote healthy lifestyle behaviors in pediatric primary care. Its participatory design and user-valued features support its potential for future evaluation and implementation. This work represents the initial phase of its development. Future phases of the project will evaluate tool completion rates, repeat engagement, uptake across clinic-specific instances, and workflow integration metrics. Secondary outcomes will include changes in parent-reported child lifestyle behaviors across physical activity, sleep, nutrition, and screen time domains. These next-stage outcomes are guided by the broader implementation principle that, while there are an increasing number of validated tools and evidence, dissemination remains a major barrier to real-world reach and impact. In this context, infrastructure determines equity and access, and future phases will specifically assess the scalability of deployment across various settings, including pediatric clinics, family medicine groups, and nonclinical environments such as schools and community centers, particularly to reach children and families who may not otherwise have timely access to traditional care settings [91].

Abstract

Background: Available information about existing neonatal and pediatric intensive care datasets is scarce.

Objective: The objective was to evaluate the feasibility of a monocentric high-frequency dataset of neonatal and pediatric intensive care patients in a cohort study.

Methods: This study included patients treated in the neonatal and pediatric tertiary care intensive care unit at Uniklinik RWTH Aachen, Germany. The dataset comprised high-frequency data on bedside monitoring and ventilation, CO_2 monitoring, laboratory results, important diagnoses and interventions, patient characteristics, and manual annotations (including procedures, eg, intubation and X-rays; and states and illnesses, such as episodes of apnea of prematurity and patient-ventilator asynchronies).

Results: In total, 400 admissions (227 neonatal and 173 pediatric) from 359 patients were included between September 2024 and January 2026. Of these, 28 neonates were extremely preterm, 34 were very preterm, 68 were moderate to late preterm, and 97 were term infants, with an overall median gestational age of 35 (IQR 31-38) weeks and a median birth weight of 1805 (IQR 1446-3251) g. The pediatric population comprised 34 infants aged younger than 1 year, 45 toddlers aged 1 to 5 years, 43 children aged 6 to 12 years, and 51 adolescents aged 13 to 18 years, with a median age of 10.6 (IQR 1.2-13.0) years and a median admission weight of 22 (IQR 11-50) kg. Overall, 77% (400/517) of all eligible patients were enrolled in the study. The dataset comprised 3600 patient days with more than 20,000 manual annotations (approximately 3 TB) and has been used for multiple use cases.

Conclusions: The high temporal resolution allows for detailed characterization of patient states. To our knowledge, there are no published descriptions of comparable European high-frequency neonatal or pediatric intensive care datasets. We share information about our dataset to encourage cross-institutional cooperation. The multicenter pooling of data or federated learning increases possible use cases by enabling new research questions or the development of more robust algorithms.

Introduction

Approximately 12% of neonates and 13% of hospitalized children require treatment in an intensive care unit (ICU) [1,2]. Although there have been advances in neonatal and pediatric research in the last decades, many common treatment strategies are still not evidence based [3]. Scientific findings from studies in adult populations are rarely validated on pediatric data [4].

XSL•FO
RenderX

Furthermore, they often cannot be transferred to pediatric patients due to substantial differences in pathophysiology [5]. Despite frequently unknown risks, this results in the widespread off-label use of medication, accounting for up to 50% of prescriptions [6]. This gap of knowledge is particularly problematic because childhood is a critical period for disease development, with long-lasting implications on personal health [7,8].

Neonatal and pediatric intensive care research is challenged by a heterogeneous patient population (eg, with a wide weight range) and small sample sizes [9-11]. Ethical considerations, legal frameworks, and parental uncertainty often obstruct study participation [12]. It can be conflicting to find a balance between protecting the most vulnerable patients by avoiding stress associated with clinical trials on the one hand and obtaining scientific evidence for adequate therapies on the other hand [13]. This leads to recruitment challenges with limited funding and persistently low study enrollment of less than 50% of eligible patients [14-16].

Secondary data research refers to the use of preexisting data that were collected for other purposes and are reused for scientific investigations [17]. It is time-, cost-, and resource-efficient and often faces fewer bureaucratic obstacles than experimental studies [18]. Among others, data can be used for complication detection, clinical decision support, quality analysis, and individualized medicine [19]. It can be helpful in gaining a deeper insight into the effects and side effects of off-label treatments [20]. Despite their advantages and the opportunity to address a variety of unanswered research questions, secondary data are still underused [21].

Data storage solutions for high-frequency intensive care data (such as the Philips Data Warehouse Connect) have been commercially available for almost a decade and are increasingly used. It can be assumed that this is also true for pediatric and neonatal intensive care data, although only very few such datasets are openly available. The storage capacity of these systems exceeds that of *conventional* patient data management systems (PDMSs) by several orders of magnitude. It allows for storing not only numerical but also waveform data at sampling frequencies up to 500 Hz. In turn, this enables researchers to reconstruct critical clinical situations at a high temporal resolution. We established a Data Warehouse Connect system and conducted a study of our pediatric and neonatal patient cohort beginning in August 2024. With regard to data composition, pediatric and neonatal intensive care treatment is characterized by above-average lengths of stay and relatively low patient counts [22]. This poses a dilemma for data research: the limited patient numbers demand cross-institutional data pooling for many research questions [23]. At the same time, low patient counts make it particularly difficult to comply with data protection requirements for anonymized data such as k-anonymity [24]. Our institutionally approved data protection concept therefore demands only sharing anonymized data with third parties for defined purposes with a restricted user circle under contractual protection. The execution recommendations of the Technology and Methods Platform for Networked Medical Research e.V. also advise against the disclosure of anonymized data in public-use files unless “based on general life experience or the current state of scientific knowledge, it is practically impossible to link the data to a specific individual” [25]. The primary objective is to publish the dataset. We hope that, as we move closer to concepts such as the European Health Data Space—including the needed underlying legal perspective—we will be in a position to make the data available to the community in the future. Until then, we see collaborative research as a viable option. This approach allows AI algorithms to be trained independently at different locations using locally available data, such that only model parameters are shared and no explicit patient data are exchanged; this approach is known as federated learning [26]. Another option is to perform external validation for the developed algorithms.

We present our project and metadata with two objectives: (1) to enable potential collaboration partners in our field to determine the extent to which our data and research activities align with their own and (2) to demonstrate that meaningful secondary data analysis can be conducted under the challenging conditions of contemporary neonatal research, even in single centers, and to motivate others to engage in this field [27].

Methods

Study Design

AIx-Neo-Guard is a collaborative project of the neonatal and pediatric ICU of Uniklinik RWTH Aachen, Germany, and the Chair of Embedded Software of RWTH Aachen, Germany. The project is conducted as an observational cohort study and was prospectively registered at the German Clinical Trials register (DRKS00033228). The study is conducted in accordance with the Declaration of Helsinki [28] and the STROBE (Strengthening the Reporting of Observational Studies in Epidemiology) statement guidelines for reporting observational studies [29]. Data collection started in September 2024 and has no scheduled end date.

Ethical Considerations

The study was approved by the local ethics committee (Ethik-Kommission an der Medizinischen Fakultät der Rheinisch-Westfälischen Technischen Hochschule Aachen [RWTH Aachen]; approval EK 24-213). The German Health Data Utilization Act grants an exemption from individual parental informed consent, as only data that are regularly used for diagnostic and therapeutic purposes are collected. Openly available information about ongoing studies at an institution needs to be provided to enable the exemption, and parents can actively revoke study participation.

Setting

Data are collected at the neonatal and pediatric tertiary care ICU of Uniklinik RWTH Aachen, Germany. The ward offers 9 beds, each equipped with the capability to provide respiratory support. Annually, approximately 350 patients aged 0 to 17 years are treated on the ward.

Participants

All eligible patients treated in the ICU are included in the dataset. Patients are excluded if their parents object to data

XSL•FO
RenderX

processing or study participation. Furthermore, technical issues can lead to unintended exclusion.

Variables

The dataset incorporates monitoring and ventilation data, laboratory results, patient characteristics, selected diagnoses and interventions, and manual annotations. An overview is given in Table 1. Waveform data are stored at 125 Hz, except for electrocardiogram (ECG) data, which are stored at 500 Hz. Numerical data are recorded with a sampling rate of 1 Hz.

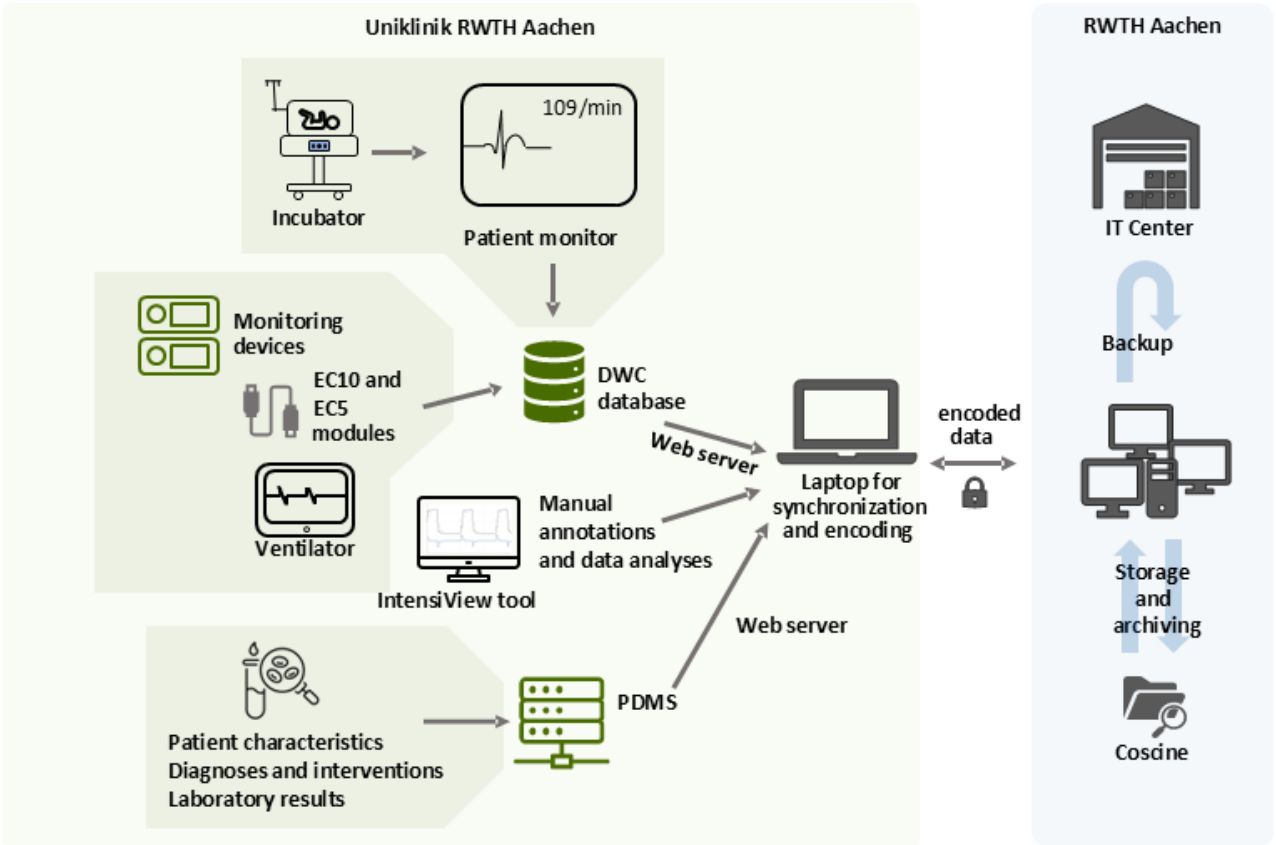
[d]PDMS: patient data management system.



Data Sources and Management

The bedside monitoring is conducted using a Philips IntelliVue X2 monitor (all Philips devices provided by Philips GmbH Market DACH) connected to an IntelliVue MP70 monitor. A Sentec Digital Monitor with V-Sign sensor (SENTEC AG) is used for transcutaneous CO_2 monitoring. Ventilatory support is supplied by a Leoni plus or Elisa ventilator (Löwenstein Medical). The ventilators and CO_2 monitoring are connected to the bedside monitoring using Philips IntelliBridge EC5 ID modules connected via a local area network cable to IntelliBridge EC10 modules. EC10 modules are connected to the monitor by a module rack M8048A. All monitoring and ventilation data are retrieved after storage from the Philips Patient Information Center iX using Philips Data Warehouse Connect, version C.03.

Parameters derived from the PDMS (CGM Medico [CompuGroup Medical SE and Co KGaA]) are extracted manually and retrospectively added to the dataset. These comprise patient characteristics (eg, admission weight and sex), diagnoses, laboratory results, body positioning, and interventions (imaging, intubations and extubations, operations, and nursing care). Results from manual data analyses are annotated using a project-intern visualization and annotation tool (refer to the IntensiView Tool section). These annotations included patient-ventilator asynchronies, apnea of prematurity, exact time of blood sampling, disconnection of ventilators or monitoring devices, or suctioning.

All data, including timelines, are stored in a coded form in a database hosted by the Chair of Embedded Software. The hospital intern patient identifiers are encoded using a randomly generated 32-character universally unique identifier. The encoding table is stored in an access-protected file at Uniklinik RWTH Aachen and only accessible to clinical investigators. A data flowchart is provided in Figure 1.

XSL•FO
RenderX

IntensiView Tool

The IntensiView tool (RWTH Aachen University) is a project-specific software developed by the Chair of Embedded Software. The tool is developed in C++ using the Qt Framework to easily deploy across operating systems. A PHP-based backend is used to communicate with the database. IntensiView is used for data synchronization, visualization, annotation, and export. Visualization can be adapted to the user's requirements by changing colors, adapting the number of plots with freely selectable axes, and switching between column and line diagrams. The annotations can then be added manually or automatized using detection algorithms and are inserted into the database. A screenshot is shown in Figure 2.

An annotation search tool enables the user to reload episodes with specific annotations directly. All data can be exported in CSV format. Additionally, external time-series data and annotations can be easily imported and visualized.

A plug-in interface offers standardized access to the data loaded in the IntensiView tool to integrate new functionality, such as detection algorithms that support current research questions. The tool offers a variety of plug-ins for data analyses, for example, an ECG analysis tool, parameter calculation (eg, mean and median, calculation of airway volume curve from the flow curve, and calculation of airway resistance and compliance from ventilator pressure and flow waveform data), and the creation of ventilator loops.

Figure 2. Screenshot of the IntensiView tool for the visualization, annotation, and export of clinical data.

Bias

We included all eligible patients to avoid selection bias. All patients were treated according to local standards. The study participation did not alter diagnostics and treatment. Monitoring and measurements were conducted by the same type of measuring devices in all patients to minimize detection bias.

Study Size

The aim was to include all neonatal and pediatric intensive care patients at Uniklinik RWTH Aachen. Due to limited staff resources, short-stay patients may sometimes not be included because they are discharged before a clinical investigator can link their patient identifiers with the corresponding patient data.

Quantitative Variables

The following variables were stored in a categorized fashion: sex, age or gestational age, admission weight, admission weight percentile, and type of annotation.

Statistical Methods

Descriptive statistics, including medians, IQRs, and frequency distributions, were computed to characterize the dataset. No inferential statistical analyses were conducted. Statistical analyses were performed using SPSS (version 29.0.0.0; IBM Corp).

Data Access and Cleaning Methods

Only the clinical investigators who were directly involved in patient treatment had access to the linking file with the identifiers and were able to access the decoded data at all times. The other project partners had unlimited access to the coded dataset.

After synchronization, the data were reviewed for completeness and consistency. Data cleaning involved identifying missing or incomplete values, ensuring consistency across variables, and resolving any discrepancies. Data anomalies, such as outliers (eg, *z* scores >3), were detected manually or by statistical means. Where appropriate, missing data, duplicate entries, and outliers were removed prior to analyses.

Linkage

Data were not linked across multiple databases.

XSL•FO
RenderX

Results

There were 517 ICU admissions during the study period (17 months as of January 27, 2026). Of these, 117 admissions could not be included due to technical issues (primarily Data Warehouse Connect downtime or faulty linkage between intern patient identifiers and Data Warehouse Connect) or missing linkage between patient identifiers and patient data, resulting in a dataset comprising 400 admissions from 359 individual patients.

In total, 227 admissions were attributable to neonatal patients. Of these, 28 were extremely preterm (<28 weeks), 34 very preterm (28+0 to 31+6 weeks), 68 moderate to late preterm (32+0 to 36+6 weeks), and 97 term (≥37 weeks). In total, 173 pediatric admissions were included (34 infants aged <1 year, 45 toddlers aged 1-5 years, 43 children aged 6-12 years, and 51 adolescents aged 13-18 years).

A total of 57.8% (231/400) of admissions were contributed by male study participants. Of the 359 patients, 31 (8.6%) had multiple admissions and 9 (2.5%) had more than 2 admissions. Mortality was 3.6% (14/400) in the study cohort. Median length of stay was 2 (IQR 1-8) days. In total, approximately 3600 patient days were incorporated in the dataset. Patient characteristics are shown in Table 2.

More than 20,000 annotations were added manually to the dataset. The most frequent annotations are active expiration against the ventilator (n=4083, 20.4%), nursing (n=2926, 14.6%), ineffective efforts during expiration (n=1221, 6.1%), apnea of prematurity (n=1271, 6.4%), and time of medical imaging (sonographies: n=185, 0.9% and X-rays: n=153, 0.8%).

So far, the dataset comprises 3 TB of data (implemented using MariaDB as the database management system) and has been used for multiple research questions. A high time resolution was required to address these subjects. An overview is given in Table 3.

Table 2. Patient characteristics.

	Neonatal	Pediatric	Total
Number of admissions, n/N (%)	227/400 (56.8)	173/400 (43.3)	400/400 (100)

Discussion

Key Results

In this collaborative project, we successfully established a monocentric high-frequency database of neonatal and pediatric intensive care patients. The dataset incorporates 400 admissions with a total of 3600 treatment days and more than 20,000 manual annotations. We store data from bedside monitoring, ventilation, laboratory results, patient characteristics, and a variety of manual annotations. There is currently no published description of comparable European high-frequency datasets for neonatal and pediatric intensive care patients.

Interpretation

There are various existing databases incorporating neonatal or pediatric ICU data. Many of these databases contain patient-level data but do not provide high-frequency data [36]. The Pediatrix BabySteps Data Warehouse is a large database of more than 1 million neonatal patients [37]. It contains patient data and characteristics recorded on a daily basis. Many of these data are also included in our database. We collect a variety of additional variables, many of which are captured with high temporal resolution at the second or subsecond sampling levels.

Previously published intensive care databases have paved the way for secondary data analyses. The most commonly used datasets are the Medical Information Mart for Intensive Care-III (MIMIC-III) and MIMIC-IV databases [38,39]. These databases contain medical and demographic data from more than 350,000 ICU patients and have been used in more than 2000 secondary data analyses [40]. However, pediatric patients only constitute a small proportion of the MIMIC-III cohort and were completely excluded from MIMIC-IV. The MIMIC-III Waveform Database [41] extends the clinical data from MIMIC-III by waveform data from approximately 30,000 ICU patients, including 7870 neonates. However, only a subset of these recordings has been matched with the clinical data from MIMIC-III [42]. Comparing the IDs from the matched subset with the original one, we found only 6 neonatal patients with both clinical and waveform data.

Specific pediatric datasets exist: the Pediatric Intensive Care database, for example, incorporates data from more than 12,000 neonatal and pediatric patients [43]. Among others, it provides vital signs, medications, laboratory measurements, and lengths of stay. However, these are stored at low recording frequencies (ie, at 1-minute intervals). The investigation of pathophysiologic conditions often benefits from much higher data resolutions [44].

An example of such a high-frequency dataset is the Preterm Infant Cardio-Respiratory Signals Database [45]. It incorporates 1.6 GB of high-resolution data of ECG and chest impedance from 10 spontaneously breathing premature infants. However, the small sample size and restricted parameter set limit its potential applications.

For pediatric patients, a Canadian group established a database of approximately 1200 patients treated in a pediatric ICU [46]. The researchers collected data at higher frequencies compared to other available databases. The data were recorded every 5 seconds from the bedside monitors and every 30 seconds from the ventilators. This represents a major advancement for research

XSL•FO
RenderX

involving high-frequency data. However, this time resolution does not allow a reconstruction of waveform data such as ECG or the airway pressure waveform. In previous analyses, we developed algorithms for detection of ineffective efforts during expiration. They constitute one of the most prevalent forms of patient-ventilator asynchronies [47] and result in prolonged mechanical ventilation and length of stay [48]. The detection algorithms are based on synchronous breath-by-breath waveform analyses of airway flow, which requires a very high time resolution. To the best of our knowledge, there are no descriptions of neonatal or pediatric datasets that can provide high-frequency data with an equivalent parameter set for a comparable sample size in Europe.

An approach for collecting high-frequency data was developed for The Hospital for Sick Children in Toronto, Canada, establishing a new data collection system for waveform storage and retrieval [49]. The database used (AtriumDB) holds waveforms from more than 5300 patients. The paper focuses on the technical development and compression techniques, giving only a short overview of the available data. Furthermore, only waveform data were stored through the described setup, without additional data relevant for intensive care.

Besides the high-resolution monitoring and ventilation data, the AIx-Neo-Guard dataset incorporates important diagnoses, laboratory results, patient characteristics, and manual annotations. This enables a detailed reconstruction of patient states and dynamic physiological changes. In particular, machine learning approaches benefit from such a dataset. The large number of manual annotations can be used to train detection algorithms for highly relevant complications. Furthermore, the unlabeled data can be used for unsupervised or self-supervised learning approaches to detect anomalies, identify clusters, or train foundation models. The integration of high-frequency physiological signals with clinical variables offers an important platform for clinically meaningful and translational research. The dataset opens important opportunities toward outcome-oriented research and enhances pathophysiologic understanding [50]. For example, using detection methods for ineffective efforts based on waveforms together with information on the patient's state can deepen our understanding of the effects of patient-ventilator asynchrony on the patient's outcome.

Limitations

The most important limitation is the single-center study design. First, it limits the available study population. Furthermore, diagnostic and treatment practices are based on local standards, which may introduce institutional and performance bias. We are preparing to collaborate with other centers to increase the available data and reduce the influence of local practices. Joint research across institutions is also desirable to allow the validation of algorithms (eg, for clinical decision support) on external data. This can contribute to enhancing the generalizability of results derived from a particular dataset.

So far, the dataset does not incorporate all relevant information on diagnostics and treatment. Fluid management and medication, for instance, are not yet integrated into the parameter set. Furthermore, the duration, for example, of nursing care is not labeled. This, in turn, is a current limitation for the possible use cases of the dataset. Predictive modeling and causal inference often require this valuable information to provide reliable estimates. The legal framework and ethics approval permit the storage of all variables related to diagnostics and treatment in the ICU. We extend the number of collected parameters continuously and plan to incorporate fluid management and medication data in the future.

Due to the rapid growth of data, there are insufficient staff resources to manually annotate the full dataset. The annotations are continuously extended and improved to enhance the quality of data. The set of annotations may furthermore also be enhanced by automated annotation using machine learning approaches. As previous analyses specifically focused on respiratory events, respiratory annotations are overrepresented compared to nonrespiratory annotations. These annotations will have to be made prior to use for nonrespiratory use cases. The data quality is furthermore hampered by technical issues. Occasionally, the ventilator fails to connect to the central monitoring interface. Resolving this issue would require restarting the ventilator. However, during mechanical ventilation, such an intervention would not be ethically justifiable because it could jeopardize the safety of critically ill patients. Similarly, the patient identifiers must be linked to the patient data on the bedside monitor to include the patient in the dataset. The limited staff resources do not allow a clinical investigator to be present at all times to carry out this step. This problem therefore systematically affects short-stay patients who require only short-term treatment or observation (such as those with transient tachypnea of the newborn, those recovering from operative procedures, or those admitted for intoxications). These episodes result in missing valuable data. This introduces a relevant selection bias toward more severe and longer-stay patients and has an impact on the representativeness of the dataset. Specifically, the overrepresentation of infants with longer or more severe courses will influence descriptive analyses and downstream modeling based on this cohort. As a result, findings derived from this dataset should be interpreted as reflecting the subset of neonatal ICU patients for whom complete data capture was feasible, rather than the entire admitted population.

Finally, the dataset was established to promote secondary data analyses. Secondary data research is always prone to bias due to unmeasured confounding and missing data. As the data were collected for a different purpose, the available data do not always meet the requirements of a specific research question, for example, if parameters of interest are missing. In these cases, other data sources must be sought. We hope to reduce this source of bias by pooling data with other centers in the future, increasing the set of available parameters, and continuing data collection and annotation. While secondary data research can support evidence-based medicine, interventional trials are sometimes still necessary.

Future Work

We are currently working on machine learning algorithms to automatically detect and correct time stamps for nursing rounds and blood sampling. These are the first steps toward an

XSL•FO
RenderX

automated improvement of data quality, as these interventions inevitably lead to data anomalies, such as noisy ECG.

To further extend the dataset, information from pregnancy medical history is currently being integrated into the database for all neonates. In the future, the dataset will be further enriched with microbiological data (eg, results from blood cultures) and more comprehensive information on fluid management and medication administration. This will help improve the interpretability and increase the number of research questions that can be addressed using the dataset.

By sharing these database descriptions, we hope to encourage cross-institutional cooperation and invite all interested researchers to contact us, for example, to conduct external validation of algorithms. We hope that collaborations will promote the multicenter pooling of data and thereby enhance the available data. Larger study cohorts and datasets can improve statistical power and are particularly important for investigating rare diseases, for which adequate sample sizes are often difficult to achieve in single-center studies.

Using federated learning could also leverage the described dataset without the need for direct data sharing. Federated data access enables privacy-preserving development of AI algorithms across institutions and could create a pathway toward more robust foundation models for neonatal and pediatric intensive care.

Conclusions

We successfully established a monocentric high-frequency neonatal and pediatric intensive care dataset. The available data have been used for various use cases, with further analyses ongoing. Secondary data research can substantially reduce the need for experimental studies and contribute to evidence-based medicine. We hope that ongoing European Union legislation (European Health Data Space) will create a legal framework for the multicenter pooling of data. This would represent a major advance, as it could rapidly increase the available data, counteract bias, and thereby expand research opportunities and improve generalizability.

Abstract

Background: Pediatric patient care portals through electronic health records (EHRs) provide opportunities to enhance patient care. However, challenges exist for making portals usable, and few studies have examined qualitative experiences of caregivers when using integrated primary care (IPC) services for their children.

Objective: This study aimed to qualitatively examine barriers to and facilitators of using electronic patient portals in integrated behavioral health care.

Methods: Data were collected from 7 caregivers of pediatric patients (0-7 years old) during focus groups. Interview data were analyzed qualitatively and coded by an interdisciplinary group. An iterative approach identified overarching themes within the following Consolidated Framework for Implementation Research (CFIR) domains: outer setting, inner setting, and characteristics of individuals.

Results: Overall, caregivers found the portal beneficial. Six themes emerged during thematic analysis. Outer setting themes were “lags and barriers to care” and “connections with outside providers.” Inner setting themes were “putting the ‘human’ in ‘human-centered design’” and “virtual access to information.” Characteristics of individuals themes were “flexibility” and “personalization.”

Conclusions: The current study sheds light on caregiver perceptions of electronic portal use. Patient portals are an effective and well-received tool for patients with developmental delays and families accessing behavioral health information. Future targets for improvement include personalization, equitable access, and reach beyond single institutions.

KEYWORDS

electronic patient portal; integrated primary care; developmental behavioral pediatrics; pediatric primary care; health equity; behavioral health

Introduction

Facilitating between-visit communication between pediatric care providers and patient caregivers improves patient outcomes across various pediatric conditions [1,2]. Effective and accessible mechanisms facilitate pediatric care provider and patient communication, particularly in the delivery of interdisciplinary care [3] given the multiple providers involved in coordinating care. Integrated primary care (IPC) links behavioral health care clinicians to medical physicians through the embedded delivery of prevention, assessment, and treatment services [4]. IPC services can be colocated appointments, delivered within the context of scheduled medical visits, and/or implemented through communications and supports between

XSL•FO
RenderX

visits. Many integrated service delivery models rely on features within the electronic health record (EHR) to improve engagement, increase adherence, and open lines of communication between pediatric care providers and caregivers [5-7]. However, previous research has found that traditional primary care EHR systems may not have all the capabilities that behavioral health clinicians need, such as the ability to track behavioral health goals, administer electronic behavioral health screeners, and communicate effectively with other primary care physicians [8,9]. The absence of these functionalities may disrupt workflows and could lead behavioral health care clinicians to keep their own records outside of the EHR [10]. Modalities of virtual care have become widely used across health systems in the wake of COVID-19 and play a particularly important role in the delivery of behavioral health services [11].

With greater access to technology, patient care portals embedded within the EHR have been increasingly used as a mode of communication between pediatric care providers and caregivers. Embedded EHR portals are typically an "opt-in" electronic space where patients, patients' caregivers, and pediatric care providers can communicate with other medical providers and staff regarding scheduling, nonurgent medical concerns, laboratory findings, orders, and referrals. It has been estimated that 60% of health care systems implement portals as an element of patient care and communication [12]. Patient adoption rates of portals were estimated to be 15% to 30% and growing following the COVID-19 pandemic, representing an area of promise for health care communication [12,13]. The American Academy of Pediatrics has highlighted the potential of EHRs to improve patient access to health information, facilitate preventative health, and support disease management [14]. In the context of IPC, portals can play an important role in screening; assessment; and facilitating aspects of care such as communication with multiple physicians involved in care, the provision of links to video visits, and a means of connecting patients with applications for symptom monitoring [8]. EHR portals tend to be well received by patients and caregivers, who endorse ease of use [15] and high ratings for satisfaction [16,17].

Despite the utility and ubiquity of patient portals in pediatric care, challenges exist in the uptake and reach of portal technology among underrepresented and marginalized patient populations [18]. Such inequities have been documented among economically disadvantaged and racialized groups [13,19]. For example, African American families and children on Medicaid are less likely to have a portal account set up when available [20]. There is limited research on the potential barriers to portal use among marginalized patient groups. Understanding how families navigate health care communication and their perceived benefit from technology in the delivery of health care may help make health care technology more accessible and user-friendly. Creating an EHR that works effectively for all medical and mental health care clinicians in integrated practices can be difficult [21]. Patient voices are often left out of the conversation when institutions make decisions about the adoption and implementation of patient-facing platforms [22], which may perpetuate or amplify existing disparities in pediatric behavioral health care [23]. User experience designs highlight that user voices can be leveraged to more readily align technologies with user needs, desires, and goals.

The current study aimed to begin filling in gaps in understanding marginalized patients' and caregivers' qualitative experiences with patient care portals when used in the context of IPC service delivery and developmental screening. We hypothesized that caregivers and families experience both barriers to and facilitators of portal-based care at the systemic, institutional, and individual levels. By identifying root causes of barriers and facilitators at each level, this work can inform the development of a multilevel toolkit to facilitate patient access to care and serve as a first step in research to refine EHR experiences for IPC.

Methods

Setting and Overall Study Design

This study was a collaborative effort that included clinician researchers across multiple service delivery divisions, including IPC, developmental behavioral pediatrics (DBP), and general pediatrics. This study took place in a culturally and ethnically diverse primary care clinic at a Midwest academic medical center. Most families served within the clinic depend on publicly funded insurance and face many barriers to care (ie, financial, social, logistical, and cultural). The setting included the use of a patient portal that allowed families to receive notifications about appointments, access clinical care through video visits, schedule and reschedule appointments, send and receive messages to and from pediatric care providers, complete behavioral health questionnaires before their visits, request their medical record for mental health appointments, submit release of information forms for outside medical and school providers to talk with third parties (eg, schools and mental health clinics), and access resources (eg, patient education materials and community mental health resources). A qualitative research design was used involving focus groups to explore participants' perceptions and experiences, allowing for in-depth discussions and identification of shared themes and insights. We used the Consolidated Criteria for Reporting Qualitative Research (COREQ) guidelines to ensure a rigorous qualitative methodology [24]. Data were coded, analyzed, and interpreted using the Consolidated Framework for Implementation Research (CFIR) [25] to provide a structured approach for identifying key factors influencing the implementation of the patient portal across both internal and external systems of care.

Procedures

CFIR

Focus group questions were developed, and qualitative analyses were conducted using the CFIR. The CFIR is a flexible framework that is adaptable to a variety of study methods. The CFIR includes 5 constructs: intervention characteristics, outer setting, inner setting, characteristics of individuals, and process. The study team identified 3 CFIR domains that were most relevant to this study: outer setting, inner setting, and characteristics of individuals. As this study did not analyze the effects of an intervention, the other 2 domains (ie, intervention

XSL•FO
RenderX

characteristics and process) were not included in the qualitative analysis.

The focus group questions centered on facilitators and barriers in the outer setting, inner setting, and characteristics of individuals domains. Questions were open-ended and probed about caregivers' experiences and preferences as well as facilitators of and barriers to their children receiving care, especially those related to the use of the patient portal. The focus group questions were developed using an iterative process: each interview informed the script for the following focus group to delve deeper into different areas mentioned by the previous groups.

Recruitment

We completed a retrospective chart review of the EHR from January 2023 to March 2023 to identify families with children aged 0 to 7 years who had received IPC or DBP care to inquire about participation in this study. Families from this chart review and other patients who were suggested by IPC and DBP providers were contacted via phone call to determine their interest in participating in this study. The IPC and DBP clinics were embedded in a racially and ethnically diverse clinic with approximately 66% of children served by Medicaid. This clinic is affiliated with a Midwestern academic medical center. Families were then approached via phone call with a research assistant and provided with study details and next steps for participation if interested. Our sample, therefore, included participants from multiple recruitment methods and a convenience sample of interested families. Caregivers who expressed interest in participating were given the option of taking part in in-person or virtual groups, and they provided their preference for time of day. Given that this study was institutional review board exempt, caregivers verbally assented to the study via phone and were enrolled after indicating that they would like to participate in the study.

Inclusion criteria were caregivers with 1 or more children receiving behavioral health services (IPC or DBP), aged 0 to 7 years, and who were perceived as having a behavioral or developmental concern needing more care as identified by a pediatric care physician. Exclusion criteria were caregivers who did not speak or understand English sufficiently.

In total, 28 caregivers were approached via phone about participating in this study, of whom 16 (57.1%) indicated that they would like to attend. Groups were formed by matching caregivers' modality (ie, virtual or in person) and time of day (morning, midday, or afternoon) preferences. Three to 6 caregivers were scheduled for each focus group. Caregivers were contacted via phone to provide focus group details and confirm that the date and time worked for their family. A total of 87.5% (14/16) of the caregivers confirmed that they were able to attend one of the focus group offerings. The caregivers were called the day prior to the focus group to ensure that it still worked for their family. Of the 14 caregivers who confirmed, 7 (50%) completed interviews, and 7 (50%) who were scheduled for interviews did not attend. It is unclear why these 7 caregivers were unable to attend. The research assistant attempted to call the families 10 minutes after the focus group began to ask them whether they needed assistance logging on to the virtual link. The groups took place from January 2023 to April 2023.

Focus Groups

An in-person focus group and 2 virtual focus groups were led by a parent advocate and community partner trained in reflective practices, whereas the third virtual focus group was led by the research assistant. The parent advocate told the participants that their passion for helping on this project came from their own children with disabilities and their desire to help other families receive the medical care they needed for their own children. The in-person focus group took place at a local library, whereas the virtual focus groups were conducted from wherever the caregivers desired. The parent advocate and research assistant were given interview guides with sample questions and prompts that were created by the authorship team. Two children were also present at the in-person group along with 2 researchers. As the Zoom (Zoom Video Communications) focus groups took place wherever the caregivers desired, there may have been other individuals listening who were not directly involved in the focus group. Each participant engaged in a single focus group.

All focus groups were recorded and transcribed. The virtual focus groups were video recorded, whereas the in-person focus group only recorded audio. Field notes were taken both during and after the focus groups. Transcripts were not returned to participants for comment and/or correction. Interested caregivers were placed in focus groups based on availability and modality preference (in person vs virtual). A Zoom link was sent to the primary email of the caregivers participating in the virtual focus groups. After low attendance to the first virtual focus group, caregivers in the subsequent groups received a reminder email 1 week before, a reminder call within 48 hours of the focus group, and a call 10 minutes after the focus group began if they were not on the Zoom link to double-check whether the technology was working. In some cases, the Zoom link needed to be resent. After families were identified for inclusion in the study, a chart review was conducted to determine the children's race and ethnicity, age, sex, and insurance provider.

Ethical Considerations

This study was overseen by the University of Michigan Institutional Review Board (HUM00215154) and was deemed "not regulated." Caregivers provided verbal consent upon scheduling the focus groups. At this time, they were informed that this was an optional qualitative improvement project and that they could leave or withdraw from the study at any time. Researchers deidentified transcripts; the transcripts were housed in a secure, protected health information drive; and any documents containing protected health information were password protected. Caregivers were also notified that their information would be deidentified when the findings were published. Participants received a US $60 Visa gift card for taking part in this study.

Qualitative Analysis

The CFIR was used to categorize responses relevant to implementation in combination with grounded theory methods to allow novel themes to emerge. After each focus group, the

XSL•FO
RenderX

research team met as a group and independently read the transcripts to discuss major themes that emerged from each relevant CFIR domain. A coding tree was developed within the CFIR domains, with 2 themes per domain. The research team consisted of 3 physicians (MD), 2 licensed psychologists (PhD), and 1 research assistant. Two of the physicians were developmental behavioral pediatricians, and 1 was a primary care pediatrician. The 2 PhD psychologists were integrated behavioral health psychologists. The research assistant was a PhD candidate in clinical psychology. All members of the research team identified as women, were from a diverse range of backgrounds (Asian, Black, Middle Eastern, and White), worked at an academic medical center, and had experience working on qualitative research within IPC. The participants knew that the researchers consisted of physicians and psychologists within an academic medical center. The focus group transcripts were read by all 6 researchers to create themes and identify example quotes. Two researchers (one of the physicians and one of the psychologists) returned to the transcripts to code for themes iteratively. Following each focus group discussion, we discussed the conceptual depth of themes and agreed through collaborative consensus. After completing 4 focus group interviews, it was decided that adequate conceptual depth and data saturation were achieved. Data were managed in Microsoft Excel. The outer setting domain involves how well the institution connects and communicates with outside referrals and agencies. For this study, many barriers were identified in the outer setting, including structural barriers to accessing the portal and portal resources. The inner setting domain details how well the institution connects and communicates within the organization. Many strengths were identified in the inner setting, including benefits and opportunities for portal use. The characteristics of individuals domain included aspects of caregivers' own preferences or personality that aided or hindered portal use and their preferences for communicating with pediatric care providers through the portal. Many structural barriers existed for caregivers' participation in this study, contributing to a small sample size. However, in the tradition of qualitative research, high information power was achieved through the narrow aim, dense specificity, use of an applied theory, strong dialogue, and case analysis [26].

Results

Overview

One in-person and 3 virtual 90-minute focus groups were hosted involving 7 caregivers of children 2 to 7 years of age. One focus group only had 1 caregiver attend, but the other 3 had multiple caregivers in attendance. All 7 caregivers were female. The children receiving behavioral health services were of Black (n=3), White (n=3), and other (n=1) races. (see Table 1 for demographic information). Participants provided feedback to the research team about clinic changes that they would like to see.

Table 1. Electronic medical record demographic information (N=7).

Variable	Participants, n (%)
Patient age (y)	
2	1 (14.3)
3	1 (14.3)
4	1 (14.3)
5	2 (28.6)
6	0 (0)
7	2 (28.6)
Child sex	
Male	3 (42.9)
Female	4 (57.1)
Child race	
Black	3 (42.9)
White	3 (42.9)
Other	1 (14.3)
Insurance	
Public	1 (14.3)
Private	6 (85.7)

Caregivers generally described positive experiences with the portal, which helped them better access their children's health care and connect with their behavioral health care clinicians. Caregiver access and comfort with their children's patient portal was revealed as the most influential variable to their behavioral health care experience. Caregivers who could access their children's EHR portal shared that they liked the ability to schedule and see appointments, receive appointment reminders,

XSL•FO
RenderX

and communicate with pediatric care providers. Conversely, parents who identified portal access as a barrier reported difficulties using technology and limited access due to their children's age and/or their caregiver status. Overall, 6 themes were identified, which we categorized into the outer setting, inner setting, and characteristics of individuals domains of the CFIR (Table 2).

XSL•FO
RenderX

Table 2. Themes and constructs with example quotes.

Construct	Description	Example quotes
Outer setting		
Lags and barriers to care	This theme emerged as a concept that referred to systemic factors shaping caregivers' access to care.	• "...if you have to call for an appointment, a lot of times with the call center you have to wait or they transfer me to the wrong people and then I spend easily an hour on the phone trying to figure out what his appointment is or following up on a referral that didn't get placed." • No portal access for foster parents: "And because they're not fully adopted, they are not allowing me to use the portal. And not being able to use the portal is unfair from my standards...." • Rescheduling leading to delays in services: "It could be long, long wait times to get another appointment back. It could be six weeks, it could be eight weeks.... And especially with early intervention, because with early intervention, every day lost is a day you can't get back."
Connections with outside medical and behavioral health providers	This theme referred to caregivers' desire for care coordination between medical and behavioral health providers using the EHR[a] patient portal.	• "I'm a fan. In fact, I think that there should be like a universal one [portal system], because it shouldn't be.... That's the one hassle I've had. And I get like why these privacy laws are there and whatnot.... Can we streamline this please and make life simple for everybody?"
Inner setting		
Putting the "human" in "human-centered design"	This theme refers to the various ways in which the portal can be used as a tool for medical information, accessing pediatric care providers, and coordinating their children's care.	• "I do [use the portal], as much as possible. That's why I don't want to go see a doctor anywhere else because it makes my life easy." • Difficulties with setting up the portal: "What I don't like about it is I just had my son and nobody has showed me how to sign up for the portal. I mean, they gave me a piece of paper, but I'm like, I'm a more show me type person, so show me how to access this patient portal."
Virtual access to information	This theme refers to the overarching ways in which families seek information on the internet to make medical decisions.	• Parent describing behavioral health videos sent through the portal: "Because at least the video is easy to you just watch and you can follow what their actions. I mean, it's just my own opinion."
Characteristics of individuals		
Flexibility	This theme emerged from caregivers' desire to have a responsive medical system that suits each unique family system.	• "I like in-person just 'cause I mean, I feel like if it's relating to my kid, she probably needs to be present and she's not going to be present for a virtual meeting. [Chuckle] That's not going to happen." • "And she called me at home before the holiday and said, 'I just wanna make sure, is there anything else? Did you think about what I said? Is there anything more for you? How he is....' And my heart just melted. I said she didn't have her nurse or you know, some other person. She called me. I felt like so great."
Personalization	This theme emerged from caregivers' need for tailored and individualized care.	• "That's an interesting question. I think it's probably situational specific because what if it's something I have questions about, or what if it's something that requires a dialogue for understanding? Because this is all.... Even though I'm in it for like two and a half plus years now, it's still new territory to me. I'm learning every day about my child and what she needs and how to help her and how to deliver it, and the best delivery method and mode that she responds to that's best for her. So if it's like a social activity I would almost think social instruction would be, whether it's over the phone or by video...would be super beneficial. And but if it was something more like, little tips or tricks for improving fine motor skills, I would see how a worksheet delivered through the portal would be suffice."

[a]EHR: electronic health record.

RenderX

Outer Setting Themes

In the outer setting, themes identified were "lags and barriers to care" and "connections with outside medical and behavioral health providers." Lags and barriers to care emerged as a concept that referred to systemic factors shaping caregiver access to care. Caregivers generally viewed the portal favorably to reduce the lags and barriers to care, such as allowing for easy scheduling and rescheduling of appointments, but some families were not provided with equitable access, especially those providing care for foster children. Some of the lags and barriers to care were mentioned 11 times during the focus groups and included long waits for the call center, no portal access for foster parents, and delays in care when parents needed to reschedule appointments. The lags and barriers to care were perceived as critical. For example, a caregiver stated the following:

> *...with early intervention, every day lost is a day that you can't get back.*

As represented by the theme "connections with outside mental and behavioral health providers," caregivers reported a strong desire for care coordination between pediatric care providers using the portal and included difficulties and lengthy intake processes with outside referrals as major barriers to care. Outside medical and behavioral health providers included Early On, applied behavior analysis therapy, behavioral therapy, community mental health, and other outside behavioral or developmental services. One caregiver wished there was a "universal" portal system:

> *Can we streamline this process and make life simple for everybody?*

Connections with outside medical and behavioral health providers were mentioned 6 times during the focus groups.

Inner Setting Themes

In the inner setting, the themes identified were "putting the 'human' in 'human-centered design'" and "virtual access to information." The "putting the 'human' in 'human-centered design'" theme refers to the various ways in which caregivers can use the portal as a tool for medical information, accessing pediatric care providers, and coordinating their children's care. This theme included statements about how the portal is an effective tool and ways in which it could be more tailored to meet families' needs. One caregiver even noted the following:

> *I do [use the portal], as much as possible. That's why I don't want to go see a doctor anywhere else because it makes my life easy.*

The theme of putting the "human" in "human-centered design" was identified 8 times throughout the focus groups. When 1 caregiver had difficulty getting ahold of someone to help them log into the portal, they mentioned missing behavioral health care visits. Virtual access to information refers to the overarching ways in which families seek information online to inform medical decisions. It was identified 12 times during the groups and included how caregivers access information about their children's health care, including information sent through the portal, such as websites with behavioral health information, and a desire for behavioral health providers to send behavioral health parent training videos. Without information provided through visits or the portal, parents stated that they would refer to social media.

Characteristics of Individuals Themes

Themes identified in the characteristics of individuals domain were "flexibility" and "personalization." Flexibility was conceptualized as the desire to have a responsive medical system that suits each unique family system and was mentioned 6 times during the focus groups. Some parents preferred visits to be in person, whereas others preferred them to be virtual. One caregiver mentioned that it was very challenging to bring her child to an in-person behavioral health visit, whereas another caregiver mentioned that it was difficult to get her child to sit still for a virtual behavioral health visit. Personalization was conceptualized as the caregiver's need for tailored and individualized care for their child and was mentioned 10 times during the focus groups. One caregiver noted the following:

> *Well, I know what's best 'cause I'm the parent. I'm the one dealing with it. But I want them [medical and behavioral health providers] to feel heard and I wanna feel heard. I wanna come to a good compromise.*

Whatever method of communication (in person, virtual, phone, or portal message), parents want personalized care that fits their children and families. Caregivers seek flexibility and personalization in their care, and the portal can either help facilitate these goals or hinder them depending on how it is designed and used.

Discussion

Principal Findings

To our knowledge, this is the first study of its kind to use the CFIR to better understand caregiver-reported facilitators and barriers surrounding accessing and using patient care portals in the context of pediatric IPC. The purpose of this investigation was to gather information for the development of a streamlined behavioral health toolkit that will guide institutional policies and procedures surrounding the use of patient-facing EHR tools to improve patient care. The current study is the first to our knowledge to examine caregiver perspectives on the use of a patient EHR portal for pediatric IPC, finding that caregivers believe it is a useful tool but there continue to be access issues to the portal.

Overall, the caregivers included in this study viewed the patient care portal as a positive space to participate in care for their children, in particular, helping meet needs within the context of the health system (inner setting). Structural barriers and inequities in caregiver access to electronic behavioral health records were also reported across participants, particularly surrounding care coordination and the need for more tailored and individualized care.

Using the family voice in our study design allowed for the identification of human-centered design principles to inform potential improvements in the patient and caregiver experience. Caregiver-reported positive interactions with the portal fell primarily within the inner setting domain of the CFIR, which

XSL•FO
RenderX

suggests that, at the individual patient level, the portal aids in effective communication between caregivers and pediatric care providers. Specifically, the patient care portal was helpful in aiding caregivers' scheduling of appointments and their access to clinical care services such as video visits. Families also reported accessing health information on social media and through other open online sources, suggesting that future portal integration of health care information from trusted resources may be an area that families may find beneficial. Ultimately, families perceived the patient portal as an effective bridge to health care access. However, families often differed in their preference for virtual vs in-person care and communication of behavioral health needs.

A structural barrier commonly reported by participants was the problem of lengthy wait times to be able to schedule or reschedule behavioral health services when having to go through call centers. The patient portal, however, was perceived as something that helped increase access to care and reduce wait times. Prior work using time use diaries has found that low-income families are more likely to spend an additional 12 minutes per day waiting for services compared with their higher-income counterparts [26]. One potential mechanism might include a dearth of medical and behavioral health providers accepting Medicaid [27], which limits caregiver access to medical care overall. In this study, families indicated that the patient portal was one way to bypass long waits in the call center and that it was the more ideal way to reschedule care. Patient portals may be an important way to accommodate the time constraints of low-income families, whose employment may not have substantial flexibility to address scheduling and make phone calls during regular clinic hours.

Another area of potential future innovation that should be considered is developing capabilities to allow for communication across pediatric care providers and institutions. Families noted that systems-based communication between pediatric care providers and early intervention or community mental health was lacking, but a portal system that was universal and not institution specific could facilitate warm handoffs and referral monitoring between disparate systems. For example, the patient portal could display referral status across systems to create continuity and personalization of care, which families valued and desired.

Finally, an important barrier identified by caregivers was the lack of universal accessibility of the patient portal to foster parents. The number of children in foster care has increased from approximately 397,000 in 2012 to 442,000 in 2017 [28]. Children in foster care experience increased health problems compared to the general population and may require more extensive communication with their pediatric care providers [29]. For this population, there may be multiple encounters with the health care system in many settings and with many caregivers, leading to fragmented care [30] and complicating the communication of critical health information [31]. There is promise in leveraging the patient portal to create a more streamlined system to detangle health care delivery among children in foster care. Recognizing this gap in service delivery, Texas; Cincinnati, Ohio; and Allegheny County, Pennsylvania, have passed laws or created data systems that improve health care communication for children in foster care. Lessons learned from these regional efforts could be used to inform how health systems can incorporate more inclusive policies to allow foster parents to have portal access for services and features that can facilitate patient care while maintaining protection and privacy of patients in state custody.

Our study had several limitations. As a single-center study, our work may not be generalizable to other populations using different EHR portal systems or in other states with different regulations regarding foster care or privacy. In addition, data were qualitative and included a small number of participants. Patient perspectives may not reflect the views of other populations. Strengths of this study include the specificity of behavioral health information and inclusion of a low-income and racialized population, who experience greater barriers to health care and access. Future research should explore caregiver education on features and functions of the patient portal, as well as how policy changes can help caregivers better access behavioral health information, provide a more positive experience regarding scheduling appointments, and be more inclusive.

Conclusions

Using in-depth qualitative methods, we found that a patient portal is an effective and well-received tool for patients accessing behavioral health information. Despite positive perceptions, ways in which these tools can be personalized and reach beyond single institutions were identified as potential areas of improvement. It was also evident that disparities remain in health IT access that require systemic work to ensure that all populations have access to high-quality care, streamlined communication, and behavioral health information.

Abstract

Background: Low birth weight (LBW) is associated with increased risks of neonatal morbidity, developmental delays, and long-term health problems. Although baby massages have been shown to improve growth and neurodevelopmental outcomes in LBW infants, access to suitable training and adherence to massage protocols remain challenging, particularly in low-resource settings. Mobile health interventions may help address these gaps by providing scalable and standardized education on infant massage.

Objective: This study aimed to design and evaluate a human-centered baby massage mobile app to support the growth and development of LBW infants in Indonesia.

Methods: A human-centered iterative design approach was used to develop the mobile app. Usability was assessed using the System Usability Scale among 42 caregivers of LBW infants. Qualitative data were collected through semistructured interviews and analyzed thematically to understand user experience. A pilot pre-post intervention study was conducted to evaluate the impact of the app on caregivers' knowledge, confidence, adherence to baby massage practices, and infant growth outcomes. Pre- and postintervention measures were compared.

Results: The app demonstrated high usability, with a mean System Usability Scale score of 78.6 (SD 8.2), indicating good usability (≥68). Most participants rated the app as "excellent" or "good." Qualitative findings highlighted improved caregiver confidence and ease of learning massage techniques. Statistically significant improvements were observed in caregiver knowledge (mean difference 20.5 points; *P*=.002), confidence (21.6 points; *P*=.001), and adherence to recommended massage practices (20.3 points; *P*=.02). Infant outcomes also improved, including weight gain (mean increase 330 g; *P*=.003) and head circumference (mean increase 1.3 cm; *P*=.004).

Conclusions: The human-centered baby massage mobile app showed promising feasibility and effectiveness in improving caregiver knowledge, confidence, and adherence to infant massage practices. The app provides a culturally appropriate and user-friendly tool to support early interventions for LBW infants in resource-limited settings.

Introduction

Low birth weight (LBW), defined by the World Health Organization as a birthweight less than 2500 g, remains a substantial global public health challenge [1]. LBW is a critical indicator of neonatal morbidity and mortality, with an estimated 15% to 20% of all births worldwide classified as LBW, representing more than 20 million births annually [2]. The burden of LBW is prevalent in South Asia and sub-Saharan Africa, with 44% and 28% of LBW cases globally, respectively [3]. In Indonesia, the prevalence of LBW ranges from approximately 6% to 10% of all live births, according to national health surveys and global estimates [4,5]. LBW can pose several health risks for infants, such as stunted growth, neurodevelopmental delays, and an increased risk of infections and chronic diseases [6,7]. Such challenges underscore the urgent need for effective interventions to mitigate the long-term sequelae associated with LBW.

Existing interventions for LBW infants can be divided into methods such as kangaroo mother care (KMC) [8,9] and those that use modern technology [10-12]. KMC refers to holding the infant in skin-to-skin contact with the caregiver and has been widely adopted in low- and middle-income countries because of its practicality and effectiveness [8]. However, its reliance on continuous physical contact can be impractical for caregivers, especially in resource-limited settings. Complementary nonpharmacological techniques, including baby massages, have potential benefits, but this procedure usually necessitates training and routine practice, which often remain inaccessible [13].

Baby massages, a form of touch intervention, have shown promise in promoting health outcomes for LBW infants. Research indicates that massage can enhance weight gain, support neurodevelopment, and strengthen the emotional bond between infants and caregivers [14-18]. Randomized controlled trials and systematic reviews further suggest that infant massage significantly improves weight gain and neurobehavioral development in LBW infants [19-22]. Despite these benefits, barriers such as a lack of trained health care providers and inconsistent app by caregivers limit its widespread adoption.

The therapeutic benefits of baby massages in neonatal care are well documented. As a nonpharmacological approach, it promotes vagal nerve stimulation and facilitates improved digestion and increased weight gain [23]. Moreover, it promotes neurodevelopment through enhanced sensory integration and modulation of stress hormones [18,20,24]. Baby massages promote emotional bonding, which is crucial for the psychological development of the infant [22]. Studies have demonstrated that it enhances digestive and immune functions and reduces levels of stress hormones in infants and parents alike [23,24]. It is also involved in critical motor and sensory development, especially in premature and term infants [16]. However, in low- and middle-income countries, structural challenges make it difficult to find and use baby massages, including health care infrastructure and sociocultural obstacles [25]. The diversity of massage techniques and cultural practices also creates challenges in its implementation, highlighting the importance of standardized training and evidence-based guidelines [26,27]. In Indonesia, the limited availability of relevant and culturally sensitive educational materials has been a major obstacle to its adoption.

The rise of mobile health (mHealth) has shown promise in improving parental knowledge and compliance with neonatal care practices [28,29]. Parents have been encouraged to practice KMC and monitor infant growth through some mobile apps [11,12]. Such tools have also been shown to support prenatal care, breastfeeding, and early childhood development, and to improve parental confidence, adherence to health recommendations, and child health outcomes [29-31]. Studies show that mobile apps with interactive and user-centered features can be associated with higher user satisfaction and improved maternal health behaviors [32]. However, despite the increasing use of mHealth technologies, there is a significant lack of literature describing mHealth for baby massage education, particularly in multiculturally diverse contexts [33].

In many cases, existing mHealth apps are unable to implement human-centered design principles vital for usability and engagement, particularly in the Indonesian context [34]. Additionally, few evidence-based, culturally appropriate interventions exist to address the specific needs of LBW infants and their caregivers [35,36]. Little is currently known about the factors influencing the digital classroom experience in this field, including opportunities for bias against visual assets, as most research around baby massage education and experience continues to rely on face-to-face instructional culture. This creates a major gap in knowledge concerning how effective mHealth apps can be in increasing the knowledge, skills, and confidence of parents to perform baby massages [33]. Evidence is limited regarding infant health outcomes or how usability features may influence user engagement, satisfaction, and long-term adherence [34].

Filling these gaps is essential for informing scalable, accessible, and effective interventions targeting diverse populations. To ensure the development of such clinically meaningful mobile apps, we need a user-centered design process, complemented with a solid evaluation framework [34]. This study aims to address these gaps by developing and evaluating a human-centered baby massage mobile app designed to enhance growth and development in LBW infants in Indonesia.

Methods

Study Design

This study used a mixed methods design consisting of (1) usability testing and (2) a single-arm pilot pre-post intervention study conducted over 4 weeks.

The usability phase evaluated user experience (UX) and system performance using the System Usability Scale (SUS) and qualitative interviews.

The pilot phase used a 1-group pretest-posttest design to assess changes in caregiver knowledge, confidence, adherence to baby massage practices, and infant growth parameters following exposure to the mobile app.

XSL•FO
RenderX

No control group was included in this pilot study, as the primary objective was to assess the feasibility, usability, and preliminary effectiveness.

Participant Recruitment and Sample Size Rationale

Participants were recruited between January and March 2025 through community health centers, pediatric outpatient clinics, and online announcements distributed via maternal health networks in West Java, Indonesia.

Eligibility criteria included the following: being a primary caregiver (mother or father) of an infant with documented LBW (<2500 g), infant age between 0 and 12 months, ownership of an Android smartphone, and ability to read Bahasa Indonesia.

Caregivers of infants with congenital abnormalities or severe medical instability were excluded.

The sample size (N=42) was determined based on recommendations for pilot feasibility studies, which suggest 30 to 50 participants to estimate preliminary effect sizes and usability metrics. The sample was also considered adequate for detecting moderate pre-post effects using paired statistical testing.

Overview

A human-centered iterative design framework guided the development and evaluation of a mobile app designed to optimize growth and development in LBW infants through baby massages. The app design and development process was broken down into 6 clear steps, each contributing to the app definition and validation process.

Stages of App Design and Development

Overview

The development of the baby massage mobile app followed a systematic, human-centered design framework, resulting in a functional and user-friendly tool. The process was iterative, consisting of six development cycles that produced six progressively refined versions of the app. Each iteration incorporated user feedback to improve usability, content, and functionality. A brief description of each stage is presented in the subsections below.

Stage 1: Establishing the Study Team

A multidisciplinary team was established, comprising neonatologists, pediatricians, child development experts, mobile app developers, and UX designers. The team also included pediatric nurse specialists, nursing researchers, and software engineers.

Regular meetings were conducted to ensure alignment among team members, foster interdisciplinary collaboration, and integrate clinical insights with technical perspectives. These meetings also facilitated knowledge exchange across disciplines and supported systems thinking, which helped define the project's scope, objectives, and technical approach.

Stage 2: Defining a Set of App Design Requirements

The app design requirements were informed by a comprehensive literature review and expert consultations. Academic databases were systematically searched for peer-reviewed articles, systematic reviews, and clinical guidelines related to LBW infants, baby massages, and mHealth apps (PubMed and Google Scholar; publications up to October 2023). Records published since 2019 were emphasized to ensure relevance and alignment with current best practices. We extracted findings on effective interventions, user preferences, and technological features and identified gaps in the literature, specifically for culturally tailored digital solutions for LBW infants in low-resource settings. These efforts were further complemented by consultations with neonatologists, pediatricians, child development specialists, and UX designers to inform screen design requirements. Several key features emerged: step-by-step tutorials for baby massages, progress tracking, reminders, and culturally relevant content. These requirements were based on evidence-based practices and adapted to the specific needs of LBW infants and their caregivers [37].

Stage 3: Defining User Requirements

Focus group discussions (FGDs) were conducted with caregivers of LBW infants and health care providers to identify user requirements. The discussions explored users' preferences, challenges, and expectations regarding a baby massage app.

Participants emphasized the need for a simple and intuitive interface, clear visual guidance, and offline functionality, particularly to accommodate limited internet access in rural settings [38].

Stage 4: Creating the App Prototype

In addition to instructional videos, interactive guides were incorporated to enhance user engagement. These guides allowed caregivers to access additional information, such as diagrams and animations, to better understand massage techniques and their benefits. The design emphasized intuitive navigation and responsive feedback to support ease of use.

A growth tracker feature was also included to enable caregivers to monitor infants' development. The dashboard displayed key indicators such as weight and head circumference in an easy-to-read format, allowing users to visualize progress over time.

The prototype was developed as a set of wireframes representing the app's layout and structure. Design tools such as Figma (Figma, Inc), Adobe XD (Adobe Inc), and Sketch (Sketch BV) were used to visualize the interface, typography, and icons through semi-interactive mock-ups.

Stage 5: Expert UX Review

A panel of experts in neonatal care, digital health, and UX design conducted a comprehensive review of the prototype. The panel included neonatologists with expertise in LBW infant care, clinicians experienced in mHealth apps in low-resource settings, and UX designers specializing in usability and user engagement.

The review process was structured and began with an initial briefing session, during which the prototype's features, design principles, and intended user journey were presented. Experts then evaluated the prototype based on predefined criteria,

XSL•FO
RenderX

including usability, functionality, visual design, sustainability, and cultural relevance.

Feedback from the experts led to refinements in several areas, including navigation clarity, instructional content, feature integration (eg, instructional videos and dashboard), and cultural appropriateness for the target Indonesian users.

Stage 6: Testing the Prototype

Usability testing and pilot testing were conducted to assess the refined prototype in real-world conditions.

Usability Testing

We conducted usability testing with 42 caregivers of LBW infants recruited from a tertiary care hospital in Indonesia. Respondents who were willing to download and evaluate the app were included in the study sample. To evaluate the app's usability, we used the SUS, which produces scores from 0 to 100. A higher score indicates improved usability. Furthermore, qualitative feedback on UX was collected via semistructured interviews [39]. We provided participants the app prototype and asked them to perform tasks such as finding a tutorial, setting reminders, and tracking their progress. Observations of users' interactions with the app, along with feedback collected through the SUS and interviews, were analyzed. Quantitative data from the SUS were analyzed using descriptive statistics, and thematic analysis was applied to the qualitative data.

Pilot Testing Phase

The pilot study used a single-arm pre-post design and was conducted among 42 caregivers of LBW infants from various socioeconomic backgrounds in Indonesia.

Knowledge, confidence, and adherence to baby massage practices were assessed using preintervention and postintervention questionnaires. The instrument, known as the Caregiver Baby Massage Knowledge, Confidence, and Adherence Questionnaire, was developed by the research team, comprising neonatologists, pediatricians, child development specialists, and nursing researchers.

The questionnaire development followed an iterative process, including a literature review on baby massage practices and caregiver self-efficacy, as well as expert consultation in neonatal care and digital health. The final instrument consisted of 30 items across three domains:

1. Knowledge (10 items)—assessing caregivers' understanding of baby massage techniques, benefits, and precautions
2. Confidence (10 items)—measuring caregivers' perceived ability to correctly and consistently perform baby massages
3. Adherence (10 items)—evaluating compliance with recommended baby massage routines

Items in the confidence and adherence domains were scored on a 5-point Likert scale ranging from 1 (strongly disagree) to 5 (strongly agree). Knowledge items were scored as 1 (incorrect) or 5 (correct). Domain scores were calculated by summing item scores, with higher scores indicating better knowledge, confidence, or adherence.

The questionnaire was translated into Bahasa Indonesia and validated in a preliminary study involving 30 caregivers. Reliability testing demonstrated good internal consistency, with Cronbach α values of 0.88 (knowledge), 0.90 (confidence), and 0.86 (adherence).

Intervention Procedure

During the 4-week intervention period, caregivers were instructed to use the mobile app as their primary guidance tool for baby massage practice. Specifically, caregivers were asked to perform the following tasks:

- Watch instructional baby massage videos within the app at least 3 times per week
- Perform baby massage sessions at home at least once daily (minimum 5 sessions per week)
- Log massage completion in the app after each session
- Record infant weight weekly using digital baby scales available at community health centers
- Enter infant growth measurements, including weight and head circumference, into the in-app growth tracking feature

The app provided automated daily reminders to encourage adherence. All instructional materials were accessible offline after initial download.

No biochemical or laboratory biomarkers were assessed. Infant outcomes were limited to anthropometric measurements, specifically weight and head circumference.

Information regarding caregiver responses, app use patterns, and infant growth parameters was collected at baseline and after completion of the 4-week intervention. The mobile app for baby massages was developed as a functional prototype (Figure 1).

XSL•FO
RenderX

Figure 1. Mobile app for baby massages.

Statistical Analysis

Paired *t* tests (2-tailed) were conducted to compare preintervention and postintervention outcomes for caregiver knowledge, confidence, adherence scores, and infant growth parameters. Statistical significance was set at $P<.05$.

Ethical Considerations

This study was approved by the institutional review board of STIKep PPNI Jawa Barat (III/045/KEPK/STIKep/PPNI/Jabar/XI/2024). All participants provided written informed consent prior to participation. Participants did not receive financial compensation for their participation in the study. Caregivers were informed of their right to withdraw at any time without consequences. All collected data were anonymized and stored securely in password-protected databases.

Results

Demographic Characteristics of Participants

The study included 42 caregivers of infants aged 0 to 12 months. The demographic characteristics of the participants are presented in Table 1. Most of the participants (n=35, 83.3%) were mothers with an average age of 29.5 (SD 5.2) years. Most participants had a university-level education (n=31, 73.8%) and were first-time caregivers (n=25, 59.5%). Nearly all participants (n=40, 95.2%) had no prior experience with baby massage.

XSL•FO
RenderX

Table 1. Demographic characteristics of participants (N=42).

Characteristic	Values, n (%)
Gender	
Female	35 (83.3)
Male	7 (16.7)
Age (years)	
<25	10 (23.8)
25-34	27 (64.3)
≥35	5 (11.9)
Education level	
High School	8 (19)
University	31 (73.8)
Postgraduate	3 (7.1)
First-time caregiver	25 (59.5)
Prior baby massage experience	
Yes	2 (4.8)
No	40 (95.2)

Usability Testing Results

Table 2 presents the descriptive statistics for the SUS scores. The mean SUS score was 78.6 (SD 8.2), indicating a high level of usability. Most participants (85%) rated the app as "excellent" or "good" for ease of use and navigation. The highest-rated aspect was "ease of learning" (mean score 4.5; 5-point scale), while the lowest-rated aspect was "visual design appeal" (mean score 3.9; 5-point scale; Table 2).

Table 2. Descriptive statistics for usability testing using the System Usability Scale.

Usability metric	Value
Overall System Usability Scale score, mean (SD)	78.6 (8.2)
Ease of navigation, mean (SD)	4.3 (0.7)
Ease of learning, mean (SD)	4.5 (0.6)
Visual design appeal, mean (SD)	3.9 (0.8)
Task completion rate (%)	92
Error rate (%)	5.2

Qualitative Feedback From Users

Thematic analysis identified key themes related to usability, functionality, aesthetic design, user satisfaction, and cultural relevance. Table 3 summarizes the themes, categories, and example quotes.

XSL•FO
RenderX

Table 3. Thematic analysis of user feedback.

Theme and category	Example quote
Usability	
Ease of use	"I found the app very easy to navigate, and I didn't need much time to learn how to use it."
Clarity of features	"The app's instructions are clear, but some icons could be more intuitive."
Intuitive navigation	"The app is very easy to use. I found the tutorials and reminders without any difficulty."
Functionality	
Reminder system	"The reminder feature is very helpful in ensuring I don't forget my baby's checkups."
Tracking progress	"I like how I can track my baby's weight and feeding schedule in one place."
Informative content	"The videos and interactive guides taught me how to massage my baby properly. I feel more confident now."
Aesthetic design	
Visual appeal	"The design is good, but a more colorful interface would make it more engaging."
User satisfaction	
Overall experience	"I would recommend this app to other parents; it makes managing my baby's health much easier."
Cultural relevance	
Local language support	"I appreciate that the app is in Bahasa Indonesia. It makes it easier for me to understand."
Culturally appropriate	"The massage techniques shown in the app are similar to what my mother taught me. It feels familiar and comfortable."

Pilot Testing

Caregivers demonstrated a significant increase in knowledge about baby massage techniques and their benefits, with a mean improvement of 20.5 points (P=.002). Confidence levels among caregivers improved significantly, with a mean increase of 21.6 points (P=.001). Caregivers reported feeling more capable of performing baby massage correctly and consistently. Adherence to baby massage practices improved by 20.3 points (P=.02), indicating that caregivers were more likely to follow the recommended massage routines after using the app. Infants showed significant improvements in weight (mean increase of 330 g; P=.003) and head circumference (mean increase of 1.3 cm; P=.004), suggesting positive effects of the intervention on infant growth and development (Table 4).

Table 4. Preintervention and postintervention outcomes for caregivers and infants.

Outcome measure	Preintervention, mean (SD)	Postintervention, mean (SD)	Mean difference (SD)	*P* value
Caregiver knowledge	65.2 (8.5)	85.7 (6.3)	20.5 (7.1)	.002
Caregiver confidence	60.8 (9.2)	82.4 (7.8)	21.6 (8.3)	.001
Adherence to practices	55.3 (10.1)	75.6 (8.9)	20.3 (9.5)	.02
Infant weight (grams)	2200 (150)	2530 (140)	330 (120)	.003
Infant head circumference (cm)	32.5 (1.2)	33.8 (1.1)	1.3 (0.9)	.004

Discussion

Principal Findings

This study assessed the effectiveness of a human-centered mobile app designed to support the growth and development of LBW infants in Indonesia through baby massages. The app achieved a high usability rating, reflecting its user-friendly design and ease of navigation.

Postintervention evaluations showed significant improvements in caregivers' knowledge (P=.002), confidence (P=.001), and adherence to baby massage practices (P=.02). Importantly, infants whose caregivers used the app demonstrated significant increases in weight (P=.003) and head circumference (P=.004), indicating positive effects on their growth.

The app's high usability and positive user feedback highlight its success in addressing the needs of its target audience. Caregivers praised its intuitive interface, clear instructions, and culturally relevant content, which were designed to reduce cognitive load and enhance engagement. Features such as the reminder system and progress tracking were particularly valued, as they supported consistent massage routines and enabled caregivers to monitor infant growth. These findings align with human-centered design principles, which emphasize tailoring digital health solutions to users' needs and contexts [33,34,40,41].

While the app's usability was generally high, minor concerns regarding visual design and icon intuitiveness suggest areas for future improvement. This study builds on these insights by introducing a culturally tailored, human-centered app

XSL•FO
RenderX

specifically designed for Indonesian caregivers, addressing a gap in the literature.

The findings corroborate prior research on the benefits of baby massages and mHealth interventions for LBW infants. For instance, Vickers et al [16] reported that baby massages enhance weight gain and neurodevelopment in LBW infants, while Knop et al [28] highlighted the role of mHealth interventions in improving parental education and adherence to neonatal care practices. Similarly, Bangor et al [42] found that high usability scores in health apps are associated with increased user satisfaction and adherence to health recommendations.

Additionally, the app incorporates traditional massage techniques that align with local practices, making it more acceptable and practical for Indonesian caregivers, thus enhancing its relevance and effectiveness [36]. Furthermore, the app's offline functionality addresses the challenge of limited internet access in rural areas, where nearly 80% of the population lacks reliable connectivity. This approach aligns with global health strategies advocating for digital tools to improve maternal and child health outcomes, especially in resource-constrained settings.

This study, while demonstrating promising outcomes, is not without limitations. One notable constraint is the relatively small sample size, which may restrict the generalizability of the findings. Additionally, the research was conducted within a specific cultural and regional context in Indonesia, potentially limiting its applicability to other settings with different cultural norms and health care environments. To address these limitations, future studies should aim to include larger and more diverse participant groups, as well as evaluate the app's usability and effectiveness across varied cultural contexts. Another limitation is the short duration of the intervention, which prevents conclusions about the long-term impact of the app on infant growth and development. Extending the study period and incorporating follow-up assessments would provide deeper insights into the sustained benefits of the app. Furthermore, while qualitative feedback offered valuable perspectives on UXs, a more structured and comprehensive qualitative analysis could uncover additional insights into caregiver preferences and areas for improvement.

This pilot study used a single-arm pre-post design without a control group; therefore, causal inference cannot be established. Improvements in infant growth may have been influenced by natural growth progression or other unmeasured factors. Future randomized controlled trials are needed to confirm effectiveness.

Conclusions

This study highlights the effectiveness of a culturally tailored, human-centered baby massage mobile app in improving caregiver knowledge, confidence, and adherence to infant massage practices, while also positively influencing the growth and development of LBW infants in Indonesia. The app's high usability reflects its user-friendly design and intuitive navigation. The integration of such digital health tools into routine postnatal care offers a promising strategy for addressing the challenges faced by caregivers of LBW infants, particularly in low-resource settings. The app's culturally relevant content, local language support, and offline functionality make it accessible and practical for users in diverse contexts, including rural areas with limited internet access. Positive feedback from participants further emphasizes the app's value, with caregivers appreciating features such as step-by-step tutorials, progress tracking, and reminders. While minor usability concerns, such as the need for a more visually engaging interface, were noted, overall satisfaction with the app was high, indicating its potential as a reliable tool for supporting infant care. Looking ahead, future research should focus on scaling up the app, conducting longer-term evaluations to assess its sustained impact, and exploring its integration into existing neonatal care programs.

Abstract

Background: Parents' feeding practices play a role in shaping children's dietary patterns, which influence chronic disease risk. Feeding children is challenging, so parents need guidance and support. Parents In Child Nutrition Informing Community (PICNIC) is an Australian program that promotes responsive child feeding using dietitian-led training and online communication, then facilitates peer-to-peer information sharing within parents' social networks.

Objective: This pilot study aimed to test the feasibility, acceptability, appropriateness, and perceived impact of PICNIC with Swedish parents.

Methods: This explanatory sequential mixed methods study involved 47 parents of children aged 0 to 24 months. Parents attended a 2-hour online dietitian-led workshop, followed by 2 months of child nutrition and feeding support in a moderated, closed Facebook group. Quantitative data from digital questionnaires (n=43) were analyzed and integrated with qualitative findings from thematic analysis of semistructured interviews (n=15).

Results: Parents attended 1 of 10 workshops, and 4 to 5 posts per week (of which 20% were participants' questions) were shared in the project's Facebook group. Both quantitative and qualitative data indicated parents' child feeding knowledge and parental self-efficacy increased after participation. Parents reported that the intervention filled a gap in the existing support from child health services, strengthening their confidence in child feeding, while providing a sense of recognition and community. PICNIC information was described as trustworthy, shareable, and something to "lean on." Parents valued the social interaction during the workshops but also suggested providing recorded content for easier access.

Conclusions: This pilot study demonstrated high acceptability and appropriateness of the PICNIC intervention model among parents in Sweden. This study will inform the design of an adapted version of PICNIC to be offered through child health services.

Introduction

Background

Promotion of healthy lifestyle habits in early childhood is of paramount importance [1], as eating behaviors and dietary patterns develop early in life [2] and often persist into adulthood [3]. Children's eating behaviors are influenced by their parents' food habits and feeding strategies [4,5]. Responsive feeding is an evidence-based approach in which parents recognize and respond appropriately to children's hunger and satiety cues, while also modeling healthy eating behaviors [6]. It emphasizes repeated, neutral (nonpressured) exposure to a variety of foods,

XSL•FO
RenderX

which has been shown to shape children's preferences [7], such as increasing fruit and vegetable consumption [8].

Parents often describe child feeding issues as stressful and can find it difficult to translate available information into practice [9,10]. Qualitative research has shown that parents' child feeding practices are influenced more by peers (family and friends) than by dietary guidelines [10]. In addition, parents increasingly seek information and encounter advertising on social media and the internet, and may therefore be exposed to a confusing array of misinformation and conflicting advice as they strive to feed their children optimally [9]. Normal child eating behaviors, such as neophobia or "fussy or picky eating", also create concerns for parents [11,12] and can lead to nonresponsive parenting strategies such as pressure to eat or offering only accepted "safe foods," possibly impacting negatively on children's food preferences and development [13,14]. Higher perceived parenting competence, such as self-efficacy and satisfaction, has been reported to be positively associated with greater use of responsive food parenting practices [15].

In Sweden, the child health services (CHS) are responsible for offering parenting and child feeding support, aiming to empower parents through conversations during regular health visits and parent group sessions at the CHS center [16]. This health promotion work is particularly important, considering that less than 1 in 10 children and adolescents in Sweden meet the recommended fruit and vegetable intake [17,18] and approximately 10% of children have developed overweight by 4 years of age [19]. However, the national CHS program is multifaceted, leaving limited time for individualized, nutrition-related discussions [20]. CHS nurses frequently identify time constraints as a barrier to addressing family lifestyle habits, and these are complex topics that can be perceived as both sensitive and challenging to talk about [21,22]. Thus, there is a need for evidence-based resources to facilitate the support.

The "Parents In Child Nutrition Informing Community" (PICNIC) program is an ongoing population-level nutrition intervention in the Mid North Coast Local Health District, Australia, aimed at improving parental feeding practices and children's dietary quality [23]. PICNIC parents are trained in dietitian-led workshops and provided with ongoing, evidence-based plain-language child feeding information through online resources (website, Facebook, and Instagram; Meta Platforms, Inc). This peer education model was informed by formative research, which recommended early recruitment (<6 mo) and easy access to shareable online child feeding information to facilitate knowledge exchange and peer support between parents [10,24,25]. Parents co-designed the intervention, actively shared information with peers, contributed their experiences, and provided feedback to the research team through participatory action research [26]. Parents accessing PICNIC have shown improvement in child feeding practices and higher intake of vegetables in children compared to age-matched population data (Ball et al, manuscript submitted), and content analysis indicates that parents engage most with instructive ("how-to") content and messages on food restriction and fussy eating [27]. The online shareable format has shown potential to reach more than those directly engaged in the program [28]. For example, while a total of 1250 parents have been trained in a PICNIC workshop to date, PICNIC social media content reached almost 17,000 unique users on Facebook over the last month (as of January 2026; insights from Meta Business Suite).

The PICNIC project has attracted great interest from child and family health centers and is currently being scaled to other Australian health districts and new settings. This peer-to-peer education model may also be a suitable strategy to influence parents' feeding practices in Swedish CHS where no comparable programs currently exist. A feasibility trial is warranted to evaluate PICNIC transferability to the Swedish context and ensure that the program is tailored to meet end users' needs and expectations.

Aim

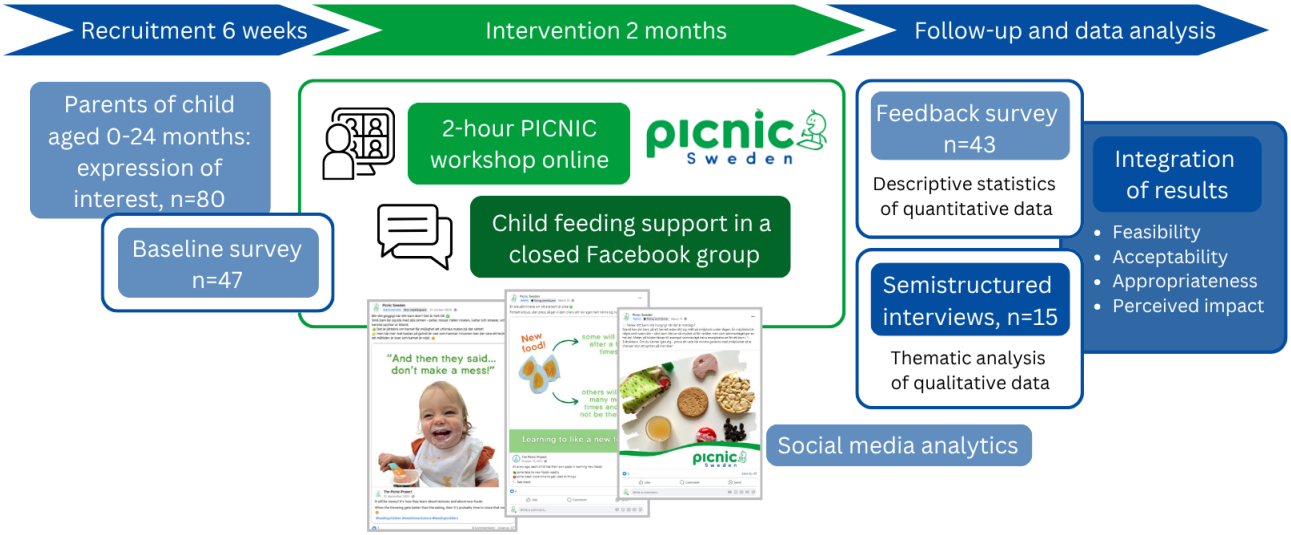
This pilot study aimed to assess the feasibility, acceptability, appropriateness, and perceived impact of the online peer education child feeding program PICNIC, developed in Australia, to be offered to parents of young children in Sweden.

Methods

Study Design

"PICNIC Sweden" was a mixed-methods single-group feasibility study designed to let parents in Sweden test an adapted version of the PICNIC child feeding peer education program, originally developed in Australia [23,26]. We used an explanatory sequential design integrating both quantitative and qualitative data to gain a comprehensive understanding of various feasibility aspects of the intervention in Sweden [29]. Data were collected concurrently between October 2023 and February 2024 and consisted of digital questionnaires, social media analytics, and semistructured interviews. This study is reported according to the COREQ (Consolidated Criteria for Reporting Qualitative Research) checklist (qualitative interviews) [30] and the guidelines for Good Reporting of A Mixed Methods Study (GRAMMS) [31] (Checklist 1).

Participants and Recruitment



Participants in this study were parents or primary caregivers of a child aged 0 to 24 months. To participate, parents had to be aged at least 18 years, reside in Sweden, and understand written and spoken Swedish sufficiently well to participate in the workshop and answer the surveys. Recruitment took place between October 1 and November 15, 2023, using convenience sampling in the health care region of Sörmland, combined with snowball (peer-to-peer) sampling. All 26 child health centers located in the region were sent recruitment material, including posters and brochures, for display and distribution within their centers and social media post templates for online CHS pages and groups. A link referred to the recruitment webpage at ki.se and the expression of interest form. Interested parents were emailed full study information and offered the option to receive further information via phone before consenting to participate in the study.

XSL•FO
RenderX

PICNIC Intervention

The intervention consisted of online training (a 2-hour virtual workshop on Zoom [Zoom Communications, Inc]) on food introduction and responsive feeding practices, as well as social network support resources (Figure 1). A registered dietitian (SA) with extensive experience working with families led the workshop, which was adapted from the Australian PICNIC project to a Swedish context. Thus, the same food introduction and responsive feeding concepts were covered, while the content was translated and adapted to Swedish dietary guidelines and the local food context. The only structural changes compared to the Australian original intervention included virtual workshops only (no face-to-face sessions) and no follow-up sessions, while the workshop duration remained unchanged (2 h). The participants were also invited to a closed Facebook group managed by the research team. In this forum, approximately 3 posts per week were shared to reinforce PICNIC messaging, either reshared from the Australian PICNIC page with Swedish captions or created by MHE and SA. The posts covered the same key concepts of responsive child feeding as those in the original Australian PICNIC and used a similar messaging tone. Parents could also submit child feeding questions through user-created posts, which were approved by the group administrator before being published and answered by the dietitian (SA) for the benefit of all group members. Group members could react ("like") and comment on all posts but could not share them outside the group due to Facebook privacy settings. As PICNIC used a peer education approach, participants were allowed to invite their partner, family, and parent friends to the Facebook group. However, entry required agreement to the group rules, which clearly outlined the group's purpose as part of a research project and explained that group-level engagement metrics would be collected. For this pilot study, no public resources were developed; only the closed Facebook group was used. Participants were, however, encouraged to visit the Australian PICNIC project website and social media pages (Facebook and Instagram) for additional resources.

Figure 1. Study design with flow of participants, data collection and analysis, and the "PICNIC Sweden" intervention with examples of Facebook content.

Data Collection

Questionnaires

A secure digital platform (REDCap, hosted at Karolinska Institutet) was used to distribute consent forms and digital questionnaires. A baseline questionnaire that included background parent or family and child characteristics and questions about previous experience of parent groups, perceived self-efficacy, and information-seeking behavior about healthy food and child feeding was distributed by email before participants attended the workshop. Two months after workshop participation, each of the 47 parents was approached via email and asked to fill in a follow-up questionnaire evaluating their program experience and providing feedback with regard to the research questions (feasibility, acceptability, appropriateness, and perceived impact). The questions were developed based on previous feasibility and intervention studies [24,32,33] and single items in validated questionnaires [34,35], modified to fit the current intervention, setting, and research aims. The questionnaires were pilot tested within the research team to ensure usability prior to data collection.

Social Media Analytics

Basic metrics, including the number of members as well as "active" engagement such as reactions or "likes" and comments, were exported from the Facebook group to Microsoft Excel by the administrator MHE. The data were then manually verified and supplemented with additional details, including post views (a type of "silent" engagement) by AJ after the study period. Only post reactions made by study participants were counted and included in the summary.

Semistructured Interviews

Semistructured individual interviews were conducted 2 to 3 months after the workshop (January to February 2024). The aim was to gain a deeper understanding of parents' views and experiences of the intervention, including perceived barriers to and facilitators of engaging in it, and potential impact. Using maximum variation sampling, 20 participants were invited in

XSL•FO
RenderX

the first round. The study sample was subdivided by education level, country of birth, gender, number of children, and age or gender of child for random selection by characteristic groupings. Nine parents consented to interviews (the reasons for nonparticipation were unknown). To reach the target of 15 interviews, which was considered adequate for acquiring rich and sufficiently detailed data, another 2 rounds of invitations were sent out to 6 and 3 additional participants, respectively, of whom 6 consented and completed an interview. Subsequent rounds on invitations were selected from those with the same combination of characteristics to increase the likelihood of capturing diverse perspectives and experiences. We intentionally sought to interview both mothers and fathers with varying educational levels and country of birth, as well as parents with one or multiple children, including both girls and boys across the age range represented in our study. Interviews were conducted via phone in Swedish by AJ, a female registered dietitian with clinical experience in counseling families with children and employed as a part-time research assistant in this project. The interviews were attended by AJ, the interviewee, and, in 2 cases, the interviewee's partner. The interviewees were aware that AJ was a research assistant, but no other prior relationship existed. The interview followed a semistructured format with a preset interview guide (Multimedia Appendix 1) developed by AJ and MHE (project leader, nutritionist, and assistant professor experienced in early intervention). The interview guide was pilot tested with a mother of a 6-month-old girl (not included in the study), resulting in minor revisions. All interviews were audio recorded and transcribed verbatim using a professional transcribing service, with final transcripts not reviewed by participants. Interviews lasted a mean of 41 (SD 8, range 28-60) minutes.

Data Analyses

Quantitative Analysis

The quantitative data in questionnaires as well as social media analytics were summarized with descriptive statistics using R (version 4.3.0; R Foundation for Statistical Computing) in RStudio (version 2023.3.0.386). A question on parental self-efficacy (PSE) for promoting healthy eating behaviors in their children, from the validated PSEPAD (Parental Self-Efficacy for Promoting Healthy Physical Activity and Dietary Behaviors in Children) instrument [35], was included in the questionnaires to enable comparison with previous studies and explore its distribution and change in this study population. The item response was a Likert-type scale, ranging from 0 (*not at all*) to 10 (*to a very high degree*). Although PSE change scores deviated from normality (Shapiro-Wilk test: W=0.90; P=.002), a 2-tailed paired t test was used as the primary analysis because of its robustness in samples of this size. A Wilcoxon signed-rank test was also conducted as a sensitivity analysis.

Qualitative Analysis

The 15 interview transcripts were analyzed using thematic analysis with an inductive approach [36,37]. First, data familiarization was performed through a read-through of all transcripts and initial discussions between AJ (registered dietitian), MHE, MH, and EBV, all female. Initial notes were taken to capture first impressions and emerging patterns in the data. MH and EBV were final-year bachelor's students in nutrition at the time, working on the data as part of their degree project. Supervised by MHE, systematic coding was performed independently by AJ and MH using meaning units and codes in Microsoft Excel 2023 (version 16.78.3). To achieve a shared understanding, the individual coding results and preliminary themes were discussed between AJ, MH, MHE, and KD in an iterative process. The themes were also refined by MHE through a revisiting of transcripts, coded data, and notes from the initial discussions. Final theme names and their scope were reviewed by all authors to reach consensus. The preliminary analysis was carried out in Swedish, with themes and quotations translated into English for co-analysis by English-speaking authors and for publication.

Data Integration

Quantitative and qualitative data in this sequential mixed methods study [29] were integrated using side-by-side comparison within framework analysis to interpret findings. Framework domains reflected the aims of understanding feasibility, acceptability, appropriateness, and perceived impact of the PICNIC program.

Ethical Considerations

All participants provided informed consent before participating in the study. To enter the closed Facebook group, members were required to accept the "group rules," which clearly described the purpose of the Facebook group and that group-level engagement metrics would be collected and reported in scientific communications. For the interviewees, additional informed consent was obtained after they had received individual invitations and study information related to the interview. No compensation was given to participants. The study was conducted in accordance with the Declaration of Helsinki, and the Swedish Ethical Review Authority approved this study (Dnr 2023-04381-01).

Results

Characteristics of Participating Parents at Baseline

Over a 6-week period, 80 parents submitted an expression of interest (Figure 1). Of these, 47 (59%) parents gave formal study consent, filled in the baseline questionnaire, and were able to attend 1 of the 10 workshops held during the trial period. Twenty (43%) participants resided in Sörmland, and 27 (57%) were from 6 other neighboring health care regions across central Sweden. They reported being recruited through their child health center or nurse (n=15, 32%), a social media post (n=8, 17%), or a friend or family member (n=24, 51%). Table 1 presents descriptive characteristics of the participating parents. The majority were mothers (46/47, 98%) born in Sweden (44/47, 94%) and aged approximately 33.8 (SD 4.8; range 22 - 44) years, and 43 (91%) participants had a university degree. Most participants had a child aged 6 to 12 months (22/47, 47%) or 0 to 6 months (17/47, 36%). While 25 (53%) parents had attended CHS parent groups, 20 (43%) reported not being invited to one at their child health center. The PSE was, on average, 7.8 (SD 1.5; range 5 - 10). Before engaging in the PICNIC intervention, more than half (27/47, 58%) of participants replied they *quite*

XSL•FO
RenderX

often or *very often* had questions on children's food or feeding, and one-third (14/47, 30%) felt they had not received sufficient child feeding support from CHS. The most common sources of information were the internet, the Swedish Food Agency website, family, friends, or other peers. The 15 interviewed parents were comparable to the study population in terms of demographic and baseline characteristics.

Process Evaluation and Social Media Engagement Metrics

Ten online workshops were held over a period of 5 weeks (October 10 to November 17, 2023), with an average of 4 to 5 participants per workshop, totaling 47 parents. An additional 3 fathers (not included in data collection) were present and listened in together with their participating partner. After the workshops, the closed Facebook group had grown to 60 members, including PICNIC team members or administrators, study participants, and peer-invited partners or friends. During the 4 months of Facebook group activities (October to January), a total of 52 intervention posts (including 9 video posts) were shared by the PICNIC Sweden team, and 17 user-created posts from parents were published and answered in the group. Regarding feeding-related messages, posts focused on children's learning to eat process (n=10), division of responsibility, including pressure to eat and feeding cues (n=9), meal environment and role modeling (n=8), what or how to serve (n=8), fussy eating (n=7), food exposure (n=6), and other or mixed topics (n=4). Most videos (5/9) addressed learning to eat. Notably, many posts were multimessaged, reflecting the intertwined nature of responsive child feeding practices. A variety of communication techniques were used, such as "how-to" content, storytelling, rhetorical questions, relatable and realistic photos and videos, and real-world tie-ins (eg, Christmas or Easter food) [27]. In general, the active engagement in the group was low; posts received an average of 2 "likes" (minimum to maximum: 0 - 7) from parents participating in the project. User-created posts always received some comments (3 on average, including the PICNIC dietitians' answers to questions), whereas 8 (15%) of 52 PICNIC-created posts received comments from parents. However, silent engagement, that is, viewing or reading posts, was overall higher, and while PICNIC-shared posts received 39 views on average, user-created posts received 47 views, suggesting higher "silent" engagement from parents with these question-and-answer type of posts. The most viewed PICNIC Facebook content (>55 views) included posts on what foods to serve, when and how to serve water, family meals (eating together), and the concept of "parents provide, children decide." The most engaging user-created post (58 views, 10 comments) was a parent's question on the use of taste buttons to introduce babies to new flavors.

Quantitative Survey Data—Follow-Up After PICNIC

Participants' responses to the follow-up questionnaire are presented in Table 2 (n=43, 91.5% response rate). Overall, the parents reported high satisfaction with the intervention and seemed to find the workshop especially useful. They also reported gained knowledge or insights, especially around how to practically manage different mealtime situations with their children. The mean PSE scores increased from 7.69 (SD 1.52) at baseline to 8.17 (SD 1.40) at follow-up among participants with data at both time points (n=42). A paired *t* test showed that PSE scores were significantly higher at follow-up than at baseline, with a mean increase of 0.48 points (95% CI 0.11-0.84; t_{41}=2.63; *P*=.01). A Wilcoxon signed-rank test yielded the same conclusion (*V*=601.5; *P*=.02). Furthermore, Facebook and Instagram were considered appropriate platforms for PICNIC, where open-ended answers (16/43, 37% chose to add a comment) explained that these were the most used platforms in this group today and the group function that Facebook provides was suitable for sharing in PICNIC; however, considering younger generations are not using Facebook as much, other platforms should be considered. Moreover, online engagement varied; while one-third (14/43, 33%) had actively viewed group posts 2 to 3 times per week and another third (15/43, 35%) more often than that, the remaining 32% (14/43) had viewed posts only once a week or more seldom (Table 2). Parents had shared information or advice from PICNIC primarily with the child's other parent (33/43, 77%), friends (25/43, 58%), and/or family (24/43, 56%), and most (30/43, 70%) considered it appropriate to be invited to PICNIC when the child was 3 to 4 months of age. Parents' opinions on the preferred format of the PICNIC workshop varied; most favored the online workshop as it was (41/43, 95%), but in-person meetings (14/43, 33%) and prerecorded information (17/43, 40%) were also suggested. Open answers to this question (28/43, 65% chose to comment) identified both pros and cons with different modes of delivery. Live workshops were considered valuable as questions could be asked directly to the dietitian. Parents commented that in-person meetings could be more socially enjoyable and boost discussions; however, getting there with the child may be challenging and time-consuming. Attending from home or from "anywhere" was considered more feasible. Prerecorded or self-directed options were commented upon as a good option for those who could not attend at a specific time or who wanted

to relisten but were suggested as a complement combined with interactive sessions or workshops to gain the benefits from both.

Qualitative Insights From Interviews

Thematic analysis of transcripts from the 15 interviews (descriptive characteristics in Table 1) resulted in 3 themes. These are presented in Figure 2 and described below. Selected quotes have been labeled with an identifying number, *mother* or *father*, total number of children, as well as age of their youngest child when enrolling in the project.

XSL•FO
RenderX

Figure 2. Themes in data from semistructured interviews with PICNIC (Parents In Child Nutrition Informing Community) participants.

Theme 1: Confidence in How to Feed Children

The parents described the intervention as pedagogic and useful. They reported increased understanding of how children learn to eat and perceived the information and advice as easy to absorb and apply in practice. This feeding efficacy led to increased self-confidence and greater trust in their child's own ability during mealtimes. For instance, parents reported feeling less anxious about offering new foods and textures for their young children to explore:

> *Not to get stuck with purées and ready-made baby food jars, but rather to cut up pieces of something easy to grip and gnaw on—and well, to dare a bit more.* [Mother of one (6 mo), ID8]

It was evident during the interviews that parents had learned about responsive feeding; they spoke about the importance of creating curiosity and joy for food, being a role model, and maintaining a neutral expression toward the child's eating behaviors and amount eaten. Many parents had become more aware of their own behaviors at mealtimes, and they shared stories on how they had changed practices and approach at home, resulting in a more positive atmosphere at the table:

> *I don't run around tidying up in the kitchen while he's eating—instead, I sit with him.* [Mother of two (youngest 6 mo), ID11]

Most participants emphasized that questions and concerns tend to arise when solid food is introduced and would be the ideal time to invite parents to PICNIC. Participating parents who had just entered their "food journey" also described the workshop as particularly reassuring, giving them "a foundation to stand on":

> *We were just at the beginning of our food journey with our daughter, and there was a sense of reassurance when hearing about, well, how to think about it, what needs to be considered, and what to stress over and not to stress over. I thought that felt super comforting.* [Mother of one (7.5 mo), ID2]

Parents with previous feeding experience with older children also found the intervention useful. Some felt reassured knowing that their feeding approach aligned with current evidence, while others reported reflecting on their past practices and now adopted new feeding strategies when introducing food to their second child. This was described as motivated by encouragement rather than blame or judgment:

> *But then when this project came along and everything...well, suddenly things just made sense. And became easier, I would say. I'd say that the food journey now with our second child has started off much better—easier.* [Mother of two (youngest 5.5 mo), ID6]

Participants' increased confidence and self-efficacy were partly attributable to their perception of the PICNIC content as trustworthy. Parents felt comfortable sharing PICNIC content because the advice was evidence-based and delivered and moderated by dietitians and nutritionists. Most had shared the information with partners, friends, or extended family members, who generally responded with interest and curiosity. Some also felt more comfortable discussing child feeding with their own parents:

> *Then my mom said, "Can't you just feed him, isn't he too young to eat by himself?" That's when I could use this information and explain that it's evidence-based—there are benefits to letting him squeeze and feel the food, look at it, and learn to put it in his mouth.* [Mother of one (5.5 mo), ID3]

XSL•FO
RenderX

Access to child feeding and nutrition expertise was recognized and highly valued by participants and also saved them time and effort relative to trying to access credible information online:

> *It was really nice to be able to ask so many questions and have someone who is an expert answer them every time. I felt like there's nowhere else you get that opportunity in the same way...I can search for as much information as I want, but to ask specific questions...felt very luxurious and...good.* [Mother of one (7.5 mo), ID2]

At the same time, participants emphasized the importance of experts being relatable and nonjudgmental:

> *She really seems very competent and good at talking to...people in an understandable way.* [Mother of one (7 mo), ID12]

Overall, participation in PICNIC provided parents with the type of information and strategies they needed to transition toward responsive child feeding. This was evidenced by apparent, constructive change in the feeding dynamic with their child, and in parents' reported feelings of reassurance and confidence, which motivated further engagement with the PICNIC online community and sharing of PICNIC principles with peers.

Theme 2: A Communal "Safe Space"

Being able to witness other parents' questions was highly appreciated by the participants, both during the workshop and in the Facebook group. Parents described how they could recognize their own situation in others, which created a reassuring feeling and a sense of not being the only one feeling "a bit lost":

> *Sometimes there are things you haven't even thought about yourself that other people bring up. And things you feel so alone in and think you're the only one who has...those issues. But then you realize that others experience the same.* [Mother of two (youngest 5.5 mo), ID6]

Several parents reported that participating in the project and being part of the supportive online group supported a sense of community, where hearing from other parents helped counter feelings of loneliness in their parental role. Thus, PICNIC filled a gap, particularly for those who had not attended parent groups at their child health center:

> *At the child health centre I go to, there are no parent groups or anything. And food is a really big thing, especially in the beginning [of parenthood]. So, I have appreciated being able to get advice from other parents and, well, having the opportunity to engage in that way.* [Mother of one (3.5 mo), ID4]

Some parents suggested additional workshops, with content tailored to the child's age, including ages beyond 0 to 2 years, and with online parent groups organized accordingly. This was perceived as a way to enhance the relevance and engagement of the content, as it would be even easier for parents to relate to. However, one parent pointed out that it could also be beneficial for first-time parents to hear about the experiences of those with older children:

> *At the same time, I think it can be helpful for first-time parents to hear from those who have more than one child, because as a first-time parent, you're often more worried, cautious, and maybe a bit nervous about it.* [Mother of two (youngest 4 mo), ID10]

Integral to the sense of community was the closed Facebook group being seen as a "safe space" to share. Parents appreciated its nonjudgmental tone and felt that all questions were welcomed, making it easier to engage:

> *It's a very friendly tone. Even I, who don't usually ask or comment much, have done so. Just because I've felt that the environment has been very, well, pleasant.* [Mother of three (youngest twins 8 mo), ID5]

While some parents actively engaged with PICNIC content or posted questions in the Facebook group, others preferred to observe. Although they found the content interesting and useful, they tended to comment or "like" only sparingly. Parents explained that this reflected personal considerations of privacy and a concern about being publicly visible and potentially judged, both within the group and on social media more broadly:

> *It's like...when you ask a question or post something, it's as if you're stepping out onto a stage...and in a way, exposing yourself.* [Mother of one (7 mo), ID7]

Participants perceived that having attended the online workshop encouraged them to feel comfortable to share or comment on posts. Keeping the groups relatively small and local, as well as meeting each other in person, was believed to further enhance engagement:

> *I think it also gives a sense of security, like, "Okay, I know who's going to read this, I know them a little."* [Mother of one (16 mo), ID1]

Notably, while most content was consumed online, on-sharing was done primarily through word-of-mouth:

> *I haven't done it [shared content] on social media. But I've talked a lot about it.* [Mother of one (7.5 mo), ID2]

Overall, parents responded positively to the peer education model, explaining that one typically perceives information as more trustworthy when obtained from someone with personal experience and that you know. Some parents described how friends who became parents found food introduction overwhelming and feared making mistakes, and PICNIC was seen as an opportunity to share a reassuring resource that friends could rely on.

> *When mentioning this project, everyone has been really curious and kind of like, "We would've wanted this too." So I think many people...well, sometimes you don't realize you're missing something until you have it, and it's been a bit like that with PICNIC.* [Mother of two (youngest 5.5 mo), ID6]

Participants emphasized the importance of involving fathers, recognizing their significant role in child feeding. The predominance of mothers in parent groups at child health centers and in child feeding groups on social media was reflected upon.

XSL•FO
RenderX

Some participants attributed this to the common practice in Sweden of mothers staying home during the child's first year, leading to a greater involvement in feeding. Others suggested that differences in information-seeking behavior and peer support needs between men and women may play a role:

> *...men maybe don't talk to each other in the same way, like "Hey, I heard about this," as we women do.* [Mother of one (5.5 mo), ID3]

The effectiveness of the PICNIC peer model hinged around engendering a feeling of safety for participants. The combination of shared life stage (parenting) and exposure (PICNIC) meant participants were willing to share vulnerabilities, which then perpetuated deeper connection and a more meaningful experience. The model could require adaptation to be as effective for men and for different cultural groups.

Theme 3: Access and Enhancement

The theme of access and enhancement related to the suitability of accessing the PICNIC content for participants and other parents. They reflected on and compared their experience of accessing PICNIC content with previous experiences and considered other parents who may have more challenges accessing and engaging with PICNIC.

The live, online format was considered convenient, as parents enjoyed the social interaction while also easily participating from their home environment, with the capability to "mute themselves" when needing to care for their children. However, it was also posed that in-person workshops would be more "fun," with the child health center suggested as a venue. Physical meetings were thought to boost discussions among parents and may also help increase engagement in the online Facebook group afterward:

> *Of course, it helps if you can do it digitally,...you open the door for more people to participate. At the same time, I do feel that when you meet in person, it's a bit easier to really be present in the moment and take in all the information. So there's a bit of ambivalence in my answer, but in any case, some form of real-time workshop.* [Mother of one (6 mo), ID8]

Recorded workshops or material were also discussed, and several parents highlighted the benefits of this approach, such as the ability to view it anytime, pause, and relisten, and to share it with their partner. Some also acknowledged the efficiency and potential for wider reach compared to live meetings. On the other hand, it would limit social interaction and viewing material may not be prioritized when it is not scheduled:

> *If it's a lecture you can watch anytime, it's easy to say, "Yeah, we don't have time tonight, we'll do it tomorrow," and then forget about it.* [Mother of one (7 mo), ID7]

Overall, parents identified both advantages and disadvantages of different workshop delivery modalities, primarily related to ease of access. Some suggested having a range of options to accommodate differing needs, while others suggested a hybrid format. Parents also emphasized that the quality of a workshop largely depends on who leads it, regardless of the delivery method.

The accessibility of simple Facebook posts that reinforced workshop content was appreciated. Posts appeared in parents' feeds and functioned as friendly reminders reinforcing PICNIC feeding messages. To boost engagement, creative content ideas and the combined use of multiple social media platforms were proposed:

> *To have it appear in your daily scrolling, and then very simple things like "Think about this" or "Good things to know" or something. I think it's a format that's incredibly helpful, and especially for parents with small children, it can be so easily accessible.* [Mother of one (7.5 mo), ID2]

As a hosting platform, Facebook was perceived by most parents as accessible and appropriate because of its closed group format with moderated content. However, some parents noted that Facebook use is lower among younger parents and therefore suggested other options be explored. Some also emphasized that because not everyone uses social media, emails with the same content should be included as a complementary feature.

Interviewees felt PICNIC's focus on *how* to feed children was relevant across diverse cultures and family situations, and integrating it into standard CHS care was seen as a way to enhance credibility and accessibility. However, reaching and engaging different parents could be a challenge, and adaptations would be needed. Suggestions included translating and culturally adapting content for non-Swedish-speaking parents, and addressing other potential barriers such as low education, intellectual disabilities, and limited social media use:

> *I think the content itself...it's not too difficult for someone with only an upper secondary education, I think, or with a different cultural background. But the question is how you reach people.* [Mother of two (youngest 6 mo), ID11]

To improve comprehension and engagement, alternative communication channels and tailored content, such as topic-specific workshops or question-and-answer sessions, were proposed. Parents expressed a desire for more practical meal tips, and one asked specifically for advice for a child with multiple allergies, noting limited guidance from CHS:

> *Our son is allergic to pretty much everything—milk, eggs, nuts...and it's really hard to find information and recipes and such, food-wise.* [Mother of one (12 mo), ID9]

One mother described herself as the "food encyclopedia" at home and said she would have appreciated it if her partner had received the information directly. However, while many wished fathers would be more engaged in learning about responsive child feeding, they also recognized that it may be challenging to reach them with an intervention like PICNIC. They emphasized that the intervention probably needs to be "dad focused," with information tailored specifically to fathers and their role. Some suggested more active recruitment through CHS but also at places where fathers tend to meet during parental leave:

XSL•FO
RenderX

> *Maybe information from CHS—even if the mother goes [to CHS visits], she can bring the information home to the father—or open preschools [a free drop-in centre for parents and young children], where more fathers might be when children are a bit older...* [Mother of one (12 mo), ID9]

A father who participated in the project highlighted the underrepresentation of fathers in such interventions and also suggested open preschools could be a way to engage them. During his parental leave, when his daughter was aged 10 to 18 months, he felt strongly responsible for her eating. However, he reported a lack of guidance and that other fathers would sometimes choose convenient "safe" options to avoid making mistakes:

> *I've also noticed with other dads, yeah, it's not so easy to find information...and if you want to be sure, you just grab a baby food pouch—then it can't go wrong. Or things like that.* [Father of one (21 mo), ID13]

Accessibility of accurate, relatable information, facilitators, and peer support was considered a key success factor in this pilot intervention. To enhance access, parents suggested using hybrid (in-person and online) delivery options or simulating characteristics of in-person participation as much as possible in the online environment. To effectively facilitate on-sharing of PICNIC content, social media platforms need to have suitable functionality and popularity with participants and prospective participant cohorts.

Synthesized Data

In Table 3, key results from the quantitative and qualitative data are compared side-by-side based on framework domains reflected by the aims of the study: to understand feasibility, acceptability, appropriateness, and perceived impact of the PICNIC program.

XSL•FO
RenderX

Table . Quantitative and qualitative data integrated and compared based on the sequential mixed method study aims.

Domain	Quantitative	Qualitative	For further exploration
Feasibility (logistics)	• Use of online and social media communications • High workshop interest, enrollment, and participation • High retention to follow-up • Social media content feasible	• All aspects highly feasible for mothers • Peer education model feasible with PICNIC[a] structure and format (workshop, closed social media group, and supporting resources)	• PICNIC peer-to-peer education and support model would benefit from further exploration • PICNIC scope requires clear boundaries explained (behavioral focus, can triage but not treat sensory and complex child feeding issues) • Scalability of face-to-face model may limit feasibility
Acceptability (subjective, a good social fit)	• High acceptability for parents of first child or with more than one child • Relatively high "silent" engagement in the closed Facebook group, with a higher number of post views in user-created posts (47 views per post) than PICNIC social media posts (38 views per post) • 93% would have continued in Facebook group • 77% had shared with partner • >50% had shared with friend or family • Content easy to absorb and apply in practice	• Highly acceptable to mothers, potentially acceptable to fathers, with modification • Facebook group and website highly acceptable alternative to current information-seeking approaches • Sense of solidarity and community • Nonjudgmental tone supported engagement • Social media platform acceptable to active sharers and observers, especially with known contributors (other PICNIC parents) and expert moderators • Acceptability of PICNIC participation, engagement for fathers and culturally diverse groups requires further exploration • Facilitator's approach and demeanor valued	• To optimize social media closed group engagement and access, parents need to feel secure (in platform and group) • Adaptations needed to be feasible for culturally diverse groups • Need for "dad focused" arm of PICNIC—they may have different ways of consuming and engaging with content and different mindsets about feeding
Appropriateness (suitable, fit for context, objective)	• Complemented or supplemented child feeding support from child health services • Appropriate to promote peer and family sharing of child feeding information or content • 3 - 4 months most appropriate child age for parent to commence PICNIC	• Expertise of facilitator • Application of responsive feeding practices • Invitation to PICNIC around the time of introducing infant to solid food considered most appropriate • Responsive feeding principles appropriate across cultural and gender contexts, but different approaches needed to reach different target groups	• Consider separate groups for first-time parents and those with more than one child (or shared groups for peer learning)? • Adaptations needed to be appropriate for fathers and culturally diverse groups
Perceived impact (outcomes, what happened as a result of involvement)	• Significant increase in parental self-efficacy score from baseline to follow-up • Self-reported increased practical skills for managing mealtimes	• Increased feeding efficacy reported • "Safe space" to share decreased stress and burden of child feeding • Information from someone with lived experience perceived as trustworthy and impactful	• Further research should measure child feeding, child diet quality, parental efficacy, and parenting-related anxiety outcomes over more than 12 months

[a]PICNIC: Parents In Child Nutrition Informing Community.

Discussion

Principal Findings

This study confirmed that the PICNIC program is feasible, acceptable, and appropriate and has potential for high impact in Sweden. Overall, parents participating in this pilot study reported improved confidence in their parental role regarding child feeding from participating in the project, and PSE also improved significantly from baseline to follow-up. In interviews, parents described how the advice shared in PICNIC had made

XSL•FO
RenderX

a difference in their family meal situations. This, together with the evidence-based content and inclusive facilitation, encouraged parents to want to share the information with others. The focus on responsive feeding was considered applicable for "everyone." Interviewed parents also identified the need and opportunities to improve reach to specific, underserved groups of parents and ways to optimize PICNIC program delivery. The intervention filled a gap complementing the support received from CHS and providing a sense of community and opportunity to share and recognize oneself in others.

Comparison With Prior Work

This mixed methods pilot study indicated that the PICNIC program format is feasible and scalable, with adaptations needed for it to be acceptable and appropriate for fathers and culturally diverse groups. Consistent with qualitative analysis of the culturally adapted Healthy Beginnings program, feasibility and acceptability for culturally diverse groups depend on the availability of in-language resources and access to bicultural health professionals or support workers [38]. Language barriers between parents and health professionals can pose communication challenges [39], and Swedish CHS nurses have described a need for more cultural competence training and knowledge [40]. In the digital space, learnings from cultural adaptations of the MINISTOP mobile app in Sweden also showed that translation alone is not sufficient; literacy needs must also be addressed, for instance by providing video or audio formats [41].

Although this pilot study was not powered to assess intervention effectiveness, we observed a statistically significant improvement in PSE from baseline to follow-up. Both the baseline PSE level (mean 7.7, SD 1.5, among 42 complete cases) and the observed increase (0.48 points on a 0 - 10 scale) were comparable to findings from the Swedish MINISTOP 2.0 trial, which used the same PSE item [32]. These findings suggest that the PSE item showed sufficient variability in our target population, with no indication of a ceiling effect, and was sensitive to change. This warrants further investigation in a well-powered interventional randomized controlled trial using validated PSE instrument(s).

The principles of responsive feeding form the basis of the PICNIC program and were considered feasible, acceptable, appropriate, and impactful in this pilot study. Participants expressed that responsive feeding is powerful and applicable across child ages and stages and across diverse cultural and gender contexts [6,42]. Although fathers' feeding practices have been reported as modifiable when their partner participates in a child feeding intervention [43], direct involvement is likely to enhance engagement and peer sharing with other fathers. However, different approaches were considered necessary to reach fathers and other underserved groups, and examples of responsive feeding practices may need adaptation to pique interest and identification with the concepts [42]. For example, fathers may have a need for more organizational and practical support [44] or may engage more if they understand how influential their feeding practices are on their child's health outcomes [45]. Individual peer-to-peer support from a "father mentor" trained in the PICNIC model could also be explored as an approach to specifically engage and support fathers. Similarly, concepts such as food security may resonate with parents from different cultural contexts [6].

The PICNIC program requires a highly developed and specific facilitation skill set, including expertise in both responsive feeding and the ability to apply the principles to meet the needs of a wide range of prospective participants. It was clear in this pilot study that this needs to be balanced with an empathic and approachable facilitation style. This finding is consistent with previous research, with a systematic review highlighting the importance of practitioners being nonjudgmental [46].

This pilot study showed that parents engage with PICNIC to meet their own needs in feeding children and that their altruistic intentions to support and educate other parents evolve as their own confidence grows and they want to share their learnings and experiences. This phenomenon mirrors the qualitative findings from PICNIC implementation in Australia, with delineation between peer educators' and education recipients' roles considered unrealistic because a high proportion of peer education recipients subsequently became peer educators. As a result, the "educator" role was therefore reframed toward a "champion" model, in which all parents exposed to the PICNIC intervention became "PICNIC parents" [26]. The impact of peer-to-peer support on recipients' child feeding, along with the concept of a dual parent-peer role and the value of peer education versus peer support, requires further exploration in a larger trial.

To be sustainable and impactful, the PICNIC peer education model needs clear boundaries and referral pathways. The initial workshop provides an opportunity to discuss scenarios where PICNIC content is adequate and what to do if parents inquire about topics that are out of scope for parent-to-parent peer support, for example, sensory and complex child feeding issues. For enduring feasibility, PICNIC needs to optimize reach without overstretching resources, be clear about scope, and ensure facilitators are well trained with a combination of expertise and empathy, and that social media content and the website or other online information platforms are maintained.

The acceptability and appropriateness of the PICNIC pilot program were evidenced by high interest and uptake, high engagement, and enthusiastic quantitative and qualitative feedback. The format of involving an educational workshop to "meet and greet" and be "on the same page," followed by ongoing incremental "drip feeding" of content, served a dual purpose. This format is also consistent with the educational concept of balancing reinforcement and extension of learning, without information overload or message fatigue [47]. In parallel, familiarity and trust were built between participants and with the facilitator, which served to create the "safe space" for sharing. Meanwhile, participants in the present study identified pros and cons with in-person versus online and suggested recorded or self-directed learning in addition to interactive live sessions. Thus, alternative modes of delivery should be explored when PICNIC is further adapted for the Swedish context to optimize reach to a diverse group of parents while using resources effectively.

XSL•FO
RenderX

It was notable that participants felt more comfortable sharing in person or with close peers, whereas sharing through liking or on-sharing social media posts was less common. This reluctance among some parents to like and share content may reflect their insecurity about feeling vulnerable in their parenting role in a wider, less familiar forum or a limited awareness that liking and sharing could be a way to on-share the information that resonated with them. Previous research has shown that "nonclickers" on social media can still be active content viewers and that personality and perceived attitudes toward clicking and on-sharing can influence decisions to do so [48]. Finding a balance between broader peer sharing while maintaining the sense of a "safe space" is a challenge for the PICNIC program as it expands to more parent groups [49].

Anticipatory guidance is a strategy used effectively in the original Australian PICNIC program to match content to the learning needs of participants. As children's eating behaviors evolve rapidly with their stage of development, anticipating what they will likely experience in the next stage is both a science and an art [50]. The age of the children was described as a key factor for how well the parents related to the content in PICNIC, with early intervention around the time of introducing solids considered ideal. Relatable content that they could recognize themselves in was most valued, and some parents therefore suggested making the intervention more age specific. This suggestion was counterbalanced by feedback highlighting the value of input from parents who had more than one child or had already experienced situations relevant to a child transitioning through that particular stage. To increase the acceptability and appropriateness of content across child ages and stages, while remaining logistically feasible, PICNIC programming needs to consider and incorporate these concepts and expectations into planning, implementation, and continuous evaluation.

Strengths and Limitations

The strengths of this study included the mixed methods approach in which qualitative data corroborated and contextualized the quantitative results. Maximum variation sampling was used for the interviews to capture a broad range of participant perspectives and experiences, where 15 interviews were considered sufficient for ensuring data richness and saturation. The trustworthiness of the study was also strengthened by investigator triangulation, in which 2 investigators at different professional levels independently coded the qualitative data. The other coauthors then discussed and provided feedback on the results in an iterative process, revisiting the original data when needed. As this was a pilot study, baseline recruitment continued until at least 40 participants had enrolled and were scheduled for 1 of the 10 PICNIC workshops offered. This was considered adequate and feasible for the nature of the study, but not large enough to measure objective outcomes. Nevertheless, despite the small sample size, we observed a statistically significant improvement in PSE from baseline to follow-up. We did not quantitatively measure intervention effectiveness, such as parents' child feeding practices or children's eating behaviors; this should be investigated further in a well-powered randomized controlled trial.

Furthermore, most parents who participated in this study were female and highly educated. This pattern is commonly seen in this field of research and is a limitation that may influence the transferability of findings to other parent groups. However, it also indicates which parents are most likely to engage voluntarily in PICNIC, suggesting that others may require more active outreach. At the same time, it was surprising that as many as 43% (20/47) of our study participants had not been invited to a parent support group at their child health center. Such groups should be offered as universal CHS support [16], but national statistics from 2023 to 2025 show that only 20% to 30% of children have parents attending [51]. This indicates that further efforts are needed to expand group health care in Sweden and address barriers to parent participation. Previous qualitative research shows that mothers often feel isolated during the first year of parenthood and express a need to share their experiences and to feel supported, reassured, and understood [44]. Parents who cannot attend physical CHS group meetings may therefore benefit from PICNIC's online peer support. Meanwhile, Swedish CHS follows the principle of proportionate universalism, aiming to provide equitable care by offering targeted support to families with greater needs. This should guide prioritization of target groups, especially if resources are limited.

Conclusions

This pilot study indicated that Swedish parents of young children found the PICNIC peer education model feasible, acceptable, and appropriate for supporting parents in responsive child feeding. Engaging with the intervention resulted in parents feeling more confident in their parental role and in the child feeding process. Recognizing their own experiences in other parents' questions within a nonjudgmental "safe space" felt reassuring. The parents highly valued the direct access to expert advice and opportunities to interact with other parents, while also seeing value in recorded content. A large-scale effectiveness-implementation trial will evaluate whether "PICNIC Sweden" can improve feeding practices and children's eating behaviors. The planned study will also determine how the program can be realistically scaled within available resources, CHS settings, and conditions.

Acknowledgments

The authors thank Jessica Miregård, coordinating dietitian in Region Sörmland. The authors also thank the Australian PICNIC (Parents In Child Nutrition Informing Community) team at the Mid North Coast Local Health District and the University of Newcastle, New South Wales, Australia, including coauthors KD and RB, and health promotion dietitian Rachel Gerathy, for their continuous support, for creating the "PICNIC Sweden" logo, and for providing us with access to original PICNIC social media content/resources. The authors also want to thank all the parents participating in this study. During the preparation of this

XSL•FO
RenderX

manuscript, Microsoft Copilot was used to improve clarity and grammar. All content was reviewed and edited by the authors, who take full responsibility for the final version.

Funding

The study was funded by a project grant from Henning and Johan Throne-Holst foundation to MHE (2023-05-15). The funder had no involvement in the study design, data collection, analysis, interpretation, or the writing of the manuscript.

Data Availability

The interview transcripts generated and analyzed in this study are not openly available to maintain participant confidentiality. However, supporting information such as analysis documentation is available from the corresponding author upon reasonable request.

Authors' Contributions

MHE, KD, RB, and SA conceptualized the pilot study, and MHE acquired the funding; MHE and AJ collected the data and delivered the intervention together with SA; AJ and MH coded the qualitative data, followed by thematic analysis supervised by MHE; MHE, EBV, and AJ summarized the quantitative data; data were merged by KD and MHE, who led the manuscript writing with contributions from AJ. All authors critically reviewed the manuscript and approved the final version. While MHE is principal investigator for "PICNIC Sweden," RB is principal investigator, and KD is co-investigator of the original PICNIC program running in Australia, on which the intervention in this study is based.

Conflicts of Interest

None of the authors have a conflict of interest. Coauthor SA, a registered dietitian, who previously worked clinically, is currently self-employed as a writer and educator on the topic of nutrition.

Abstract

Background: The Asia-Pacific region faces an escalating double burden of malnutrition, with childhood obesity now affecting more than 113 million children aged 0 - 19 years. A demographic of highly educated, digitally literate urban mothers—referred to in this study using the descriptive label “Alpha Mother”—increasingly draws on generative AI as a source of toddler nutrition information. Yet, whether this shift empowers or undermines quality feeding practices remains empirically untested.

Objective: This study examined how generative artificial intelligence (AI) engagement is associated with perceived nutrition-oriented feeding practices among urban Alpha Mothers in Indonesia, with cognitive empowerment and parental self-compassion as intervening variables, and eHealth self-efficacy as a moderator. The study contextually refined 5 AI engagement dimensions, organized through an AI parenting nutrition alignment approach.

Methods: An exploratory sequential mixed methods design was used. Phase 1 comprised semistructured interviews with 10 Alpha Mothers and used hybrid deductive-inductive thematic analysis to contextually refine 5 literature-informed AI engagement constructs: AI algorithmic trust, AI health information quality, AI personalization fit perception, AI information-seeking intensity, and AI social proof sensitivity. These informed a survey instrument developed through the qualitative phase and refined against previously validated scales in phase 2, recruiting 442 respondents across 4 Indonesian urban centers. A 14-hypothesis structural model was tested using PLS-SEM (partial least squares–structural equation modeling)

Results: Twelve of 14 hypotheses were supported. The model demonstrated substantial explanatory power for cognitive empowerment (R^2=0.661) and parental self-compassion (R^2=0.719), while perceived nutrition-oriented feeding practices yielded a more modest value (R^2=0.280). This result reflects the multifactorial nature of self-reported nutrition-oriented feeding practices, which is shaped by numerous personal, cultural, and situational factors beyond AI engagement. AI algorithmic trust showed the strongest association with parental self-compassion (β=.479; P<.001), while AI personalization fit perception most strongly predicted cognitive empowerment (β=.275; P<.001). Both intervening variables were significantly associated with nutrition-oriented feeding practices, with cognitive empowerment (β=.232; P=.003) outperforming parental self-compassion (β=.165; P=.009). eHealth self-efficacy moderated the cognitive empowerment pathway (β=.124; P=.02) but not the self-compassion pathway.

Conclusions: The findings suggest that generative AI engagement is associated with perceived nutrition-oriented feeding practices via 2 distinct indirect associations examined in this study: cognitive empowerment and parental self-compassion. These associations were strongest when mothers trusted the AI system and perceived its recommendations as fitting their child and household realities, indicating that the perceived value of AI in toddler feeding may lie less in algorithmic sophistication than in its capacity to build trust, fit context, and support maternal judgment. Because the outcome reflects maternal perception rather than observed feeding behavior or child nutrition outcomes, these findings should be interpreted as associational. They may nonetheless inform future research on AI-assisted feeding support that complements, rather than replaces, professional nutrition counseling.

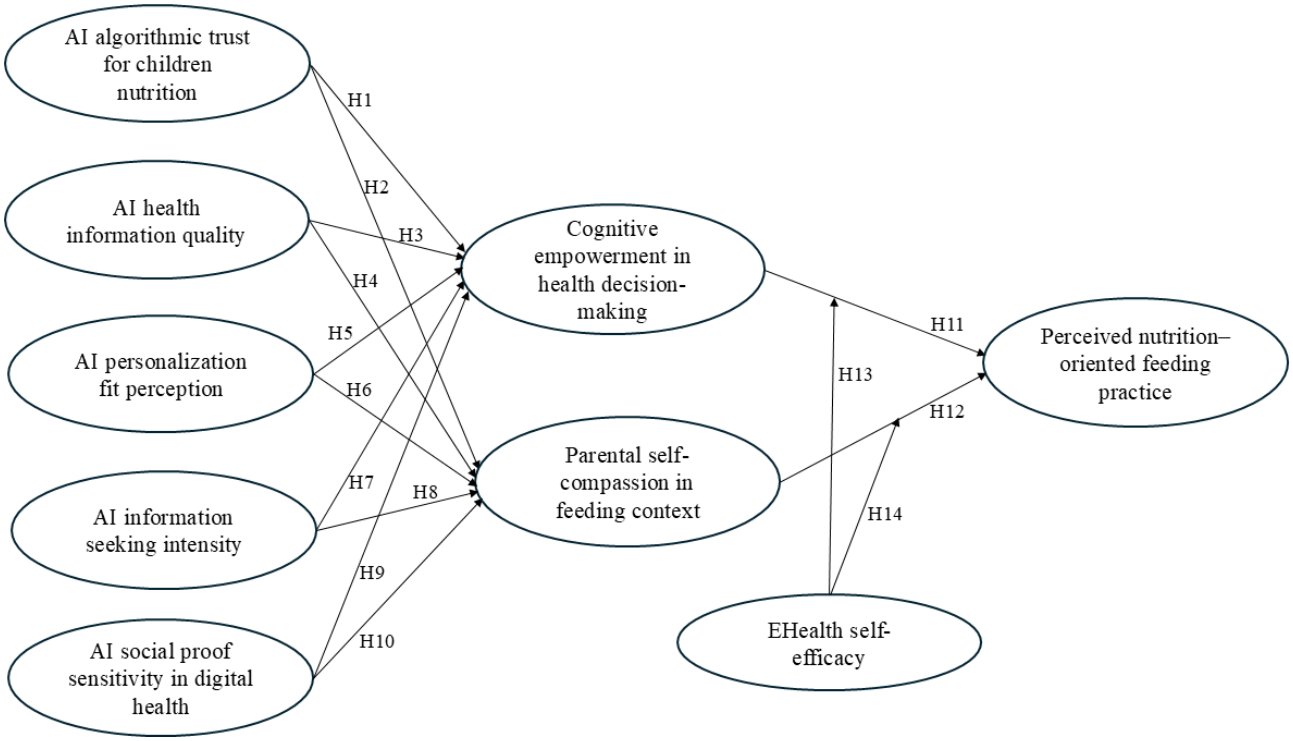
Introduction

Southeast Asia continues to face a double burden of malnutrition, with persistent undernutrition coexisting alongside rapidly increasing childhood overweight and obesity [1]. In East Asia and the Pacific, more than 113 million children aged 0 - 19 years are overweight or obese, with Indonesia among the countries substantially affected [2,3]. Early dietary patterns established during the toddler period play an important role in shaping lifelong eating behaviors and health outcomes, making caregiver feeding practices an important target for public health intervention [4]. The quality of these early feeding practices, rather than obesity as a measured outcome, is the focus of this study. Accordingly, the World Health Organization (WHO) and the United Nations Children's Fund (UNICEF) identify responsive feeding as a cornerstone of optimal infant and young child nutrition, emphasizing reciprocal caregiver-child interactions that encourage autonomous eating, healthy food preferences, and appropriate responses to hunger and satiety cues [5]. Consistent with this principle, the WHO Guideline for Complementary Feeding of Infants and Young Children aged 6 - 23 months recommends responsive feeding alongside continued breastfeeding, age-appropriate complementary feeding, dietary diversity, and limiting unhealthy foods and beverages [6]. These recommendations provide an important benchmark for evaluating how emerging digital technologies may support or potentially undermine maternal feeding decisions.

Despite these recommendations, maintaining responsive feeding has become increasingly challenging for many Indonesian mothers who simultaneously balance employment, caregiving responsibilities, and growing exposure to digital nutrition information and commercial food marketing [7-10]. Social media further amplifies conflicting dietary advice, increasing cognitive demands and making it more difficult to distinguish evidence-based recommendations from misinformation [11,12]. Contemporary motherhood literature describes an emerging demographic of highly educated urban mothers who combine professional identities with intensive parenting practices centered on optimizing children's development [13,14]. To characterize this population, this study adopts the descriptive label "Alpha Mother," a term previously used in motherhood literature to describe technologically engaged mothers who actively seek expert guidance for child-rearing decisions [15]. Related scholarship further suggests that online parenting environments reinforce intensive mothering ideals through social comparison and curated self-presentation [16,17]. In this study, the term refers specifically to urban Indonesian mothers with tertiary education, relative economic stability, and active use of generative artificial intelligence (AI) for toddler nutrition information. It is used solely as an analytical descriptor of the study population rather than as a normative ideal of motherhood.

As digital health technologies become increasingly integrated into parenting, Alpha Mothers are also adopting generative AI platforms as convenient sources of personalized nutrition information [18-24]. Unlike conventional search engines, conversational AI can provide interactive, context-sensitive responses that may help mothers navigate complex feeding decisions while managing substantial cognitive demands. However, these potential benefits remain accompanied by important limitations. AI-generated health information is highly dependent on user prompting and remains susceptible to hallucinations, inaccurate recommendations, and embedded biases [25-27]. Furthermore, although AI may complement evidence-based resources such as the WHO and UNICEF Community Infant and Young Child Feeding (C-IYCF) Counselling Package, its role in supporting maternal decision-making has not yet been sufficiently established.



Beyond information quality, the conversational nature of generative AI introduces additional psychological considerations. Human-like responses may encourage users to attribute credibility, empathy, and emotional understanding to AI systems despite their lack of genuine interpersonal awareness—a phenomenon referred to as pseudoempathy [28,29]. Such interactions may foster algorithmic authority, whereby users increasingly defer health-related decisions to algorithmic recommendations rather than their own judgment or professional advice [30-34]. While traditional maternal feeding research has largely relied on knowledge-attitude-practice frameworks [35], these models do not fully capture AI-mediated parenting decisions in which trust, cognitive burden, and perceived personalization influence how caregivers interpret health information [27,36-39]. Consequently, understanding maternal engagement with generative AI requires conceptual approaches that extend beyond conventional behavioral models.

Although digital motherhood, AI-assisted health communication, and parenting technologies have received increasing scholarly attention, little empirical research has examined how maternal engagement with generative AI relates specifically to perceived nutrition-oriented feeding practices within real-world parenting contexts. To address this gap, this study proposes the AI Parenting Nutrition Alignment Approach, a conceptual framework informed by prior literature and contextually refined through the qualitative phase of this mixed methods study. Drawing on Sánchez-Vera's [40] 3 dimensions of algorithmic agency—structural, operational, and symbolic—the approach describes how AI-generated nutrition advice aligns with mothers' child characteristics, cultural context, household circumstances, and parenting values. Rather than introducing entirely new behavioral theories, this framework organizes the 5 AI engagement dimensions refined through a hybrid deductive-inductive thematic analysis conducted during phase 1 into a coherent structure for subsequent quantitative evaluation. The study's primary contribution therefore lies not in proposing new theoretical constructs but in operationalizing these dimensions and demonstrating their convergence with established constructs within this specific parenting context.

XSL•FO
RenderX

Building upon the AI Parenting Nutrition Alignment Approach, this exploratory sequential mixed methods study investigates how generative AI engagement is associated with perceived nutrition-oriented feeding practices among urban Indonesian Alpha Mothers. Specifically, the study examines whether these relationships are indirectly associated via the complementary constructs of cognitive empowerment and parental self-compassion, while evaluating eHealth self-efficacy as a potential moderator. Guided by these objectives, 2 research questions were formulated. Research question 1: To what extent is generative AI engagement associated with the 2 intervening constructs—cognitive empowerment and parental self-compassion—and, in turn, with perceived nutrition-oriented feeding practices? Research question 2: Does eHealth self-efficacy serve as a boundary condition in the indirect associations involving these constructs to perceived nutrition-oriented feeding practices? To address these questions, 14 hypotheses were developed. The 5 AI engagement dimensions refined through the qualitative phase—AI algorithmic trust, AI health information quality, AI personalization fit perception, AI information-seeking intensity, and AI social proof sensitivity—were hypothesized to be positively associated with cognitive empowerment and parental self-compassion (hypothesis [H]1 to H10). Both intervening constructs were further hypothesized to be associated with perceived nutrition-oriented feeding practices (H11 to H12), while eHealth self-efficacy was hypothesized to moderate both construct–outcome relationships (H13 to H14). The resulting conceptual framework is presented in Figure 1.

Figure 1. Conceptual framework. AI: artificial intelligence.

Methods

Study Design

This study used a mixed methods exploratory sequential design [41]. The initial qualitative phase explored Alpha Mothers' interactions with AI to understand maternal emotional dynamics and to refine and contextualize key constructs. These findings directly informed the subsequent quantitative phase by guiding item development, refining definitions, and contextualizing scale wording to reflect actual feeding experiences. Finally, the second phase empirically tested the derived structural model and research hypotheses within a larger population sample. The resulting conceptual framework, which maps the 14 proposed hypotheses and structural pathways, is illustrated in Figure 1.

Mixed Methods Integration: From Qualitative Themes to Quantitative Constructs

Consistent with the exploratory sequential design, the 2 phases were connected at an explicit point of interface: the 5 literature-informed domains were contextually refined in phase 1, and the resulting subthemes and indicators informed the constructs measured in phase 2. Each of the 5 AI engagement dimensions—algorithmic trust, health information quality, personalization fit perception, information-seeking intensity, and social proof sensitivity—was operationalized into a measurable construct with a corresponding conceptual definition and a dedicated set of survey items.

The quantitative instrument was developed in several stages. Items were developed from the context-specific subthemes and indicators identified in phase 1 and refined with reference to previously validated instruments measuring related constructs. Before data collection, all items underwent face validity review by 2 subject-matter experts to assess clarity and relevance. The

XSL•FO
RenderX

instrument was then pilot-tested with 30 respondents meeting the study eligibility criteria to evaluate item readability and preliminary internal consistency (Cronbach α). Based on the pilot results, several items were reworded for clarity and 1 item was removed before finalizing the instrument. These 30 pilot respondents were not included in the main analytic sample (N=442). All measurement items used a 5-point Likert response format.

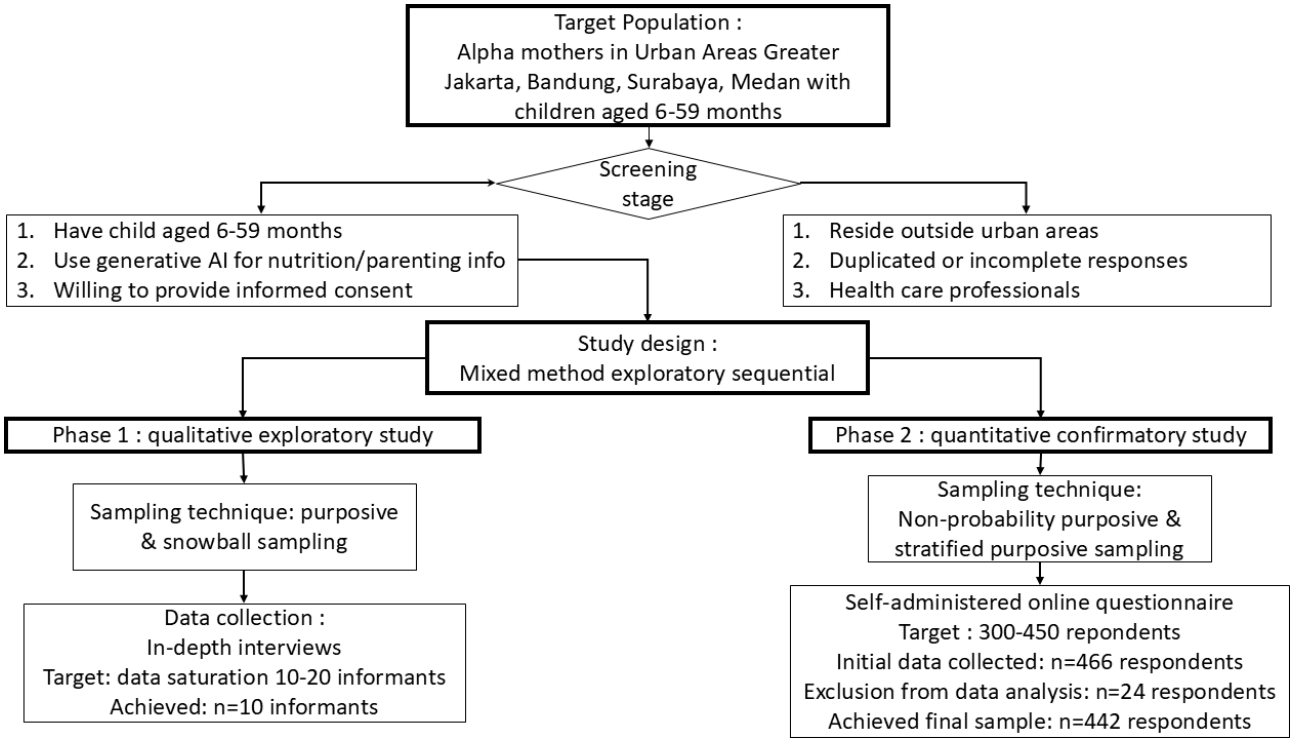
Recruitment and Participant Demographics

The target population, referred to using the descriptive label "Alpha Mothers" as defined in the Introduction section, comprised urban mothers actively engaging with generative AI for child-related information. Eligibility was determined through a 2-stage process: a brief prescreening confirmed current parenting of a child aged 6 - 59 months and prior AI use, while remaining criteria (duration and frequency of AI use, urban residence, and exclusion of health care professionals) were verified through the main survey and manual confirmation by the first author during recruitment. The complete screening and verification items are presented in Multimedia Appendix 1. The geographic scope covered Greater Jakarta, Bandung, Surabaya, and Medan.

For the qualitative phase, recruitment was conducted using purposive and snowball sampling techniques across diverse urban domiciles. The targeted sample size was established at 10-20 key informants, with interviews continuing until theoretical data saturation was achieved and no new themes emerged. In the quantitative phase, participants were recruited via a nonprobability purposive sampling approach.

Outreach efforts strategically used digital parenting communities, pediatric clinic networks, and school communities, channels deliberately selected for their alignment with the digitally literate profile of the target population with implications of this approach for sample composition discussed in the Limitations section. Sample size was determined a priori using G*Power (version 3.1.9.7; Heinrich Heine University Düsseldorf) [42]. Following a recommendation by Hair et al [43], the minimum sample size for PLS-SEM (partial least squares–structural equation modeling) was estimated based on the maximum number of predictors converging on a single endogenous construct in the structural model. The most complex regression equation in the model corresponded to the cognitive empowerment and parental self-compassion constructs, each receiving 5 direct paths from exogenous variables (AI Algorithmic Trust, AI Health Information Quality, AI Personalization Fit, AI Information-Seeking Intensity, and AI Social Proof Sensitivity). With f^2=0.15 (medium effect size), α=.05, and statistical power=0.90, the minimum required sample size was 116 respondents. To ensure proportional geographic representation across the designated urban centers, stratified purposive sampling with regional quotas was applied.

Inclusion criteria stipulated that participants must (1) be mothers residing in the designated urban areas; (2) have at least 1 child aged 6-59 months; (3) actively use generative AI platforms (eg, ChatGPT, Gemini, Grok, etc) for at least 6 months, with a minimum frequency of 3 times per week, to seek childcare and nutritional information; and (4) provide voluntary informed consent to participate in the study. Mothers employed as health care professionals (eg, physicians, nurses, or nutritionists) were excluded from the study. This was a deliberate purposive sampling decision rather than a convenience-based one. Because the study examines how nonexpert mothers perceive, trust, and appraise AI-generated nutrition information, the inclusion of clinically trained mothers would have introduced a systematic confound: such participants evaluate health information through specialized professional knowledge and established clinical standards that differ fundamentally from the lay appraisal processes this study sought to capture [44,45]. Excluding them preserved the conceptual homogeneity of the target population and ensured that the measured constructs reflected lay maternal perception rather than professional clinical judgment. This exclusion was verified manually by the first author (LNA) during recruitment through direct confirmation of occupational status with each potential participant, in addition to the occupation question captured in the main survey. The complete eligibility screening and verification procedure is presented in Multimedia Appendix 1.



Data Collection Procedures

Data collection was conducted sequentially across 2 distinct phases. During the qualitative phase, the first author (LNA) conducted all semistructured in-depth interviews face-to-face over a 3-week period in December 2025. All study materials were administered in Bahasa Indonesia. Interview quotations were translated into English using AI-based tools and verified for meaning equivalence by 2 bilingual team members (FA and SA) against the original transcripts. AI tools were used only for translation and language editing; all coding and thematic analyses were conducted manually. As the quantitative instrument was administered in Bahasa Indonesia, the English wording of the measurement items is for reporting only and did not affect measurement validity. A semistructured guide comprising 16 open-ended questions across 5 core domains (AI trust formation, information quality evaluation, personalization expectations, information-seeking behaviors, and social validation) directed each session, with flexible probing questions to elicit deeper reflection. With participant consent, all sessions were audio-recorded and transcribed verbatim, each lasting 30-45 minutes. To enhance credibility, synthesized member checking following the approach by Birt et al [46] was conducted, returning summarized thematic findings to participants for confirmation.

The quantitative phase data were collected using a self-administered online questionnaire. This survey commenced with a brief screening section to verify that respondents met the designated "Alpha Mother" criteria. Several procedural remedies were implemented to mitigate common method bias (CMB), including randomization of item order within construct blocks, use of psychological separation between predictor and criterion measures, and ensuring respondent anonymity to reduce social desirability concerns [47,48]. Finally, rigorous data-cleaning protocols, including IP address tracking to identify and remove duplicate entries, were implemented prior to statistical analysis. An overview of the data collection process can be seen in Figure 2.

XSL•FO
RenderX

Figure 2. Sampling framework flowchart. AI: artificial intelligence.

Statistical Analysis

Qualitative data from the phase 1 interviews were analyzed using Braun and Clarke's [49] 6-phase thematic analysis framework [50]. Because the interview guide was informed by 5 predefined conceptual domains from prior literature, the analysis followed a hybrid deductive-inductive approach. The predefined domains provided an initial structure for organizing the data, while open coding was used to identify context-specific meanings, indicators, and subthemes within and across those domains. Initial coding was conducted manually by the third author (SA), generating 29 initial codes that were collaboratively grouped into 13 subthemes and consolidated into 5 overarching themes. The coding framework and thematic structure were subsequently reviewed and refined through consensus discussion with LNA and FA to ensure conceptual coherence and that the themes remained grounded in participants' accounts. A complete audit trail linking the predefined domains, interview questions, initial codes, subthemes, final themes, construct definitions, and survey items is provided in Multimedia Appendix 2. Data saturation was assessed iteratively rather than assumed. After each interview, the research team evaluated whether new codes, themes, or subthemes were emerging. No substantive new themes or subthemes were identified across the final 3 consecutive interviews (interviews 8 - 10), indicating that thematic saturation had been reached by the 10th interview. This sample size is consistent with empirical guidance indicating that thematic saturation is typically achieved within 9-17 interviews in studies involving relatively homogeneous populations and narrowly defined research objectives [51], conditions that characterize this study's focus on urban Alpha Mothers.

The first author (LNA), who conducted all interviews, is a mother with personal experience using AI for parenting decisions. This shared identity not only facilitated rapport and nuanced understanding of participants' experiences but also introduced potential for overidentification. To mitigate this risk, initial coding was conducted by the third author (SA), who was not involved in conducting the interviews. The coding framework, subthemes, and final themes were subsequently reviewed and refined through consensus discussions with LNA and FA, helping ensure that interpretations remained grounded in participants' accounts.

Quantitative data from phase 2 were analyzed using PLS-SEM via SmartPLS 4 software (SmartPLS GmbH), following the evaluation guidelines by Hair et al [43]. The evaluation was conducted in 2 primary stages: the measurement model (outer model) and the structural model (inner model). For the measurement model, indicator reliability was assessed using outer loadings. Construct reliability was established using both Cronbach α and composite reliability (CR), while convergent validity was evaluated through the average variance extracted. Discriminant validity was assessed using the Heterotrait-Monotrait (HTMT) ratio of correlations, with thresholds and interpretation criteria following the guidelines of Hair et al [43,52].

Following a satisfactory measurement model, the structural model was evaluated. The overall quality and predictive relevance of the inner model were assessed by examining the inner variance inflation factor (VIF) for collinearity issues, the coefficient of determination (R^2), $Q^2_{predict}$ values, and Cross-Validated Predictive Ability Test (CVPAT) [53,54]. Subsequently, a bootstrapping procedure was applied to test the significance of the 14 proposed research hypotheses, including the moderation effects. Following the a priori structural model, the 5 AI engagement constructs were linked to perceived nutrition-oriented feeding practices only via cognitive

XSL•FO
RenderX

empowerment and parental self-compassion; direct AI engagement-to-outcome paths were not estimated. Consequently, the present analysis does not distinguish direct from indirect associations, and results are interpreted solely as indirect associations rather than as evidence of mediation. Indirect effects were tested using bias-corrected bootstrap confidence intervals, and an effect was considered supported when its 95% CI excluded zero. Finally, an Importance-Performance Map Analysis (IPMA) was conducted to generate actionable insights regarding priority areas for digital health interventions. To assess whether the modeled relationships were consistent across child developmental stages, a bootstrap-based multigroup analysis (MGA) was additionally conducted, comparing mothers of children aged 6 - 24 months with those of children aged 25 - 59 months (Multimedia Appendix 3) [43,55].

Ethical Considerations

All research procedures were conducted in accordance with strict ethical principles for medical and social research. The study protocol was reviewed and approved by the Research Ethics Committee (KEP FEB), Faculty of Economics and Business, Universitas Pelita Harapan, under approval number 047/MARS/EC/XI/2025, issued on November 26, 2025. All recruitment and data collection commenced after this approval was granted. Prior to participation, all individuals were provided with a comprehensive participant information sheet detailing the study's objectives, guarantees of data anonymity and confidentiality, and their right to withdraw at any time without penalty. Explicit informed consent obtained either in writing for the interviews or electronically for the survey was mandatory before any data collection occurred.

Results

Phase 1: Qualitative Exploratory Study

Participant Characteristics

In the first phase of this qualitative study, 10 informants were selected through in-depth interviews until data saturation was reached. All informants were Alpha Mothers with children aged 6 - 59 months, residing in Indonesia's urban centers, including Greater Jakarta, Bandung, Surabaya, and Medan, and frequently using AI as their health care assistant. The informants' characteristics indicated a middle-to-upper socioeconomic profile with a high level of education.

All 10 participants subsequently engaged in the synthesized member-checking process and confirmed that the thematic interpretations accurately reflected their experiences as urban Indonesian mothers navigating AI-assisted child nutrition decisions. No substantive disagreements emerged, and the thematic structure was carried forward to operationalization for the phase 2 quantitative instrument. The participants' employment dynamics were quite diverse, consisting of housewives (n=3), full-time workers (n=3), freelancers (n=2), and professionals (n=2). Most informants had 2 children (n=5), while the remainder had 1 child (n=5), providing a broad perspective from both new and more experienced mothers. Regarding digital literacy, all informants had extensive experience using generative AI (all had more than 6 months of AI use). ChatGPT was the primary platform universally used by all informants, with some participants using additional platforms such as Gemini (n=4), Claude (n=1), and Grok (n=1) to validate children's nutritional information.

Thematic Findings

Hybrid deductive-inductive thematic analysis organized the findings across 5 predefined domains and identified 13 context-specific subthemes (Table 1). These themes explore how Alpha Mothers evaluate, validate, and integrate AI-generated information into their toddler-feeding routines, directly establishing the foundation for the quantitative structural model in phase 2. The first major theme, AI Algorithmic Trust, highlights that maternal trust in AI does not emerge automatically; rather, it is contingent upon perceived technical competence (T1) and moral integrity (T2). Mothers position AI not merely as a search engine but as a stable "thinking partner" expected to provide objective advice free from commercial bias. As one mother emphasized, "I need honest advice...solely focused on my child's health, no commercial bias" (I1). Furthermore, mothers expect the algorithm to align with their core parenting values (T3), seeking an AI that "has the same values and goals" (I8) while maintaining a "strong scientific basis" (I3).

XSL•FO

Table . Thematic exploratory.

Theme	Respondent quotes	Conceptual interpretation
AI[a] Algorithmic Trust		
T1: Competency and Reliability	"I need a thinking partner who is stable, unchanging, and this AI is competent...has a strong scientific basis." [I3]	The perception that AI is a competent and stable expert provides a sense of security, such as technical trust for users.
T2: Moral Integrity and Objectivity	"I need honest advice...solely focused on my child's health, no commercial bias." [I1]	The perception that AI provides honest, genuine advice free from commercial advertising bias.
T3: Value Alignment	"Must have the same values and goals as me...just like chatting with friends on the same wavelength." [I8]	The degree of conformity between AI logic and the parenting principles held by the mother.
AI Health Information Quality		
T4: Accuracy and Completeness	"The data must be accurate...really look for accuracy. It must be complete and thorough...from measurements to allergy risks." [I8]	Information must be proven to be medically accurate and presented in a complete manner.
T5: Relevance	"It's useless if it's not relevant to my child's current condition." [I3]	The accuracy of information in answering specific questions with the user's current conditions.
T6: Understandability	"Don't use complicated language...medical jargons or (seemingly) otherworldly language." [I2]	Use simple language and do not contain complicated medical language.
AI Personalization Fit		
T7: Biological Fit	"I really don't like it when I am given a menu that doesn't suit my little brother's situation... he has allergies...I was even given risky ingredients." [I2]	AI's ability to adapt suggestions to a child's physical limitations for child safety.
T8: Culture and Taste Fit	"Our palate is local...if the food tastes too foreign or too western, children will definitely be turned off." [I2]	Align menu suggestions with local tastes and family eating habits
T9: Practical Fit (Time and Budget)	"It fits the kitchen budget...It fits our time and daily eating habits." [I7]	The level of realism of suggestions regarding the availability of time, energy, and mother's shopping budget.
AI Information-Seeking Intensity		
T10: Search Frequency and Immediate Response	"Going back and forth opening the application, asking again, and again...I have to act quickly, I need an emergency solution right away." [I10]	A behavioral pattern of asking questions repeatedly in a short period of time with the demand for an immediate response.
T11: In-Deep Exploration and Verification Effort	"Keep checking and comparing the answers to be sure. Dig deeper, not just about the menu...but also psychological tricks." [I5]	Efforts to dig deep into the root of the problem while still actively verifying the accuracy of the data.
AI Social Proof Sensitivity		
T12: Mass Acceptance and Herd Safety	"Knowing that this AI is already widely accepted...thousands of other mothers are already using it. I don't want my child to be a guinea pig...there's a sense of security in being in the same group." [I4]	The sense of security that arises from knowing that this technology is already used by the majority of people or mass acceptance.
T13: Validation And Consensus Reliance	"Very necessary for social validation...honest reviews, testimonials...need confirmation from the majority of other users confirming the safety." [I3]	The need for confirmation from a third party in the form of personal testimony or expert opinion before finally being able to trust AI input.

[a]AI: artificial intelligence.

This reliability must be substantiated through rigorous AI Health Information Quality. Mothers demand comprehensive clinical accuracy (T4) and direct relevance to their specific situation (T5), coupled with high understandability (T6). They require thorough data, "from measurements to allergy risks" (I8), while strictly noting that any advice is "useless if it's not relevant to my child's current condition" (I3). Furthermore, to ensure that the information is easily comprehensible, the AI must avoid "medical jargon or (seemingly) otherworldly language" (I2).

Furthermore, objective medical quality must be complemented by AI personalization fit. AI recommendations must be adaptable to the user's specific biological (T7), cultural (T8), and practical realities (T9). Biologically, mothers express strong dissatisfaction when AI fails to account for a child's physical

XSL•FO
RenderX

limitations, such as suggesting “risky ingredients” for a child with allergies (I2). Culturally, suggestions must align with local palates to avoid children being “turned off” by overly Westernized foods (I2). Finally, on a practical level, these recommendations must strictly conform to the mother’s “kitchen budget,” available time, and established daily eating habits (I7).

Interestingly, despite their high digital literacy, Alpha Mothers exhibit pronounced AI Social Proof Sensitivity. There is a distinct reluctance to adopt algorithmic advice without mass acceptance or third-party validation (T12, T13). The psychological safety of adopting AI relies heavily on herd consensus, driven by the fear of making their child a “guinea pig,” thus requiring “honest reviews, testimonials...need confirmation from the majority of other users confirming the safety” (I3, I4).

Finally, this comprehensive evaluation of trust, quality, and social validation drives AI Information Seeking Intensity (T10, T11). During critical situations, such as sudden toddler-feeding strikes, mothers demand immediate, “emergency solutions” (I10). However, they do not accept these answers passively; instead, they engage in intense, repetitive probing to “dig deeper, not just about the menu...but also psychological tricks,” while continuously cross-checking the data for accuracy (I5).

While participants valued AI as a feeding-support tool, their accounts also surfaced consistent negative and critical experiences. The most consequential concerned safety: several mothers reported that AI recommended ingredients unsuitable for their child’s specific medical condition. One mother described that for her allergic child, the AI “even offered risky ingredients” (I2), and another recounted that it suggested a menu whose ingredients “could actually risk making my child sick” (I10). Beyond safety, mothers expressed frustration when AI acted as if it “knew best” yet remained insensitive to their real situation at home (I1, I8), produced culturally mismatched menus that children refused so that the food “ended up wasted” (I3), or kept slipping in hard-to-find ingredients even after being explicitly prompted to avoid them (I6). These experiences indicate that mothers did not engage with AI uncritically; rather, they actively detected, questioned, and worked around its limitations.

These qualitative findings directly informed the quantitative phase of the study. The contextually refined themes and subthemes regarding mothers’ interactions with AI were systematically operationalized into measurable constructs. Table 2 outlines the conceptual definitions of these constructs, which served as the foundation for the survey instrument and structural model testing in phase 2.

XSL•FO
RenderX

Table . Construct definition.

Constructs	Conceptualized definition
AI[a] Algorithmic Trust for Children Nutrition	This construct represents the mother's psychological belief in AI technology for child nutrition which, within the AI parenting nutrition alignment approach, emerges from both a rational assessment of the system's technical reliability and an emotional conviction regarding its integrity and its capacity to provide reassurance consistent with her parenting values [56].
AI Health Information Quality	This construct captures the mother's evaluation of AI-generated nutritional information, focusing specifically on how she perceives its accuracy, completeness, and understandability [21,27].
AI Personalization Fit Perception	AI Personalization Fit Perception reflects the mother's evaluation of how effectively the AI tailors its nutritional guidance to her specific reality. This encompasses her child's biological health status, her own psychological preferences, and her immediate environmental or situational context [57].
AI Information-Seeking Intensity	AI Information-Seeking Intensity represents the frequency, duration, and depth of mother's engagement with AI to obtain and verify nutritional information [58,59]. Within this study, a high intensity of use reflects the mother's active alignment efforts to navigate and resolve digital uncertainty.
AI Social Proof Sensitivity	AI Social Proof Sensitivity characterizes a mother's responsiveness to collective validation signals, such as app reviews, ratings, and overall popularity [60,61]. Within the AI parenting nutrition alignment approach, this reflects a herd—safety tendency, illustrating how mothers seek safety in numbers as a form of collective validation before adopting new health technologies.
Cognitive Empowerment in Health Decision-Making	Cognitive Empowerment in Health Decision-Making refers to a mother's psychological and cognitive capacity to understand, evaluate, and use AI-generated information for practical toddler nutrition decisions. This construct is heavily dependent on her language comprehension and critical appraisal skills [36,62].
Parental Self-Compassion in Feeding Context	Adapted from Hasyyati and Abidin [63], this construct captures a mother's ability to approach toddler-feeding challenges with self-compassion, which operationally involves practicing self-kindness, viewing feeding setbacks through the lens of common humanity, and sustaining mindfulness to preserve emotional balance.
eHealth Self-Efficacy	eHealth Self-Efficacy refers to a mother's perceived confidence in her ability to effectively find, evaluate, and resolve toddler-feeding challenges using AI and other digital technologies [22,26].
Perceived Nutrition-Oriented Feeding Practices	Perceived Nutrition-Oriented Feeding Practices reflects a mother's subjective evaluation of the nutrition-focused feeding strategies she implements for her child, distinct from observed feeding behavior or objective child nutrition outcomes. Operationally, this encompasses meal schedule consistency, deliberate nutritional appraisal of foods offered, limitation of low-nutrient foods, and attentiveness to the child's satiety signals. Within the food parenting practices content map, these correspond primarily to the structure domain and, in part, to nutrition education within autonomy support; the construct does not operationalize coercive control practices or child autonomy support in full and therefore does not represent the complete responsive feeding construct as defined by WHO[b] and UNICEF[c] [64-66].

[a]AI: artificial intelligence.

[b]WHO: World Health Organization.

[c]UNICEF: United Nations Children's Fund.

Phase 2: Quantitative Explanatory Predictive Study

The second phase of this study used a quantitative survey to empirically validate the structural model derived from the qualitative findings. Specifically, this phase evaluated perceived nutrition-oriented feeding practices, operationalized as maternal self-report, not observed feeding behavior or objective child nutrition outcomes. The model then tested how nutrition-oriented feeding practices are associated with 5 AI-related predictors via 2 intervening constructs, cognitive empowerment (CE), and parental self-compassion (PSC), with eHealth self-efficacy (ESE) as a moderator.

XSL•FO
RenderX

Participant Characteristics

A total of 442 respondents completed the survey and met all inclusion criteria, substantially exceeding the minimum sample size of 116 derived from the a priori power analysis. This sample size provided robust statistical power for testing the proposed structural model. Geographic distribution was concentrated in the Greater Jakarta area (255/442, 57.7%). Demographically, the largest segment of mothers was aged 31-35 years (184/442, 41.6%).

Reflecting the “Alpha Mother” profile, over half held a bachelor’s degree (227/442, 51.4%), with a substantial proportion possessing postgraduate degrees (155/442, 35.1%). Socioeconomically, the predominant employment status was full-time office worker (139/442, 31.4%), followed closely by professionals (111/442, 25.1%). Routine monthly household expenditure primarily fell between US $292.18 and US $584.36 (217/442, 49.1%). Regarding family dynamics, nearly half of the participants had 2-3 children (217/442, 49.1%), and the target toddlers were most commonly aged between 37 and 59 months (169/442, 38.2%). ChatGPT emerged as the most frequently used AI platform for health information (259/442, 58.6%), followed by Gemini (125/442, 28.3%). A comprehensive breakdown of these participant demographics and characteristics is presented in Table 3.

AI Usage for Child Nutrition

To understand exactly how these mothers relied on AI for toddler feeding, we asked them to identify their most frequent search topics. Respondents could select multiple options, so percentages total more than 100%. The data show that they primarily turned to AI for day-to-day nutritional optimization. More than half of the mothers searched for information on child growth supplements (237/442, 53.6%) and the nutritional value of various foods (235/442, 53.2%). A full breakdown of these search topics is available in Multimedia Appendix 4.

Measurement Model Evaluation

The measurement model was evaluated by examining indicator reliability, construct reliability, convergent validity, and discriminant validity. Indicator reliability was assessed through outer loadings, which ranged from 0.739 to 0.918, indicating that the majority of indicators adequately represent their respective constructs. Construct reliability was examined using Cronbach α and CR (rho_c). Cronbach α values ranged from 0.833 to 0.916, and rho_c values ranged from 0.882 to 0.941, all exceeding the recommended threshold of 0.70, demonstrating acceptable internal consistency. Convergent validity was evaluated through the average variance extracted, which ranged from 0.600 to 0.800, suggesting that more than half of the variance of each indicator was explained by the corresponding construct. These results indicate that the instrument demonstrates sufficient reliability and validity. Detailed values for each construct are presented in Table 4.

Table . Construct validity and reliability results. Indicator codes NFP1–NFP5 correspond to FPQ1-FPQ5 in the SmartPLS output (Figure 3), which retains the original instrument coding.

Variable and code	Indicator	OL[a]
AI[b] Algorithmic Trust (AT)[c]		
AT1	I feel this AI provides pretty consistent nutritional advice for my child.	0.844
AT2	I believe this AI algorithm has accurate processing capabilities, thus minimizing errors in child nutrition recommendations.	0.875
AT3	I believe this algorithm was designed objectively without bias.	0.802
AT4	I know that the AI I use is not directed towards hidden commercial interests (eg, promotion of a particular brand).	0.764
AT5	I feel that this AI's advice aligns with my needs as a mother in managing my child's nutrition.	0.827
AI Health Information Quality (IQ)[d]		
IQ1	I consider the nutritional information provided by this AI to be accurate according to credible health references.	0.743
IQ2	The answers given by AI regarding children's nutrition are complete and comprehensive.	0.763
IQ3	The menu suggestions provided by AI are appropriate to my child's age and specific needs.	0.845
IQ4	Information from AI is presented in language that is easy for mothers like me to understand.	0.825
IQ5	I think the information from this AI is not contaminated by certain political interests.	0.825
AI Personalization Fit (PF**)** Perception[e]		
PF1	I feel that the food recommendations from AI are appropriate for my child's growth stage.	0.805
PF2	I feel that the food suggestions from AI are quite in line with my child's appetite.	0.802
PF3	I feel that the AI's grocery suggestions are still within my family's spending power.	0.789
PF4	I feel that I can implement the AI's suggestions in the midst of my daily activities.	0.761
PF5	I feel that the AI's suggestions are in line with my child's physical needs.	0.861
AI Information-Seeking Intensity (ISI)[f]		
ISI1	I often use AI applications to get the information I need.	0.836
ISI2	I often use AI to check information from other sources.	0.846
ISI3	I often ask AI if I need ideas for doing something.	0.850
ISI4	I usually ask questions over and over again so that I really understand the information I need.	0.758
AI Social Proof (SP) Sensitivity[g]		
SP1	I felt more confident in AI when I learned that many other mothers were using it too.	0.878

XSL•FO
RenderX

Variable and code	Indicator	OL[a]
SP2	Knowing that this app is used by so many people makes me even more confident in the accuracy of this AI.	0.918
SP3	I tend to choose AI that is popular among mothers because I believe that "the more users, the less error in the AI."	0.893
SP4	If the majority of mothers share positive stories about an AI, then I will be more likely to believe in this AI.	0.887
Cognitive Empowerment (CE) in Health Decision-Making[h]		
CE1	This AI encouraged me to learn to understand the nutritional terms needed in child nutrition planning.	0.812
CE2	Using AI has made me understand better how to measure children's nutritional content.	0.880
CE3	It became easier for me to conclude the information provided by this AI through the explanations given in a coherent manner.	0.846
CE4	I have become better able to sort out information from AI that is useful for addressing my child's nutritional issues.	0.861
CE5	I was taught by AI to be more independent when making decisions about managing my child's nutrition.	0.808
Parental Self-Compassion (PSC) in Feeding Context[i]		
PSC1	I can stay calm when my child's meal plan doesn't go as expected.	0.808
PSC2	I feel more at ease knowing that toddler food refusal behavior is a common experience among mothers, not a reflection of my own parenting failure.	0.820
PSC3	I don't blame myself when my child refuses to eat the healthy food I have prepared.	0.817
PSC4	I have learned to manage my stress response when my child refuses to eat during mealtimes.	0.750
PSC5	I don't beat myself up too much when my kids' food choices don't always go according to plan.	0.783
eHealth Self-Efficacy (ESE)[j]		
ESE1	I am confident using AI to help me solve my child's eating problems.	0.797
ESE2	I am confident that I can find other reliable sources of information if the AI's advice on children's diet does not suit my child's condition.	0.844
ESE3	I am confident that I can find a variety of menus that suit my child's nutritional needs through appropriate AI prompting (giving instructions or questions).	0.813
ESE4	I am confident that I can ask or give orders to the AI myself without the help of others.	0.842
Perceived Nutrition-Oriented Feeding Practices (NFP)[k]		
NFP1	I can usually recognize the signs of fullness in my child correctly.	0.752

XSL•FO
RenderX

Variable and code	Indicator	OL[a]
NFP2	Generally, I have consistently implemented a regular schedule for main meals and snacks.	0.790
NFP3	I am able to limit giving my child less nutritious food.	0.753
NFP4	I usually think about what kind of food is healthy enough for my child every day.	0.835
NFP5	I always read the nutritional content on the packaging of food prepared for my child.	0.739

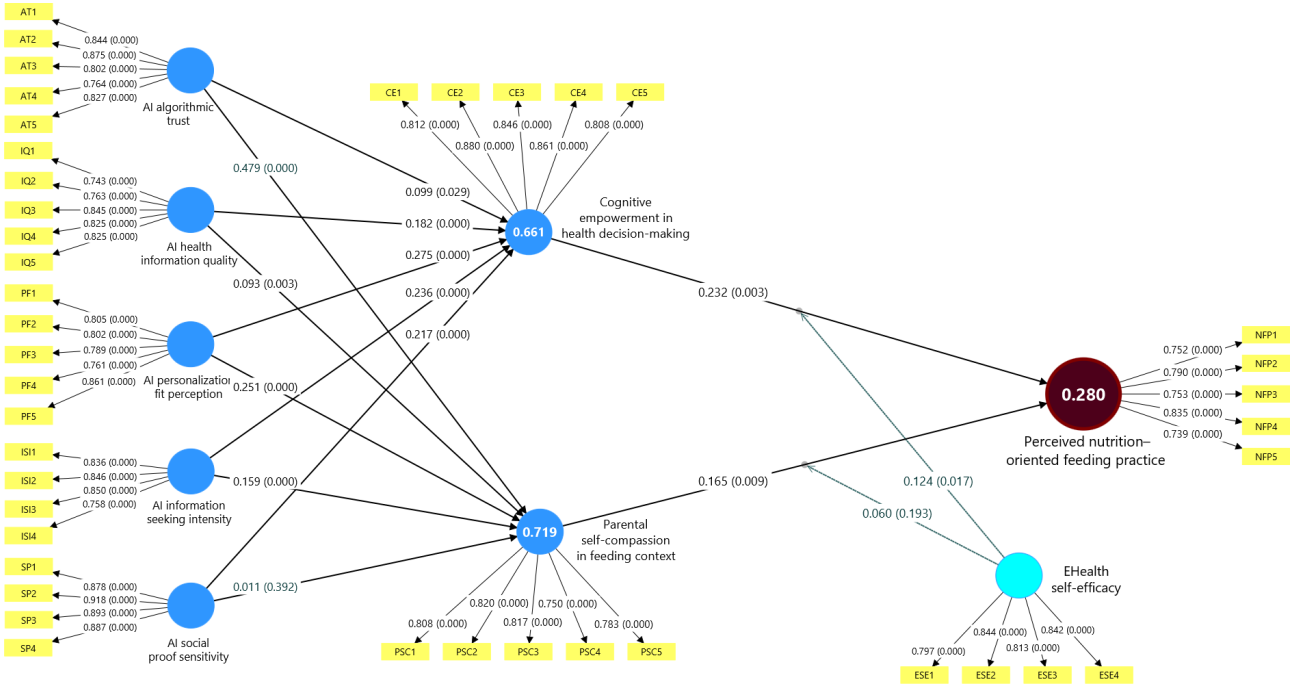
Discriminant validity was rigorously evaluated using the HTMT ratio criteria, which can be seen in the Multimedia Appendix 5. The analysis results indicate that all constructs have adequately met the discriminant validity criteria. The research data recorded the highest HTMT ratio of 0.922 in the relationship between the AI Algorithmic Trust (AT) construct and Parental Self-Compassion in Feeding Context (PSC). This study then applied further testing in the form of an HTMT inference test to evaluate the high ratio in this relationship. The test results proved that the upper limit of the 90% confidence interval (bias-corrected) was at 0.955. This result supports the empirical distinctiveness between constructs, as the upper confidence bound falls below the absolute threshold of 1.000, indicating that all constructs in this study meet the discriminant validity criteria.



Structural Model and Hypothesis Testing

Before evaluating the structural paths, the model was assessed for multicollinearity and potential CMB. Following the full collinearity assessment approach proposed by Kock [67], the inner VIF was examined for all predictor constructs. As shown in Multimedia Appendix 6, all inner VIF values ranged from 1.376 to 2.785. Since these values fall below the conservative threshold of 3.3, the predictor constructs can be considered empirically independent, and CMB is unlikely to be a serious concern in this dataset

Based on the out-of-sample predictive power evaluation using PLSpredict, all latent variables yielded $Q^2_{predict}$ values greater than zero: Cognitive Empowerment in Health Decision-Making (0.992), Parental Self-Compassion in Feeding Context (0.994), and Perceived Nutrition-Oriented Feeding Practices (0.989)—indicating low descriptive prediction error at the construct level. These values, while notably high, are consistent with the strong construct reliability observed in the measurement model (Cronbach α 0.833 - 0.916, CR 0.882 - 0.941) and the large sample size (N=442), both of which enhance out-of-sample predictive stability [68]. Because $Q^2_{predict}$ is a descriptive metric based on error reduction, predictive validity was further examined through the CVPAT, which compares model performance against 2 benchmarks of increasing stringency: the naive indicator average (IA) and the stricter linear model (LM). Against IA, the model produced significant improvements across all constructs (P<.001). Against LM, only the overall row simultaneously produced a negative average loss difference and a significant P value of .024—a combination that under CVPAT constitutes formal predictive validity at the aggregate model level. Future replications should interpret construct-level predictive advantages with caution. Following this validation, the complete structural model, detailing the path coefficients and variance explained, is illustrated in Figure 3.

XSL•FO
RenderX

Figure 3. Structural (inner) model estimated with PLS-SEM. Circles represent latent constructs and yellow rectangles their measured indicators. Light blue circles denote the exogenous predictors and the 2 mediators; the cyan circle denotes eHealth self-efficacy, modeled as a moderator (interaction effects shown as dashed teal arrows); and the dark red circle denotes the endogenous target construct. Arrow values are path coefficients with P values within parentheses, and values within the endogenous circles are R^2 values. AI: artificial intelligence; PLS-SEM: partial least squares–structural equation modeling.

The CVPAT was used to evaluate the model's out-of-sample predictive capabilities. As shown in Table 5, the PLS-SEM produced significantly lower prediction errors than the naive IA benchmark across all constructs and the overall model (P<.001). When compared against the more conservative LM benchmark, the overall model demonstrated a significantly negative average loss difference (P=.02), although individual constructs (CE and PSC) did not reach statistical significance against this benchmark. Based on the overall model's significantly lower prediction errors relative to both the IA and LM benchmarks, the model demonstrates adequate predictive validity at the aggregate level.

Table . Cross-Validated Predictive Ability Test.

Variable	PLS-SEM[a] versus IA[b]				PLS-SEM versus LM[c]			
	PLS loss	IA loss	Average loss difference	*P* value	PLS loss	LM loss	Average loss difference	*P* value
CE[d]	0.280	0.515	−0.235	<.001	0.280	0.287	−0.007	.30
PSC[e]	0.273	0.496	−0.223	<.001	0.273	0.276	−0.002	.62
NFP[f]	0.364	0.430	−0.066	<.001	0.364	0.384	−0.020	.05
Overall	0.305	0.480	−0.175	<.001	0.305	0.315	−0.010	.02

[a]PLS-SEM: partial least squares–structural equation modeling.

[b]IA: indicator average.

[c]LM: linear model.

[d]CE: cognitive empowerment in health decision-making.

[e]PSC: parental self-compassion in feeding context.

[f]NFP: perceived nutrition-oriented feeding practices.

Of the 14 hypotheses tested, 12 were supported, while 2 (H10 and H14) were not supported as zero fell within their confidence interval ranges. This indicates insufficient evidence that AI Social Proof Sensitivity is associated with Parental Self-Compassion (H10), or that eHealth Self-Efficacy significantly moderates the relationship between Parental Self-Compassion and Perceived Nutrition-Oriented Feeding Practices (H14). Among the independent variables, AI Algorithmic Trust showed the strongest association with Parental Self-Compassion (β=.479; P<.001), while AI Personalization Fit Perception showed the strongest association with Cognitive Empowerment (β=.275; P<.001). Cognitive Empowerment demonstrated a stronger association with Perceived Nutrition-Oriented Feeding Practices (β=.232; P=.003) than

XSL•FO
RenderX

did Parental Self-Compassion (β=.165; *P*=.009). For the moderation analysis, eHealth Self-Efficacy significantly strengthened the pathway from Cognitive Empowerment to Perceived Nutrition-Oriented Feeding Practices (β=.124; *P*=.02). The predominance of small f^2 values reflects the model's indirect association architecture rather than weak associations. Because 5 correlated AI engagement predictors converge on each intervening construct, the incremental variance of any single path is necessarily diluted, even as the collective R^2 remains substantial (0.661; 0.719). The negligible effects (H1, f^2=0.011; H12, f^2=0.017; and H13, f^2=0.018) operate reliably in the hypothesized direction while adding little unique variance once stronger predictors are accounted for; this pattern also applies to H13, given that interaction terms are typically smaller than main effects in behavioral models [69]. The single medium effect, AI Algorithmic Trust → Parental Self-Compassion (H2, f^2=0.293), identifies the emotional trust pathway as the model's most prominent association, consistent with the difficulty of explaining feeding outcomes from psychosocial predictors alone. A bootstrap MGA comparing mothers of children aged 6 - 24 months (n=136) and 25 - 59 months (n=306) found no statistically significant differences across any of the structural paths (all *P*>.05; smallest difference *P*=.13), indicating that the modeled associations were stable across this age range (Multimedia Appendix 3). The complete hypothesis testing results are presented in Table 6.

XSL•FO

Advanced Analytics

AI engagement constructs were related to perceived nutrition-oriented feeding practices via both intervening constructs. Nine of 10 specific indirect effects and all 5 total indirect effects were supported, with the strongest indirect association via cognitive empowerment. The pathway from AI social proof sensitivity through parental self-compassion was not supported, consistent with H10. As the model included no direct paths, these are reported as indirect associations; because no direct paths were estimated, mediation is not inferred. Full results are reported in Multimedia Appendix 7. In addition, this study also applies IPMA to evaluate intervention priorities practically (Figure 4).

Figure 4. Importance-Performance Map Analysis indicators. CE: cognitive empowerment; ESE: eHealth self-efficacy; PSC: parental self-compassion.

The IPMA identified 4 indicators positioned in the high-importance, low-performance quadrant, signaling priority areas for future intervention development. PSC1 (staying calm when meal plans do not go as expected) and PSC2 (feeling at ease knowing toddler food refusal is a common experience) both reflect the emotional regulation dimension of parental

XSL•FO
RenderX

self-compassion—suggesting that AI-assisted feeding tools may need to incorporate emotional support and normalization features rather than focusing solely on informational content. ESE1 (confidence in using AI to solve child eating problems) indicates that user confidence in AI-based feeding solutions is a key gap, pointing to the need for progressive skill-building and user onboarding features. CE5 (learning to be independent in nutrition decisions through AI) suggests that AI platforms should scaffold—rather than replace—maternal decision-making autonomy. Together, these indicators suggest that future AI-assisted feeding tools should prioritize emotional support, confidence-building, and decision autonomy alongside informational accuracy. The mapping results showed that the data distribution placed indicators of parental self-compassion (PSC1 and PSC2), eHealth self-efficacy (ESE1), and cognitive empowerment (CE5) in areas of high importance with low performance. These findings may help identify potential priorities for future intervention development.

Discussion

Principal Findings

This mixed methods study investigated how urban Indonesian Alpha Mothers, a digitally literate, highly educated, and evidence-driven caregiver profile, had an increasing engagement with generative AI as a decision support partner in toddler feeding. Beyond the structural model, the qualitative phase contextually refined 5 literature-informed AI engagement dimensions relevant to maternal AI-mediated toddler feeding—algorithmic trust, health information quality, personalization fit perception, information-seeking intensity, and social proof sensitivity. Although these dimensions align with existing constructs in the literature, their context-specific refinement through mothers' lived experiences and their integration into a single framework for this specific context represent the study's principal qualitative contribution. The quantitative outcome examined was maternal perception of nutrition-oriented feeding practices and not observed feeding behavior or child nutrition outcomes. The findings suggest that associations between AI engagement and perceived nutrition-oriented feeding practices may involve 2 distinct indirect associations: 1 cognitive and 1 emotional. Mothers who trusted AI and found its recommendations relevant to their child's feeding context were better able to evaluate and adapt its suggestions on their own terms. Mothers who perceived AI as nonjudgmental and objective reported lower maternal guilt. In this study, it is captured as parental self-compassion. Both pathways were independently associated with better perceived nutrition-oriented feeding practices, although the cognitive pathway carried greater weight.

Four findings warrant closer attention. AI algorithmic trust was the strongest predictor of parental self-compassion, suggesting that lower emotional burden may be more closely associated with trust in the AI system rather than with its popularity. AI personalization fit perception was the strongest predictor of cognitive empowerment, more so than algorithmic trust, information quality, or information-seeking intensity. Alpha Mothers do not appear to value accurate AI content alone. The findings suggest that they also value advice tailored to their child, daily routines, and cultural feeding practices. Beyond personalization, AI social proof sensitivity predicted cognitive empowerment but had no bearing on parental self-compassion. Community support, whether in the form of ratings, peer recommendations, or popularity signals, may shape a mother's opinion about AI. Yet, it will not affect her inner convictions as a parent. Self-compassion in this context comes from personal experience and not from external reassurance.

Finally, eHealth self-efficacy strengthened the pathway from cognitive empowerment to nutrition-oriented feeding practices. However, it played no moderating role in the self-compassion pathway. Digital confidence and emotional self-regulation appear to be separate capacities that call for separate intervention approaches. The findings suggest that AI may serve as a supportive tool that complements, rather than replaces, maternal judgment and professional nutrition counseling.

Comparison With Prior Work

Algorithmic trust emerged as the strongest predictor of parental self-compassion in this study. In the digital health literature, trust in AI has largely been treated as a functional matter, assessed through criteria of technical performance, accuracy, and system credibility [70]. Less attention has been paid, however, to whether trust in AI also carries an emotional function. Recent empirical work suggests that patients' experiences with AI health systems extend well beyond rational cost-benefit evaluation, with emotional responses such as anxiety, cognitive overload, and resistance playing a significant role in how users actually engage with these tools [71,72]. The concept of algorithmic authority provides a framework for interpreting this emotional dimension.

The present findings add a maternal caregiving dimension to this picture. For these urban Indonesian mothers, trusting an AI system was not simply a matter of judging whether its nutritional advice was clinically sound. It also determined whether that trust could absorb some of the guilt and cognitive load that accompanies daily toddler-feeding decisions. AI-driven pediatric tools may benefit from being designed with this emotional function in mind, not only to improve informational output but also to offer meaningful psychological relief to the caregivers who rely on them.

Trust in health AI has been shown to rest less on technical performance than on the degree to which a system reflects the user's own values and ways of knowing [73]. For the Alpha Mothers in this study, factual accuracy was merely a baseline. Qualitative findings suggest that trust was closely tied to perceptions of commercial neutrality and value alignment.

The result indicated that AI personalization fit perception was the strongest predictor of cognitive empowerment compared with the other 4 variables. The dominance of AI personalization as a predictor of cognitive empowerment in these findings aligns with existing literature on parental digital behavior. This pattern is consistent with findings that parents of preschool children prioritize family-adapted technology over standardized content [57,74,75]. The findings suggest that mothers in this study preferred highly contextualized nutritional guidance. This

XSL•FO
RenderX

finding is consistent with the interpretation that for this demographic, personalization is the strongest predictor associated with cognitive empowerment.

However, this study structural model also reveals that this technology-driven empowerment has distinct boundaries, particularly concerning the emotional complexities of parenting. Specifically, the rejection of the hypotheses regarding AI Social Proof Sensitivity (H10) and the moderating role of eHealth Self-Efficacy (H14) indicates that while AI can cognitively empower mothers, technical and social features were not associated with higher levels of Parental Self-Compassion in this study. Knowing that other mothers use AI (social proof) or possessing high technical skills to navigate health information (eHealth self-efficacy) does not organically translate into reduced maternal guilt or enhanced emotional grace when facing feeding challenges.

The nonsignificant relationship between AI social proof sensitivity and parental self-compassion may reflect a dynamic specific to digital parenting environments. When mothers evaluate AI guidance through the lens of social proof, they are simultaneously exposed to a wide and often contradictory range of parenting standards. Far from offering reassurance, this collective validation tends to fuel upward social comparison and maternal competition. Recent empirical research indicates that exposure to heterogeneous parenting norms in digital spaces intensifies the internalization of an unrealistic “good mother” ideology [18,76]. True self-compassion requires self-kindness and the acceptance that all parents struggle. However, this mindset is incredibly hard to maintain in digital spaces that constantly push idealized standards, leaving mothers feeling like they fall short. High sensitivity to social proof, in this reading, does not appear to soften self-judgment and may instead be associated with greater self-criticism.

eHealth self-efficacy moderated the cognitive empowerment pathway but not the pathway from parental self-compassion to nutrition-oriented feeding practices. Digital self-efficacy has been shown to associate positively with health self-management behaviors through chain mediation in general population samples [77]. The divergence in these findings reflects the nature of self-compassion itself. Cognitive empowerment involves active information processing and responds to greater digital confidence. Self-compassion, by contrast, is an affective response rooted in self-acceptance. A mother’s ability to navigate health platforms does not make her more forgiving of herself when feeding goes wrong. These 2 observed patterns may reflect differences in the underlying psychological constructs and require different intervention approaches. Ultimately, these different paths lead to the question: what can a model focused on AI engagement realistically explain?

Taken together, these findings can be interpreted through the algorithmic authority lens introduced earlier [32]. This interpretation is offered as a theoretical reading of the cross-sectional associations observed in this study rather than as a directly tested causal account. The strongest pathway, from AI algorithmic trust to parental self-compassion, may be consistent with early-stage algorithmic authority formation, in which higher trust is associated with reliance on AI not only for information but also for emotional reassurance. Within this theoretical framing, such reliance could mark the point at which AI begins to substitute for, rather than support, maternal judgment, although the present data cannot establish whether this substitution actually occurs. The nonsignificant association for H10 refines this picture: in maternal caregiving, awareness that other mothers use AI was not associated with parental self-compassion, a pattern interpreted here as peer signals inviting social comparison rather than reassurance [18,76]. The moderation finding adds further insight: eHealth self-efficacy strengthened only the cognitive pathway, suggesting that digital literacy helps mothers think critically about AI advice but does not protect them from becoming emotionally dependent on it.

Together, these patterns may suggest, at a theoretical level, that conditions for algorithmic authority are most pronounced when high trust in AI coexists with low emotional resilience, the pattern the AI parenting nutrition alignment approach is intended to address. This raises a conceptual concern about potential algorithmic dependency: if high trust in AI and emotional relief through its use were to develop together, mothers might progressively reduce consultations with health care professionals, perceiving clinical guidance as less necessary [32,42]. Consequently, AI-generated inaccuracies may remain undetected, potentially delaying appropriate referral when a child presents with genuine nutritional concerns. In the toddler-feeding domain specifically, these risks take concrete forms: AI-generated advice may recommend age-inappropriate foods, overlook individual allergies, or suggest incorrect nutrient dosages [28], concerns corroborated by qualitative participants who reported receiving recommendations containing potentially harmful ingredients for their child’s condition. Because detecting such errors depended on the mother’s own vigilance, the risk was unevenly distributed—least for mothers with stronger nutritional knowledge and critical appraisal skills, and greatest for those most reliant on AI. This remains a hypothesized risk that the cross-sectional design cannot confirm and that warrants longitudinal investigation.

The effect size pattern warrants careful interpretation. AI Algorithmic Trust showed the strongest contribution to Parental Self-Compassion, while the other supported pathways showed smaller contributions. Some pathways, although statistically significant, contributed only modestly to the outcome. Two factors help explain this pattern. First, nutrition-oriented feeding practices are shaped by many caregiving factors, such as economic, cultural, situational, and child-specific factors that fall outside any AI engagement model. Second, moderation effects are typically smaller than main effects in behavioral models [69]. The findings should therefore be read as statistically robust but practically modest contributions of AI engagement to perceived nutrition-oriented feeding practices, rather than as evidence that AI engagement is the dominant driver of nutrition-oriented feeding practices. The same reality is reflected in the modest overall explanatory power for nutrition-oriented feeding practices. This suggests that AI engagement, together with the 2 intervening constructs, captures only part of what shapes feeding practices, with substantial remaining variance attributable to factors outside the model, such as socioeconomic conditions, family food culture, child

XSL•FO
RenderX

temperament, maternal mental health, and situational demands. Furthermore, perceived measures of caregiving behavior—as opposed to directly observed practices—are known to be shaped by momentary contextual influences and subjective interpretation, which further constrains the variance explainable by any structural predictor set. Structural models targeting behavioral outcomes rarely explain more than a small proportion of variance, even when theory-driven and methodologically robust. The identification of algorithmic trust and parental self-compassion as significant psychosocial pathways therefore represents a meaningful contribution within this explanatory context. The perceived nutrition-oriented feeding practices construct in this model captures the nutritional and structural dimensions of infant and young child feeding guidance, namely, schedule consistency, nutritional appraisal, and limitation of low-nutrient foods, together with attentiveness to satiety signals. It does not operationalize the reciprocal responsiveness components central to the WHO or UNICEF definition of responsive feeding, which additionally require assessment of coercive feeding pressure and child autonomy support [5,6]. While the findings suggest that AI engagement may reinforce these nutrition-oriented practices via its association with cognitive empowerment, current AI platforms remain unbenchmarked against WHO or UNICEF responsive feeding frameworks or the structured competencies delivered through the UNICEF C-IYCF Counselling Package [25]. AI-assisted feeding support should therefore complement, not replace, established C-IYCF counseling models.

Implications

The following implications should be interpreted as preliminary directions derived from cross-sectional associations rather than as established prescriptions. The policy, clinical practice, and system development levels outlined in this section each warrant validation through longitudinal investigation, intervention trials, and contextual adaptation prior to large-scale implementation. At the policy level, these findings highlight the growing importance of governance frameworks for AI-assisted parenting and nutrition support. As generative AI becomes increasingly integrated into health care, international guidance has emphasized transparency, accountability, safety, and human oversight in AI-enabled health systems [78,79]. Indonesia has similarly established foundational principles for responsible AI development through Ministerial Circular No. 9/2023 [80]. However, no dedicated framework currently addresses AI-generated child nutrition advice or clearly defines accountability when such advice is associated with harm. Future policy efforts may therefore benefit from establishing standards for transparency, evidence attribution, and alignment with WHO and UNICEF responsive feeding guidance, while ensuring that AI-assisted nutrition support complements rather than replaces professional nutrition counseling.

At the clinical practice level, the findings suggest that pediatricians, nutritionists, and public health practitioners may increasingly serve as facilitators who help mothers critically evaluate AI-generated nutrition advice and integrate it with professional guidance and their child's individual circumstances. Within the Indonesian context, future research may explore whether AI literacy and nutrition counseling can be incorporated into existing maternal and child health services, including Posyandu and routine well-child care. Such approaches should position AI as a complement to, and not a substitute for, professional nutrition counseling while strengthening maternal cognitive empowerment and critical appraisal skills.

At the system development level, the findings provide preliminary insights that may inform future AI-assisted feeding support tools. The AI Parenting Nutrition Alignment Approach highlights the potential value of contextualized guidance, transparent explanations, and support for critical evaluation of AI-generated recommendations. Future systems may also benefit from benchmarking against WHO and UNICEF responsive feeding guidance to improve consistency with evidence-based nutrition recommendations. Development and implementation of such tools would likely require collaboration among pediatricians, nutritionists, public health practitioners, AI developers, and policymakers to ensure appropriate clinical oversight, safety, and governance. However, these implications remain conceptual and require evaluation through longitudinal and intervention-based research before broader implementation.

Limitations

Several limitations should be acknowledged. First, the sample was drawn from a specific demographic profile—urban, digitally active mothers who actively use generative AI—referred to in this study using the descriptive label "Alpha Mother." This label functions as a recruitment descriptor rather than a validated theoretical construct, and findings should not be generalized beyond this defined demographic profile. Whether the patterns observed here apply to mothers from different socioeconomic, educational, or digital engagement profiles remains an open empirical question. Second, recruitment through digital parenting communities likely introduced self-selection bias toward mothers already favorably disposed toward generative AI. Findings should therefore be interpreted as reflecting the experiences of digitally active, AI-engaged urban mothers rather than urban Indonesian mothers more broadly.

Third, all data relied on self-report. Mothers may have overstated their trust in AI or their sense of self-compassion to align with perceived parenting ideals, particularly given the social pressures that surround toddler feeding in urban Indonesian contexts. Furthermore, perceived nutrition-oriented feeding practices capture maternal self-assessment, not observed feeding behavior or objective child nutrition outcomes. The instrument assesses nutrition-focused and structural aspects of feeding; coercive feeding pressure, caregiver responsiveness to the full range of hunger and satiety cues, and child autonomy support were not measured. Findings therefore speak to the nutritional and structural dimensions of feeding rather than to caregiver-child interactional quality and should not be read as evidence regarding responsive feeding as defined by WHO and UNICEF. Future work should triangulate this construct against behavioral instruments such as the Comprehensive Feeding Practices Questionnaire and against anthropometric indicators.

Fourth, the cross-sectional design and the modest variance explained limit interpretation. The associations identified through PLS-SEM are statistically robust but cannot establish whether AI engagement changes maternal behavior over time,

XSL•FO
RenderX

and the low explained variance indicates that AI engagement is only one of several factors shaping feeding practices. The design also permits alternative explanations the present data cannot adjudicate: the trust-outcome relationship may be reversed or reciprocal, as mothers who already possess greater feeding confidence, knowledge, or emotional resilience may be more predisposed to trust AI and report favorable feeding experiences. An unmeasured third variable, such as general health literacy or socioeconomic advantage, could likewise elevate both, and such confounding is difficult to exclude given the self-selected sample. The reported associations should therefore be read as compatible with, but not confirmatory of, the mechanistic interpretation advanced in the Principal Findings section. Improvements in perceived nutrition-oriented feeding practices should therefore not be interpreted as evidence of improved child nutritional or developmental outcomes. In addition, although the sample spanned a broad age range (6‐59 months), an MGA confirmed that the structural estimates did not differ significantly between younger and older children (Multimedia Appendix 3); the younger stratum nonetheless follows the survey's 6‐ to 24-month category, 1 month wider than the WHO 6‐ to 23-month cutoff, and its smaller size warrants caution in interpreting subgroup estimates.

Fifth, social desirability and CMB cannot be fully excluded, as all constructs were self-reported through a single instrument at one time point. Although procedural remedies and a full collinearity assessment (all inner VIF <3.3) indicate that CMB is unlikely to be severe, these safeguards reduce rather than eliminate the risk. In addition, the 5 AI engagement dimensions were newly developed here and have not been externally validated, and the AI parenting nutrition alignment approach that organizes them adapts an existing framework [44] not yet validated in this domain. Findings involving them should be regarded as preliminary.

Finally, this study did not independently audit the clinical accuracy of AI-generated nutritional advice received by participants; the constructs measured reflect mothers' perceptions of AI quality rather than objective evaluation of AI output. Future research should systematically benchmark AI-generated feeding advice against WHO or UNICEF responsive feeding recommendations and the C-IYCF counseling competency framework, a critical step toward developing clinically validated AI-assisted feeding platforms.

Conclusions

This mixed methods study suggests that generative AI is not independently associated with perceived nutrition-oriented feeding practices. Associations between AI engagement and perceived nutrition-oriented feeding practices were strongest when mothers trusted the system and perceived its recommendations as fitting their child and household realities. Two distinct indirect associations may help describe these associations. Algorithmic trust was associated with parental self-compassion, which was linked to lower emotional burden during feeding challenges, whereas personalization fit was associated with cognitive empowerment, which in turn was associated with mothers' self-reported capacity to critically evaluate and adapt AI advice.

These indirect associations may reflect potentially important constructs by which AI engagement is associated with perceived nutrition-oriented feeding practices. Within the data, the perceived value of AI in toddler feeding appeared to relate less to algorithmic sophistication than to perceived trust, contextual fit, and support for maternal judgment. Beyond these associations, and extending past what the present cross-sectional data can establish, the findings may hold tentative implications for clinicians, policymakers, and developers. They may inform future research on, and the eventual design and evaluation of, AI-assisted feeding support, provided such tools are positioned to complement rather than supplant professional nutrition counseling. These implications remain hypotheses for future longitudinal and intervention research rather than evidence-based recommendations. In addition to these quantitative pathways, this study contributes a qualitative typology of AI engagement constructs specific to the toddler-feeding context, providing a conceptual foundation for future research at the intersection of AI, maternal cognition, and child nutrition.

Abstract

Background: Childhood obesity is a global health concern with long-term cardiometabolic and psychosocial consequences. Establishing healthy feeding and lifestyle behaviors from infancy is critical to population health efforts with a life course perspective. Recently, digital health applications have gained traction in reaching out to parents and promoting healthy feeding behaviors.

Objective: The aim of this study was to evaluate the usability and acceptability of the Feeding, Lifestyle, Activity Goals app in providing parents with evidence-based guidance and tailored advice to promote healthier eating behaviors and lifestyle habits among infants.

Methods: We conducted a mixed methods pilot study among parents of infants aged 0 to 24 months recruited from a tertiary maternity and children's hospital in Singapore. Participants used the digital health app for 7 days. Usability was assessed using the validated System Usability Scale (score range 0 - 100, with ≥70 indicating acceptable usability). Acceptability was explored via open-ended questionnaires on satisfaction, relevance, and user experience, with qualitative data analyzed thematically by 2 independent coders to ensure rigor.

Results: A total of 26 parents of infants aged 3 weeks to 23 months completed the study. The app demonstrated good usability, with a mean System Usability Scale score of 71.3 (SD 11.0). Parents valued its role in organizing infant care; promoting self-reflection on parenting practices; and providing personalized, evidence-based recommendations. These benefits were particularly appreciated by first-time parents and those with multiple caregiving responsibilities. Challenges included an unintuitive user interface, high manual data entry burden, and advisory content that was occasionally overly general or text heavy. These insights highlight clear priorities for onward efforts in optimization.

Conclusions: Results of our mixed methods evaluation indicate that our digital health app demonstrated good usability and acceptability among parents of infants. Targeted refinements to the interface, data entry processes, and content delivery are warranted before large-scale evaluation to determine its impact on early-life health behaviors and obesity prevention.

Introduction

Childhood obesity is rising at an alarming rate worldwide. According to the World Health Organization [1], an estimated 35 million children under the age of 5 years are overweight, and the prevalence of children and adolescents with overweight aged 5 to 19 years has risen significantly from 8% in 1990 to 20% in 2022. This surge in childhood obesity not only results in health-related comorbidities such as metabolic syndrome and orthopedic issues but also significantly affects children's psychological well-being, body image, and overall quality of life [2]. In the long term, these children also have a moderate risk of obesity persisting into adulthood [3], along with its cardiovascular complications.

Numerous studies have shown that children's eating habits [4] and food preferences [5] are strongly linked to their body composition, with unhealthy diets and poor feeding practices increasing the risk of childhood obesity. Importantly, these dietary patterns often persist into adulthood as feeding practices established in early life influence future dietary and taste preferences [6,7]. Therefore, timely interventions during early childhood, particularly those aimed at shaping healthy feeding behaviors, are critical for long-term obesity prevention and for promoting sustainable, healthy growth trajectories [8]. Parents play a central role in this process [9]. From infancy, they influence not only the types and amounts of food offered to children but also the emotional and environmental context in which meals take place [10]. As a result, many public health initiatives encourage parents to act as "health promoters" shaping their child's feeding behaviors and long-term food preferences through informed and consistent modeling and support [11,12].

However, providing parents with consistent, evidence-based support remains challenging. Traditional interventions targeting feeding behaviors, such as in-person counseling and motivational interviewing, have shown benefit but are often labor-intensive, time-consuming, and difficult to scale [13]. With the advent of technological advancements, digital interventions such as mobile health (mHealth) apps have gained traction as a means of expanding outreach to parents and providing accessible, around-the-clock support for improving dietary choices and feeding behaviors [11]. For instance, a recent pilot study evaluating a parent-focused mHealth app designed to promote healthy eating behaviors in children found that parents perceived the app as helpful in increasing their nutritional knowledge and awareness of their children's diet [12]. Similar digital interventions in adult populations have also shown promise, with meta-analyses highlighting their effectiveness in managing and preventing obesity [14]. However, despite these benefits, commercially available mHealth apps still lack medical oversight, are not co-designed by stakeholders including health care professionals and end users, and often fall short in providing evidence-based or culturally tailored content [15,16]. These drawbacks limit their effectiveness and credibility, particularly when used as stand-alone tools for behavior change. In addition, given that cultural influences strongly shape feeding practices [17], there is a clear need for digital solutions that are evidence based, medically guided, and culturally sensitive, with the eventual aim of reinforcing good dietary practices and habits in the pediatric population.

To this end, our study team involving a diverse panel of domain experts, including neonatologists, pediatricians, dietitians, speech therapists, physiotherapists, and nurses, developed a digital health app named Feeding, Lifestyle, Activity Goals (FLAGs) to promote healthier eating behaviors and lifestyle habits in infants from birth to the age of 2 years. Its development involved a meticulous process for which the questionnaires and advisory content underwent extensive curation [18]. The tool is grounded in theoretical frameworks such as the capability, opportunity, and motivation–behavior framework, which emphasizes enhancing parents' capabilities through skill-building, while providing opportunities and motivation via a user-friendly app to support behavioral change and promote healthy feeding habits. Overall, FLAGs serves as both an assessment tool and a provider of tailored advice for parents on their infants' feeding practices, sedentary behavior, and physical activity. In this study, we specifically aimed to perform a mixed methods evaluation of the app's usability and acceptability among end users. These findings will inform iterative refinements and subsequent large-scale trials to examine the app's efficacy in effecting behavior change and on anthropometric outcomes.

Methods

Study Design and Setting

We conducted a mixed methods pilot study at KK Women's and Children's Hospital, Singapore, to evaluate the app's usability and acceptability among parents of infants. The study period was from September 2024 to November 2024.

Participants and Recruitment

A purposive sampling strategy was used to recruit eligible parents or primary caregivers of infants aged 0 to 24 months during outpatient clinic visits. Sampling sought to capture diversity in parental age, ethnicity, and caregiving experience to obtain a broad range of perspectives on usability and acceptability.

Our inclusion criteria were infants aged 0 to 24 months as well as parents' ability to understand a basic level of English in view of the fact that all the content within the app and the feedback instruments used was in English. Meanwhile, our exclusion criteria were any infants with congenital abnormalities and physical or neurodevelopmental disabilities that may interfere with app use or who may have unique feeding requirements.

Ethical Considerations

Ethics approval was obtained from the SingHealth Centralised Institutional Review Board, Singapore (reference 2024/3224). The study was conducted in accordance with the principles of the Declaration of Helsinki and adhered to all applicable local regulatory requirements. All participants received a verbal and written explanation of the study and provided written informed consent before enrollment. Upon successful completion of the study, participants received reimbursement of SG $20 (approximately US $15). Each participant was assigned an

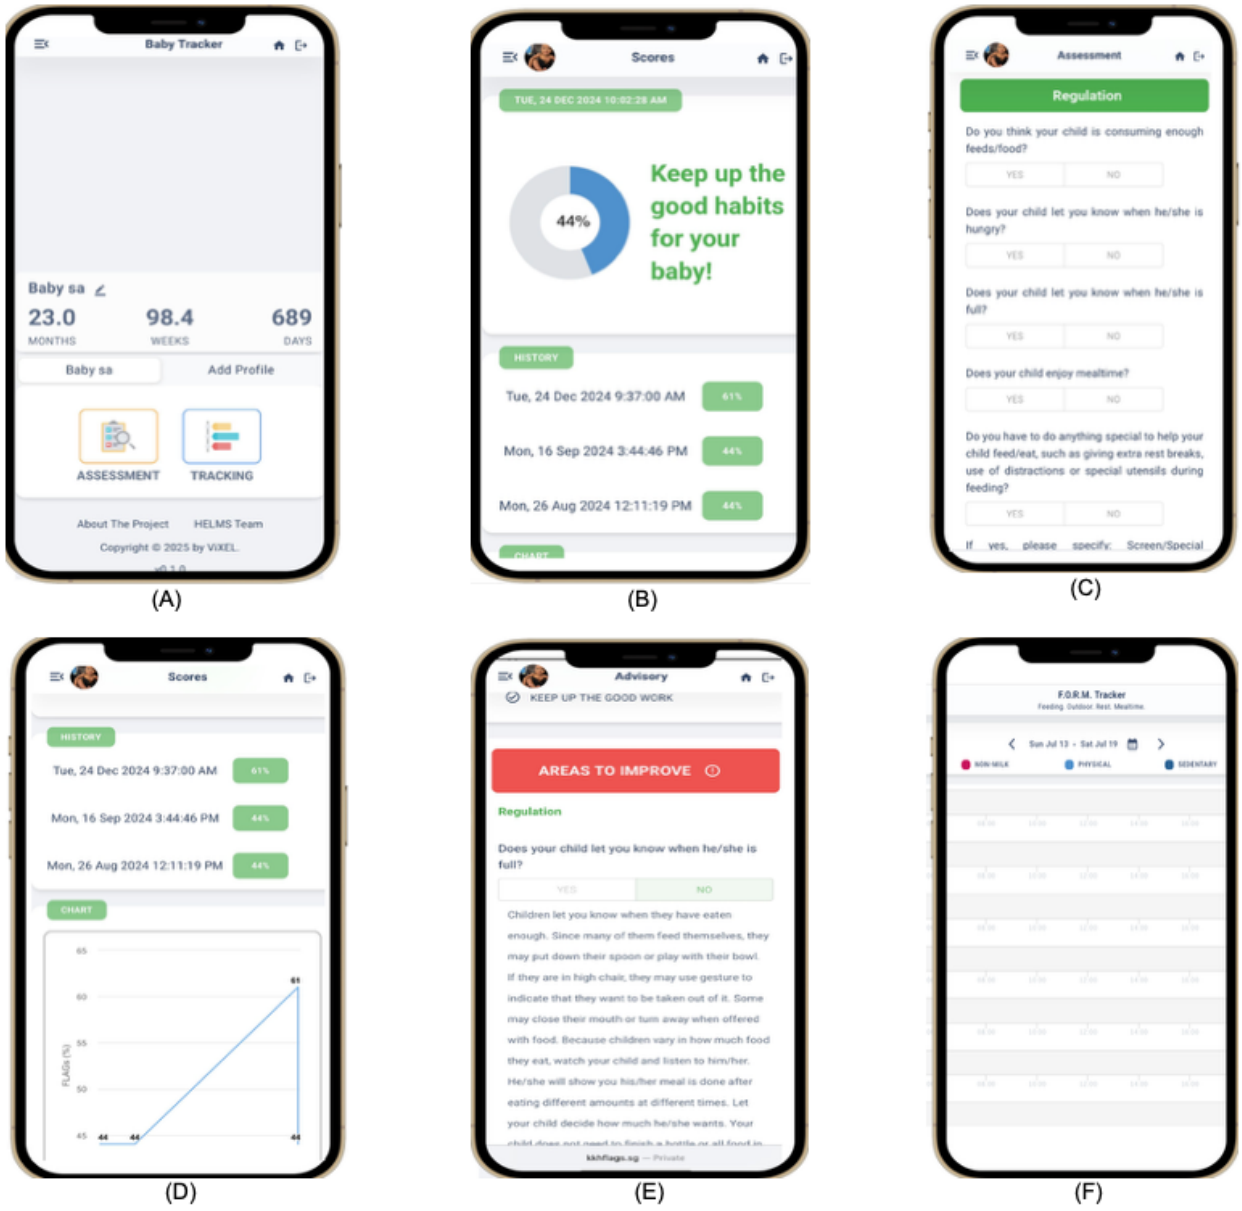
XSL•FO
RenderX

anonymized study ID; all collected data were encrypted and stored on a secure, password-protected server accessible only to the study team.

Study Procedures

At baseline, we collected parental and infant demographic data, including age, sex, ethnicity, and gestational age at birth. Infant anthropometry was measured using the Seca 210 mobile measuring mat for recumbent length and Seca 334 weighing scale for weight, and BMI-for-age was calculated as weight divided by height squared (kg/m^2). After recruitment, participants underwent a cognitive walk-through via both verbal explanation and a pictorial guide demonstrating the user interface with key features. They were then provided with installation instructions and granted full access to the app for a 7-day trial. In terms of the duration for this trial, a study by Steele et al [19] in Durham, North Carolina, United States, found that brief intensive internet-delivered cognitive behavioral therapy on social anxiety for 7 days was feasible, with low premature dropout rates. Similarly, a 7-day mobile tracking study [20] on sleep in students found that there was sufficient variance in terms of the data provided. Hence, the decision was made to use a 7-day trial.

Participants were encouraged to explore all functions without a prescribed recording schedule to reflect real-world use. Intake data (feeding, activity, and growth) could be logged ad libitum. Following the 7-day trial, participants promptly provided an interview time. During the online video interview, the System Usability Scale (SUS) questionnaire was administered via screen sharing, and responses were recorded accordingly. Subsequently, participants continued in a semistructured interview format with open-ended questions. Interviews were audio recorded with consent and transcribed verbatim. All interviews were completed within 1 month from the time of recruitment.



FLAGs Digital Health App

To address the need for an optimized, medically guided feeding intervention, our team at KK Women's and Children's Hospital first developed a validated assessment instrument—the FLAGs digital health app—to evaluate infant feeding and lifestyle behaviors. The team comprised neonatologists, pediatricians, obstetricians, and dietitians. Psychometric evaluation of the app revealed strong clarity, relevance, and simplicity. Overall, the Cronbach α was 0.71, and the intraclass correlation coefficient of 0.861 ($P<.001$) indicated statistically significant test-retest reliability, supporting the instrument's validity and reliability [18]. Subsequently, the instrument was converted into a digital health app that enables caregivers to log and track their infants' dietary intake, physical activity, and growth parameters, generating visual summaries (graphs and trends) and personalized, evidence-based recommendations. Another framework that provided a foundation for our digital health app was the theory of planned behavior [21]. This theory looks at the close relationship between infant feeding practices and parents' behaviors, which are shaped by subjective norms and perceived control.

The app consists of several user modules, beginning with a secure log-in and profile setup that personalizes questions based on the child's age and feeding stage. The assessment module comprises 11 to 18 items categorized into 3 core domains: regulation, which assesses recognition of hunger and satiety cues, feeding responsiveness, and infant self-soothing; weaning, which covers complementary feeding initiation, food texture progression, and parental feeding approaches; and habituation, which evaluates sleep duration, screen exposure, and daily activity routines. Each question is age specific and uses either a binary ("yes" or "no") or categorical (eg, 5 to 30 minutes per meal or ≤1 hour vs >1 hour of screen time) response format. Responses are automatically scored within the app: a healthy, age-appropriate behavior is awarded 1 point, whereas an at-risk or suboptimal response receives 0 points. Domain-specific subscores and an overall FLAGs composite score (0% - 100%) are then computed in real time. Upon scoring, the app instantly generates personalized advisory feedback displayed on the "Advisory" and "Scores" pages, providing parents with clear, actionable recommendations to support healthy feeding and lifestyle practices. The app also features daily and weekly tracking modules that allow users to record milk intake, food consumption, physical activity, sedentary time, and sleep. Input forms are editable for flexibility, with weekly summaries enabling trend visualization over time. The behavioral nudges within the FLAGs app are automatically tailored to the child's age group and corresponding developmental stage. Key interface elements of the intervention are shown in Figure 1.

Screenshots of the Feeding, Lifestyle, Activity Goals (FLAGs) digital health app: (A) main landing page, (B) score display screen, (C) FLAGs questionnaire, (D) trends in feeding and lifestyle scores, (E) tailored parental advisory and recommendations, and (F) daily feed and physical activity log.

Outcomes and Measures

The primary outcome was usability, assessed using the validated 10-item SUS [22] (score range 0 - 100, with ≥70 indicating acceptable usability for digital tools). This was interviewer administered, with a standardized script for each question; no prompts, explanations, or leading cues were provided beyond the original wording of the SUS items, and participants were given time to consider each question and respond accordingly.

The secondary outcome was acceptability, assessed via open-ended, semistructured interviews. Participants were asked the following five questions: (1) “what did you like about the digital health application?” (2) “What did you dislike about the digital health application?” (3) “What features would you like to see retained in the digital health application?” (4) “What features would you like to remove or change in the digital health application?” (5) “Do you have any other comments about the digital health application?” These questions were designed to elicit both positive and negative experiences, feature-specific feedback, and additional suggestions for improvement. An interview guide that includes the SUS and acceptability questionnaire used is provided in Multimedia Appendix 1.

Data Analysis

Quantitative data analysis was conducted using Stata (version 18; StataCorp LLC). Participant demographic and baseline characteristics were tabulated to provide a descriptive overview of the sample. For the SUS, the mean and SD, as well as sample size and frequency, were calculated for each individual item to identify variability in responses and for the total SUS score to assess overall system usability.

XSL•FO
RenderX

To qualitatively analyze user experience of the FLAGs app, all audio recordings of participant interviews were transcribed and analyzed using Microsoft Word. Using the grounded theory approach [23], data analysis involved line-by-line coding, axial coding, and selective coding by 2 independent researchers to generate broad conceptual themes. In the later stage of analysis, all major categories, themes, and subthemes were operationalized. Relationships between themes and subthemes were proposed and substantiated with relevant quotes from participants. To ensure research rigor and trustworthiness of the findings, stringent mechanisms were put in place. These included maintaining an audit trail of research decisions, changes, and data analysis; interresearcher consensus in finalizing themes; and frequent peer debriefing to review interpretations and findings so as to minimize researcher bias [24,25].

Results

Participant Characteristics

A total of 34 participants were recruited and assessed for eligibility for the study. Subsequently, of the 34 assessed participants, 11.8% (4/34) were excluded as they were unable to understand English, which is the working language of the app and survey questionnaires. Eventually, of the remaining 30 participants, 86.7% (26/30) were interviewed as 10% (3/30) were lost to follow-up and 3.3% (1/30) withdrew from the study for personal reasons. Figure 2 shows the flowchart of the included and excluded participants and those who completed the study.

Figure 2. Flowchart of participant selection for the Feeding, Lifestyle, Activity Goals digital health app study.

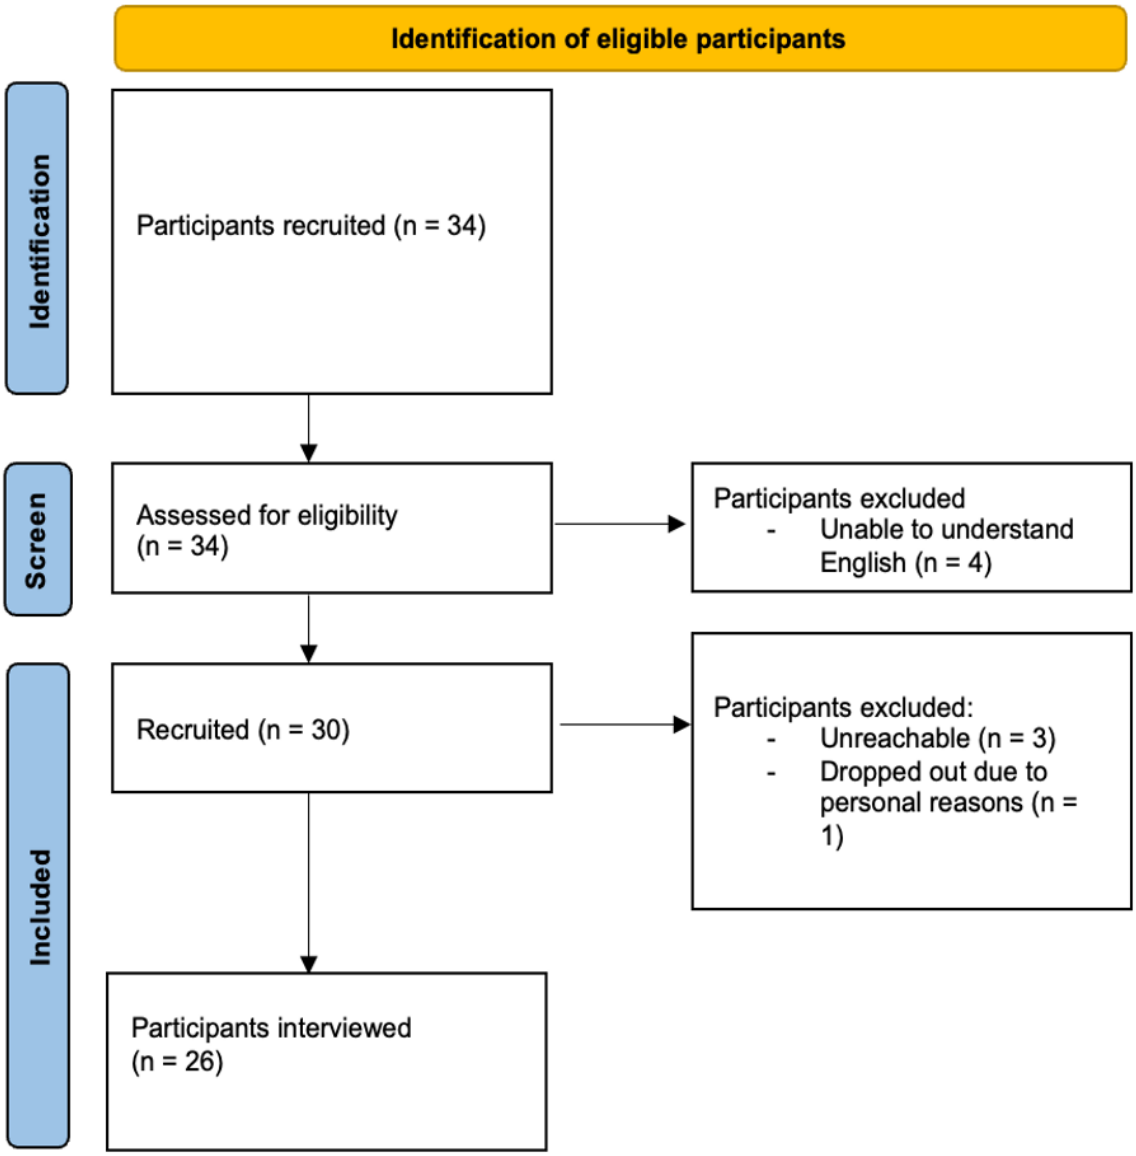

Table 1 describes the baseline characteristics of the parents and their children. Of the 26 parents, 73.1% (19/26) were female, and the mean age was 33.7 (SD 5.2) years. In terms of educational level, most parents were diploma holders (10/26,

XSL•FO
RenderX

38.5%) and degree holders (10/26, 38.5%). Regarding the demographic characteristics of the children, 53.8% (14/26) were males. The mean age was 7.4 (SD 5.0) months, with ages ranging from 3 weeks to 23 months.

Table . Baseline characteristics of the participants (N=26).

Characteristics	Participants
Caregiver's age (y), mean (SD)	33.7 (5.2)
Caregiver's relationship to the child, n (%)	
Mother	19 (73.1)
Father	7 (26.9)
Caregiver's monthly household income, n (%)	
<SGD 10,000 (US $7830.60)	17 (65.4)
≥SGD 10,000 (US $7830.60)	9 (34.6)
Child's age (mo), mean (SD)	7.4 (5.0)
<12, n (%)	18 (69.2)
≥12, n (%)	8 (30.8)
Child's sex, n (%)	
Male	14 (53.8)
Female	12 (46.2)
Child's ethnicity, n (%)	
Chinese	13 (50)
Indian	9 (34.6)
Malay	4 (15.4)
Child's gestational age at birth (wk), n (%)	
Full term (≥37)	21 (80.8)
Preterm (<37)	5 (19.2)

Usability

Table 2 shows the proportion of responses and the mean scores for questions from the SUS. Scores for each item on the questionnaire range from 1 to 10, with a maximum possible score of 100. The mean SUS score for our FLAGs app was 71.3 (SD 11.0). Half (14/26, 53.8%) of the participants reported that they would use this digital intervention frequently to improve their children's feeding behavior and nutritional choices. In addition, more than two-thirds (19/26, 73.1%) thought that the product was easy to use. Most (21/26, 80.8%) disagreed that they required technical assistance to use the digital intervention. Overall, this reported ease of use of the product appeared to translate into confidence in the implementation of the app into their lifestyles (20/26, 76.9%).

XSL•FO
RenderX

Table . Breakdown of responses to the System Usability Scale (SUS) questionnaire. The SUS score was calculated based on processes originally developed by Brooke [26] (N=26).

	Score, mean (SD)	Disagree, n (%)	Neutral, n (%)	Agree, n (%)
I think that I would like to use this product frequently.	3.4 (1.2)	6 (23.1)	6 (23.1)	14 (53.8)
I found the product unnecessarily complex.	2.6 (1.1)	17 (65.4)	2 (7.7)	7 (26.9)
I thought the product was easy to use.	4 (1.0)	3 (11.5)	4 (15.4)	19 (73.1)
I think that I would need the support of a technical person to be able to use this product.	1.7 (1.0)	21 (80.8)	3 (11.5)	2 (7.7)
I found the various functions in the product were well integrated.	3.6 (0.9)	4 (15.4)	7 (26.9)	15 (57.7)
I thought there was too much inconsistency in this product.	2.0 (0.7)	7 (26.9)	12 (46.2)	7 (26.9)
I imagine that most people would learn to use this product very quickly.	4.2 (0.9)	1 (3.8)	3 (11.5)	22 (84.6)
I found the product very awkward to use.	2.3 (1.0)	17 (65.4)	6 (23.1)	3 (11.5)
I felt very confident using the product.	4.0 (0.8)	1 (3.8)	5 (19.2)	20 (76.9)
I needed to learn a lot of things before I could get going with this product.	2.2 (1.1)	15 (57.7)	8 (30.8)	3 (11.5)

Acceptability

Overview

The acceptability of the FLAGs app was evaluated through qualitative responses from parents regarding their experiences using the digital tool. These responses were categorized into three overarching themes: (1) positive experiences, (2) challenges encountered, and (3) desired features not currently available. Each theme was further broken down into subthemes reflecting specific aspects of the user experience.

Theme 1: Positive Experiences

This theme highlights the perceived benefits of using the FLAGs app, particularly in enhancing the organization of infant care, improving self-awareness and reflection, and fostering parental empowerment. These strengths suggest strong acceptability of the app among parents and caregivers.

Better Organization of Infants' Care

Parents reported that the app supported better management of their infants' daily routines, particularly regarding feeding and sleeping schedules. This benefit was especially prominent among first-time parents or those with multiple responsibilities:

> *The tracker is very useful, and it helps me to see if my baby had fed or not. I don't have to keep recalling when I feed my baby.* [P7]

> *I'm more aware of the baby and I am very interested to log the feeding habits of baby into the app.* [P6]

Greater Clarity on Parenting Practices

The app's personalized assessments and data visualization features allowed users to reflect on their parenting practices and identify areas for improvement. This was facilitated through automated, tailored feedback based on questionnaire responses:

> *Overall, the app is good to use but there are still more apps like this, but this is special because [it has] the advisory based on what you answer in the questionnaire.* [P1]

The assessment also allowed parents to reflect and self-evaluate while visualizing their progress over time through graphics such as bar graphs and charts:

> *The advisory is very helpful so it can show me roughly where I stand in terms of what to improve as a parent for my baby.* [P7]

Empowerment in Infant Care

Parents expressed that the app supported evidence-based parenting while reducing their dependence on health care providers for day-to-day concerns:

> *I like the fact that this app is like a guide. Like for example, they will tell you what is good and what is*

XSL•FO
RenderX

> *not good. For example, I can know how long of a nap is good for my baby.* [P5]
>
> *As (a) first-time parent I feel like I don't need to seek for doctors help or ask doctors on a regular basis.* [P11]

Other Strengths

Other less common but pertinent strengths included the fact that the app was supported by KK Women's and Children's Hospital, a public tertiary maternal-child hospital, thus improving parental trust:

> *Maybe there are more apps, but this is maybe more trustworthy because it's from [a] hospital.* [P8]

Others appreciated the delivery of behavioral nudges via WhatsApp:

> *I quite like the concept of this whole thing [the app] including the nudges which is a fresh idea to be sent [through] WhatsApp.* [P9]

Theme 2: Challenges Encountered

Despite the positive experiences, several challenges with the app were identified, primarily related to usability—including operational issues, the complexity of the tracking process, and the relevance of the content—which helped further contextualize the SUS score.

Further Improvements Required in the User Interface

Many users described the app as being visually unrefined and having navigation issues. Issues ranged from log-in troubles to technical bugs:

> *For the login page, I had to keep logging in for the 7 days and I find it a bit troublesome and time consuming and there is no password view option, so I took very long to login to the app initially.* [P9]
>
> *When I did the assessment, I cannot look back at it after I complete it. Like there is no record of my assessment. When I did it one time, I cannot see the output of like the results of it. I briefly saw the results but when I tried to find it again, it is disappeared.* [P8]

Cumbersome Tracking Process

Users expressed difficulty in consistently inputting feeding and sleep data, especially when multitasking or without prompts from the app:

> *Since I do not really know the exact timing of the baby sleeping and feeding time I can't really be consistent with the app. I just try my best when I'm at home to try login. Also, when I'm helping to take care of the baby I try to put away my phone from sight, so the baby doesn't try to take it. So, I can use only based on my memory.* [P18]

This was especially relevant as the app did not auto-suggest entries based on previous entries, thereby increasing the cognitive load on parents:

> *I feel like the macro of the food is necessary information for medical side but for me I feel stressed to put in so many things. [The app they were using previously] is better comparatively because I can choose the food from previous options I have keyed in the app.* [P11]

Wordy Content

The app's advisory section was seen as too text heavy, with users preferring more concise and targeted information:

> *I think I find it very wordy generally. There are more things to input, and the advisory is also very wordy. I think bite sized information is preferred by most of the parents because everything is fast moving now. And maybe if user can choose like a certain topic that they are more interested then, it can give a full explanation. Like if I'm worried about my baby's sleep then I can click on the sleep advisory for more details.* [P9]

Furthermore, some feedback suggested that the assessments could be misleading or stressful due to a lack of sufficient personalization:

> *"Your child doesn't need any distraction or effort when feeding." That was not true for our child who really did not enjoy mealtimes despite countless efforts. [The recommendations] should be stated clearly that it may not always be the case.* [P27]

Theme 3: Desired Features Not Currently Available

Several participants proposed enhancements to improve the app's usability and collaborative potential. These fell into 3 subcategories: shared access, simplified input methods, and better access to historical data.

Shared Access for Different Caregivers

Users expressed a desire for options for multiple caregivers, emphasizing the importance of collaborative tracking. Suggestions included a shared account for caregivers and ease of log-in for multiple users:

> *And it will provide better communication between caretakers.* [P12]
>
> *I try to login using my husband phone also so I use only evening time. So I could not every time login the food and sleep. I just put in what I remember.* [P17]

Simplified Input Methods

Participants expressed a need for more intuitive input methods, such as preset options, visual timers, and icons to reduce manual entry burden:

> *As for the inputting the details of the data, it could be easier. To be honest, because I am using another app, I haven't been using it regularly also but whenever I get the time I use it. So even for that app when it's easier to type the data, I don't seem to use it often, so this app I don't see myself being very frequently using it. In terms of icon, there can be a new icon for breast feeding to show like breast milk*

XSL•FO
RenderX

> *vs formula. It's like for easier navigation so I don't have to type out what type of milk I'm feeding all the time. Inputting the timing is also quite tedious, instead they can have like a stopwatch like the baby time app I'm using now. There is an instant update of the current time the mummy Is feeding.* [P21]

Photo uploads were another frequently requested feature, especially for food tracking and medical documentation:

> *It's easier to upload a picture and will be easier for your reference as well. And when I want to show let's say to my doctor also, he can get the idea of how the food actually looks.* [P12]
>
> *Good to also include option to upload photos...i.e. stool consistency and color.* [P22]

Archiving and Access to Past Assessments

A common request was for a feature that allows users to revisit previous assessments and advisories. This allows for longitudinal tracking and review of prior advisories and scores:

> *I want to look back at the advisories and maybe have like an archive of previous advisories and assessment scores so that we can see the improvement and refer easily to the advice.* [P6]

Discussion

This study evaluated the usability and acceptability of an mHealth app designed to support parents of infants aged 3 weeks to 23 months with evidence-based resources and personalized advice on feeding, physical activity, and growth. Overall, the digital health app demonstrated good usability, as evidenced by the mean SUS score. This places FLAGs in a range consistent with functional but improvable health technology [19]. In terms of acceptability, parents emphasized several positive aspects of the app, suggesting that it was generally well accepted within the study population. In particular, parents valued the structured organization of caregiving tasks, the ability to visualize progress, and the provision of evidence-based feedback in real time. These features created a sense of confidence and empowerment, particularly for first-time parents and for those balancing multiple caregiving roles. Many participants expressed that FLAGs offered reassurance and guidance that might otherwise be unavailable between clinical encounters, reflecting both the app's acceptability and its potential to bridge gaps in routine parenting support. Challenges, particularly on the usability front, still remain and will guide subsequent work to improve the app's usability. For example, the interface was perceived to be occasionally unintuitive, and data entry, while comprehensive, was regarded as burdensome and overly manual, limiting sustained engagement in day-to-day use. Advisory content was sometimes experienced as verbose, which risked diluting its impact and reducing its immediate applicability. Frequently suggested improvements included the ability to share access across multiple caregivers, streamlined logging features such as photo uploads and visual timers, and the capacity to archive and retrieve past assessments. Taken together, these findings suggest that FLAGs has achieved sufficient baseline usability and acceptability to justify further development, with a road map for further iteration.

When considered in relation to the wider literature, our findings reinforce both the promise and the challenges of parent-facing digital health interventions in early childhood, consistent with evidence from preschool interventions. For example, the MINISTOP (Mobile-Based Intervention Intended to Stop Obesity in Preschoolers) trial demonstrated improvements in composite diet and activity behaviors among children aged 4 years, underscoring the feasibility of app-based parent engagement [13]. Similarly, the Food4toddlers study revealed that parental access to the Food4toddlers website improved the frequency of intake of vegetables among toddlers immediately after the 6-month intervention period ended [27]. Building on these works, the Early Food for Future Health trial noted that an internet-based tool for parents of children aged between 6 and 12 months was appropriate and feasible to propagate information on healthy infant feeding to Norwegian mothers, leading to an increase in young children's daily vegetable and fruit intake [28]. More generally, meta-analyses confirm that digital health interventions can promote healthier nutrition behaviors in children and families [11] and are effective in weight management among adults [14]. At the same time, reviews of pediatric nutrition apps have raised concerns regarding lack of clinical input, inadequate behavior change mechanisms, and poor usability [15,16]. A scoping review on child health promotion apps by Blakeslee et al [29] similarly acknowledged the importance for apps to be grounded in transparent theoretical frameworks and that content should be tailored to include intuitive and adaptive features—all challenges mirrored by parents' feedback in our study calling for clearer, more targeted content and more usable logging. These findings highlight a key point: effectiveness is unlikely to be determined by the presence of digital content alone but rather by the integration of evidence-based content, clinical oversight, and user-centered design.

Our findings carry several implications for future iterations of FLAGs and design of similar interventions. First, minimizing interaction burden is likely to be critical for engagement. Parents consistently requested features that reduce repetitive manual data entry, such as preset options for routine inputs, auto-suggestions, and smart defaults [20,21]. Incorporating semipassive data capture where feasible could further enhance efficiency and lower friction. Second, personalization emerged as a strong driver of acceptability. Tailoring advisory content to infant age, feeding stage, and parent preferences and delivering messages in concise, layered formats would likely improve both perceived relevance and usability [29,30]. Third, supporting the broader caregiving ecosystem will be essential. Parents emphasized the need for shared caregiver accounts, secure photo uploads, and archival functions that support continuity of care, reflecting the reality that infant caregiving is rarely the responsibility of a single individual. Embedding FLAGs into routine pediatric follow-up visits such as growth monitoring or immunization appointments may normalize its use and provide opportunities for light-touch reinforcement by clinicians without imposing additional workload. Finally, equity considerations must be foregrounded in subsequent iterations,

XSL•FO
RenderX

including the development of multilingual content, culturally appropriate guidance, offline-tolerant features, and accessible visual design.

Moving forward, our study team intends to evaluate the efficacy of the FLAGs app through a randomized controlled trial (NCT06457750) in improving anthropometric outcomes and establish its broader behavioral and health impacts [30]. This prospective interventional study aims to examine changes in infant feeding practices; mealtime routines; and anthropometric outcomes such as weight-for-length, BMI, and adiposity. Incorporating validated behavioral scales such as the Baby Eating Behavior Questionnaire and Children's Eating Behavior Questionnaire [31] alongside growth metrics would provide a robust assessment of efficacy. Equally important will be the systematic evaluation of mediators (such as engagement dose and message exposure) and moderators (such as parity and baseline feeding difficulties). Use analytics, including log-in frequency, feature taps, and completion of advisories, should be analyzed a priori to explore "dose-response relationships" and fidelity of engagement [20,21,30]. Such an approach would advance understanding of not only whether the app works but also how it works and for whom it is most effective.

This study has several strengths. The FLAGs digital health app was developed through a clinically informed, framework-based process integrating evidence-based recommendations with input from health care professionals. The mixed methods design is a comprehensive process of evaluation that allowed for triangulation of quantitative and qualitative insights, enriching interpretation and ensuring that usability ratings were contextualized by lived experiences. Rigorous qualitative analysis procedures, including independent coding, consensus discussions, and audit trails, enhanced the trustworthiness of the findings.

Nevertheless, several limitations should be acknowledged. The sample was small, clinic based, and restricted to English-speaking participants, which limits generalizability. The 7-day evaluation period was limited in duration and did not permit the assessment of long-term engagement or sustained behavioral effects. Outcomes relied primarily on self-report, introducing potential recall and social desirability biases, whereas the clinic-based recruitment may have contributed to selection bias. These constraints are typical of a pilot study but must be addressed in future work. Larger and more diverse samples; extended follow-up; and incorporation of objective measures, including food photo diaries and automated tracking of physical activity, will be useful in validating these findings and evaluating real-world impact.

In conclusion, our pilot study showed that FLAGs, a medically guided digital health app, was deemed to be usable and acceptable by target end users, providing structured, evidence-based support for infant feeding and lifestyle practices while identifying areas for refinement such as data entry, personalization, and multicaregiver access. With further system and interface optimization, as well as robust evaluation of its efficacy in a subsequent interventional study, our tool has potential as a scalable strategy to promote healthy routines in early life and support obesity prevention.

Acknowledgments

The authors are grateful to the KK Women's and Children's Hospital clinical and administrative teams for their assistance throughout the recruitment, data collection, and implementation phases of the prospective randomized controlled trial.

Funding

This study was funded by the SingHealth Duke-NUS Academic Medicine Research Grant initiative (financial year 2024; grant AM/TP081/2024 [SRDUKAMR2481]).

Data Availability

All data generated or analyzed during this study are included in this published article and its supplementary information files.

Authors' Contributions

DC and SLL conceptualized the study. SJ conducted data collection, patient interviews, and all statistical analyses. MA, NT, and DC wrote the manuscript. CWK, CO, SLL, FY, CMC, and KYJC provided critical revisions to the manuscript. All authors contributed to manuscript refinement and approved the final version.

Conflicts of Interest

None declared.

Abstract

Background: Research indicates that social media platforms play an important role in disseminating health information. Mothers, in particular, frequently seek guidance on child health through digital resources. Given the growing demand for health-related content, it is necessary to understand how these tools contribute to maternal health education, especially regarding the ability to interpret and apply health information.

Objective: This study aims to investigate how WhatsApp influences the health education processes of mothers, as well as to identify the interests and competencies related to infant oral health among mothers participating in a maternal and child cohort.

Methods: This was a qualitative, exploratory study grounded in the Bardin content analysis framework. Text messages exchanged between mothers and health professionals in a WhatsApp group linked to the Curitiba Maternal and Child Health Cohort (COOSMIC) were analyzed, referring to the years 2020 and 2021.

Results: The corpus was composed of 36 dialogues: 28 concerning infant oral health and 8 regarding the group's impact. The recording units were categorized by themes and interpreted according to emerging core meanings. We identified 2 main themes: eruption of primary teeth (mentioned 12 times) and bruxism in children (mentioned 5 times). Furthermore, in the topic related to the group's impact, we observed a pattern among participants in recognizing the group as a source of support, guidance, and mutual help, highlighting the role of professionals and peer-to-peer exchanges in overcoming doubts and insecurities. Mothers demonstrated an active search for information and collaborative interaction with health professionals, establishing WhatsApp as a support and education network. Competencies linked to oral health literacy ranged from autonomy, empowerment, and security to insecurity, misinformation, and knowledge limitations regarding infant oral health information.

Conclusions: WhatsApp proved to be a relevant tool for accessing information and guidance on infant oral health, favoring mutual support and communication among peers and professionals. The competencies and limitations identified in the mothers' oral health literacy highlight the importance of professionally mediated educational strategies aimed at improving the quality of information and promoting autonomy in infant care.

KEYWORDS

health literacy; HL; health education; digital health; social media; WhatsApp; mobile health; mHealth; oral health; oral health literacy; child health; maternal and child health.

Introduction

Oral health constitutes an essential dimension of general health, as the oral cavity is directly related to quality of life [1]. From a broader perspective, health involves an individual's living conditions and interactions with the environment, which are related to various social determinants [2]. In this context, education plays a prominent role, as it promotes the development of skills and competencies that contribute to quality of life. Thus, it is considered a prerequisite for health [3].

Among these skills, health literacy (HL) stands out, referring to the capacity to interpret, comprehend, and apply health

XSL•FO
RenderX

information [4,5]. When this concept is applied to child health, maternal HL becomes especially relevant, since mothers play a fundamental role in the life and health of their children, directly influencing the formation of good habits [1]. Evidence indicates that children of mothers with higher oral HL have lower rates of dental caries [6], while low levels of oral HL negatively impact children's oral health [7].

Research indicates that social media can play an important role in the dissemination of health information [8]. The active search for health-related content through digital resources has frequently been used by mothers interested in obtaining guidance on child care [9]. Furthermore, these resources offer connection spaces [10] that are specifically present in the maternal routine, providing emotional support and promoting the exchange of experiences between mothers [11,12].

With the growing use of social media by mothers seeking information about their children's health, it becomes necessary to understand how these digital tools contribute to health education, especially concerning the maternal capacity to interpret and apply reliable information. Therefore, this study aims to investigate how WhatsApp (Meta Platforms, Inc) influences the health education processes of mothers, focusing on child health. Furthermore, it seeks to characterize interests in infant oral health, analyze the questions raised, and identify competencies related to infant oral HL within this population.

Methods

Study Design

This study is nested within a cohort of pregnant women, mothers, and their children included in the Curitiba Maternal and Child Health Cohort (COOSMIC), conducted by the Pontifical Catholic University of Paraná (PUCPR), in partnership with the Municipal Health Secretariat of Curitiba [13]. The cohort population includes pregnant women at any gestational stage, aged 16 years or older, residing in Curitiba and receiving care through the "Rede Mãe Curitibana" health network. Participants are followed from pregnancy until the child reaches 2 years of age. The cohort sample consists of 1046 participants, with a mean age of 27.95 years.

This is a qualitative, exploratory study design based on the analysis of secondary data derived from text messages within a WhatsApp group. WhatsApp is a real-time messaging platform that allows for text-based communication and the exchange of various media formats, including photos, videos, documents, and location data [14]. This group was created by the cohort to provide maternal and child health guidance to participants, with an average of 85 members, including mothers and the health care professional (HP) team.

Data Source and Selection Criteria

Data were collected by exporting the WhatsApp group conversations to a text file, which exclusively contained text-based interactions between participating mothers and HPs. The selection of messages was conducted through manual reading, allowing for a comprehensive evaluation of the content shared in the group and ensuring that no relevant themes were missed. Additionally, the search function for specific terms (eg, tooth, mouth, and pain) within the text file was used to complement the manual reading. Only messages addressing doubts related to infant oral health were selected. Messages that did not specifically address this theme were excluded, ensuring that the corpus remained focused on the research's central topic. In addition to this criterion, only data referring to the years 2020 and 2021 were analyzed.

Data Analysis

Data interpretation was conducted using the content analysis method, as proposed by Bardin [15]. Through an exhaustive reading of the material, core meanings related to the investigated topic were identified. Initially, all dialogues were organized in a spreadsheet, where each row contained a question and its corresponding responses, preserving the original interaction flow. The material was reviewed repeatedly to identify recurring patterns in the mothers' questions. Based on these patterns, dialogues addressing similar themes were grouped, allowing thematic categories to emerge inductively from the data. These categories subsequently served as the coding framework for data organization. The final count of dialogues was performed manually after the complete tabulation of all interactions. The coding and thematic categorization process was performed by the primary researcher (NGV) and subsequently reviewed and validated by a senior supervisor (RIW). Any disagreements or uncertainties regarding the definitions of the categories were resolved through consensus meetings between the researcher and the supervisor.

Data collected from the WhatsApp group were organized based on the doubts presented by the mothers. Each dialogue was defined as a single doubt (question), accompanied by one or more responses or interactions from other participants and HPs. Accordingly, dialogues were counted based on each new doubt sent to the group. A single mother could initiate more than one dialogue throughout the analyzed period; thus, the individual participant did not determine the number of dialogues. Cases where a question received no response were also recorded as initiated dialogues, even without subsequent interaction. In addition to dialogues related to infant oral health, a second thematic axis regarding "valuing the group as a support space" was analyzed. In these instances, dialogues were defined by spontaneous messages containing feedback from mothers about their experience in the group.

To facilitate visualization, consecutive messages sent by the same participant within a single dialogue were transcribed on a single line, separated by a forward slash (/). The dialogues were initially analyzed in Portuguese, maintaining the original spelling and informal language to preserve the authenticity of the interactions. For the purposes of this publication, the dialogues were translated into English. This process involved linguistic adaptations designed to ensure clarity and comprehension for the audience while carefully maintaining the informal tone and original intent of the participants' messages.

For the analysis, a standardized nomenclature was adopted to identify participants. Mothers who initiated dialogues with questions or doubts were identified as "Mother A," while those who participated in the interactions by responding were

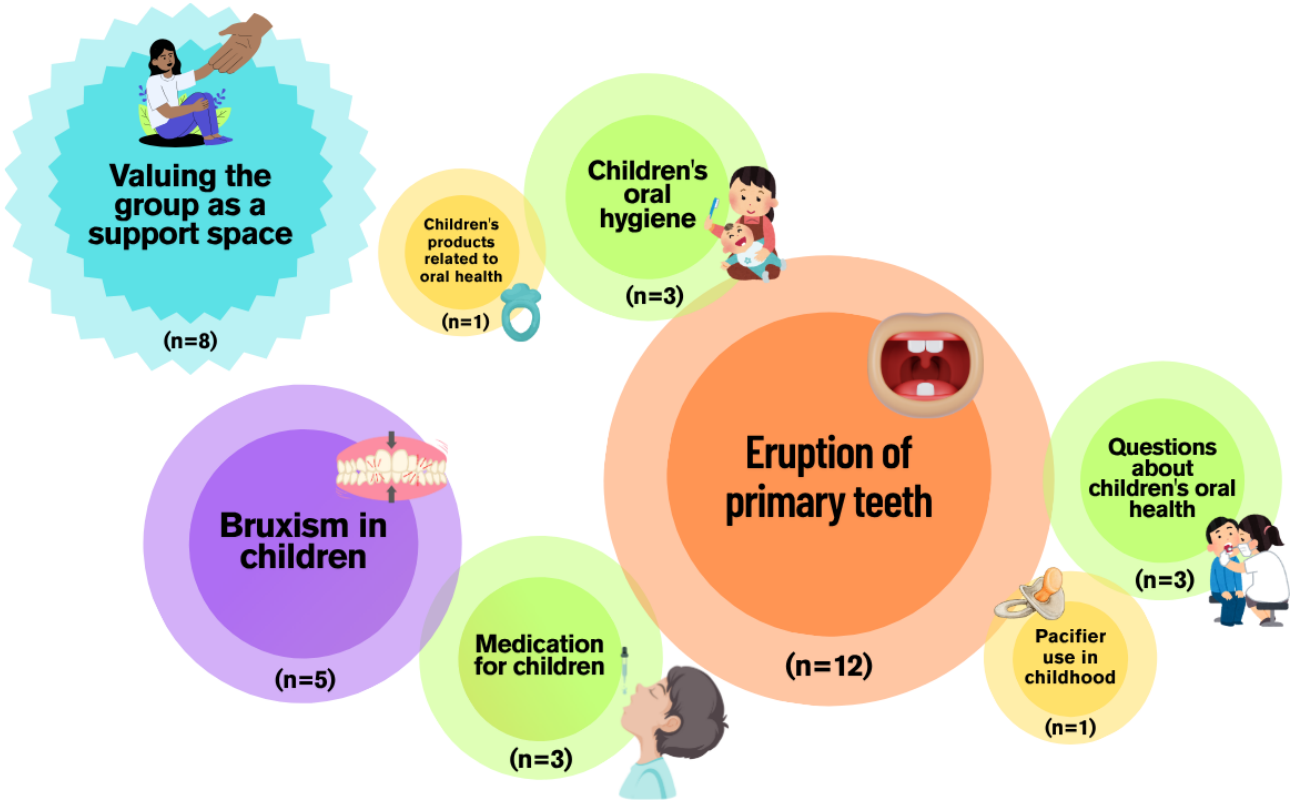
XSL•FO
RenderX

identified as “Mother B.” Responses from the HPs linked to the project were identified as “HP”. In addition to this classification, each participant was assigned a sequential number corresponding to the chronological order of their first intervention in the group. This numerical identification was maintained consistently throughout the entire analysis, regardless of whether the participant initiated new dialogues or interacted in dialogues started by others.

The use of this nomenclature and sequential numbering was adopted to preserve the identity of the participants, protecting personal information such as names and phone numbers. Beyond ensuring data confidentiality, this strategy facilitated the organization and visualization of the dialogues during the analytical process. All identifiers were removed, and quotes were deidentified before analysis to ensure the protection of participant information.

Ethical Considerations

The COOSMIC project was submitted to and approved by the Research Ethics Committees of the PUCPR (approval numbers 4.819.028 and 2.672.385), and the Municipal Health Secretariat of Curitiba (approval number 4.859.861). The current analysis used secondary data from the COOSMIC cohort. At the time of inclusion in the cohort, participants provided informed consent authorizing the collection, storage, and future use of the data for research purposes. All data extracted from the WhatsApp interactions were completely anonymized before analysis and were used with authorization from the COOSMIC coordination team.



Results

Principal Findings

In the coding stage for the theme “infant oral health,” conducted in a Microsoft Excel spreadsheet, the selected material was reorganized and categorized, giving rise to the following themes: eruption of primary teeth, medication for children, bruxism in children, children’s oral hygiene, pacifier use in childhood, children’s products related to oral health, and questions about children’s oral health. Additionally, in a second spreadsheet, dialogues referring to valuing the group as a support space were arranged, in which spontaneous reports from participants praising the team and the group’s operation were observed. After defining the analysis corpus, the data were organized in a Microsoft Excel spreadsheet, totaling 36 dialogues: 28 related to oral health and 8 to the group’s impact.

The most recurrent themes related to “infant oral health” were eruption of primary teeth (mentioned 12 times) and bruxism in children (mentioned 5 times). Additionally, “valuing the group as a support space” was mentioned 8 times. The frequency of mentions of each theme by the participants is represented in Figure 1.

Figure 1. Frequency of themes related to infant oral health. Representation of themes, where the size and color of the circles vary according to the frequency with which each theme was mentioned in the dialogues. Larger circles indicate higher frequency of the theme. Colors correspond to the number of mentions: orange (n=12), blue (n=8), purple (n=5), green (n=3), and yellow (n=1). The number in parentheses (n) indicates the total number of times each theme was cited. The circle with serrated edges represents a theme not directly related to infant oral health and is shown in a distinct format, unlike the other circles, which represent health-related content.

XSL•FO
RenderX

From these data, it was possible to identify the most recurrent themes in the dialogues, as well as the frequency with which they were mentioned by the participants.

Analysis of the Identified Categories

Based on this information, the second stage of the research proceeded, aiming to deeply comprehend the core meanings generated by the mothers regarding the themes discussed.

Eruption of Primary Teeth

Dialogue 1

> ***Mother A1:*** *Any dentist in the group? My daughter is very irritated with her teeth coming in... Besides Camomine [supplement used to relieve teething symptoms] and Nenedent [oral gel for gum pain and itching], what else can I do to relieve it?*
>
> ***HP:*** *You can use Nenedent up to 3 times a day... A teether or something soft, without sharp edges, for her to bite... Another tip is to gently massage...*

The mother's interest in seeking further guidance and her appreciation for professional knowledge are evident. This behavior reflects an active effort to seek information about her child's health in order to expand her knowledge and clarify her doubts.

Dialogue 2

> ***Mother A2:*** *Is anyone's baby having teeth come in?*
>
> ***HP:*** *...An alternative for relief is teethers with gel or water inside... you put it in the refrigerator to chill...*
>
> ***Mother B1:*** *My daughter has one with water... Very good...*

Mother B1's response enriches the dialogue by validating the professional recommendation with her personal experience, illustrating an interaction between mothers and a HP.

Dialogue 3

> ***Mother A3:*** *My baby's tooth came out 3 days before he turned 5 months My first child's came out at 6 months. These children are too early.*
>
> ***Mother B2:***
>
> ***Mother B3:*** *[Name suppressed]'s first tooth came out late at 10 months...*

Beyond resolving doubts, the group functions as a peer support network for mothers, constituting a space where participants share experiences and forge social bonds.

Dialogue 4

> ***Mother A4:*** *How long does it take for a baby's tooth to fully come out? It's been a week that my daughter's has only been tips!*
>
> ***HP:*** *That's normal. The speed varies from child to child. If it has already broken through the gum, it will come in fully soon. Keep monitoring it.*
>
> ***Mother B4:*** *It took a month to be complete... These ones have been two weeks and are coming in very slowly.*
>
> ***Mother B5:*** *It's normal, my 11-month-old baby's is like that too. It takes weeks to come out completely.*

Mother A4's inquiry is addressed with professional guidance regarding individual variations in tooth eruption timing, emphasizing the importance of continuous maternal monitoring. Furthermore, Mothers B4 and B5 contribute by sharing personal accounts of their children's dental development, illustrating the exchange of experiences within the group.

Dialogue 5

> ***Mother A5:*** *My 9-month-old daughter has a fever and is very irritable. Both bottom teeth have come in and I can't identify what it could be... should I take her to the emergency room?*
>
> ***Mother B6:*** *Take her to the doctor.*
>
> ***Mother B7:****Have the top ones come in? If not, it could be that too.*

In this interaction, Mother B7's intervention stands out as she hypothesizes that the child's irritability and discomfort may be associated with the eruption of the upper teeth.

Medication for Children

Dialogue 6

> ***Mother A6:*** *Girls, does anyone here give iron [supplement used to prevent anemia] to their baby? The pediatrician prescribed it, but I see that some children develop rotten teeth when given it. Is it mandatory to give?*
>
> ***Mother B8:****I give it every day. I haven't seen this "rotten tooth" thing, but it was recommended to avoid anemia. I also give Adtil [vitamin A and D supplement]. You have to clean the baby's mouth after giving it, to avoid cavities, according to the baby's dentist.*
>
> ***Mother B9:*** *I give it. And I haven't had any problems with cavities.*
>
> ***Mother B10:*** *I give it and I also give vit. [vitamins] Do I clean the mouth after giving the iron ?*
>
> ***HP:*** *When pediatricians prescribe vitamins (like Ad-til) or minerals (like iron), these serve to supplement the body's nutrient amounts and should be given. Ferrous sulfate can stain teeth.... That's why cleaning the mouth after administering prevents these stains.*

Mother A6 shares her inquiry regarding the necessity of iron supplementation and her concerns about potential dental damage, while Mother B8 recounts her experience and the hygiene instructions provided by a dentist. The dialogue features an intervention by a HP, who clarifies the importance of supplementation and provides guidance on oral hygiene practices to prevent dental staining.

Dialogue 7

> ***Mother A7:*** *...My son's first tooth is showing, so I bought Nenedent [oral gel for gum pain and itching] ointment and applied it for the first time today. I*

XSL•FO
RenderX

would like to know how often I can use it? How many times a day? ... Can it be close to mealtimes?

HP: *...every 6 hours... It can be after, because then the gel stays in contact with the gum longer...*

In this dialogue, Mother A7 seeks detailed instructions regarding the frequency of use and the appropriate timing for applying an oral gel to her child.

Dialogue 8

Mother A8: *...[Name suppressed] is 5 months old and his first tooth broke through the gum today. He's in pain, and very tearful. Can I give him baby paracetamol [acetaminophen]?*

Mother B11: *My experience with my [name suppressed] only the original Camomilina C [herbal medicine used to relieve teething symptoms] worked... even generic didn't help*

HP: *Yes, you can give Tylenol baby [acetaminophen formulated for infants].... Draw up the amount corresponding to his weight in the syringe and... every 8 hours... You can give it for 5 days.*

Mother A8: *I gave paracetamol [acetaminophen], 8 drops directly into his mouth. I did it wrong. Did it really have to be in the syringe??*

In this scenario, Mother A8 seeks guidance regarding the possibility of administering medication to her child and subsequently expresses doubts about the correct method of administration, even after receiving instructions from the HP.

Bruxism in Children

Grouped Dialogues

Similar dialogues were identified among Mothers A9, A10, and A11, who expressed doubts related to their children's habit of grinding their teeth. It was observed that Mothers A9 and A11 received guidance from HPs, while Mother A10 received an answer from another group participant:

Mother A9: *I have a question about my son, is it normal for him to grind his teeth? He is almost 12 months old.*

HP: *It is very common at this age. Take a look at this image I sent!*

Mother A10: *My 7-month-old baby is having teeth come out. But she keeps grinding her teeth, it gives me anxiety*

Mother B12: *My son used to "weirdly move" his jaw... it gave me anxiety..lol I used to tell him "Stop that." But he stopped on his own, never did it again. Oops: "Clicking"*

Mother A11: *My girl is 8 months old and has 4 teeth and grinds her teeth, is it normal? She grinds all the time, it seems like they will break*

HP: *It is very common at this age. Only if the teeth are wearing down too much is a dentist's examination necessary. But up to 2 years of age, the behavior is normal. I sent an image for you to read more about this habit*

In these interactions, mothers share similar experiences and concerns regarding tooth grinding (bruxism) in their children. Consequently, the HP intervenes by providing technical guidance and informative images aimed at addressing the doubts and concerns expressed by the participants.

Dialogue 9

Mother A12: *Guys, my baby started grinding his teeth I keep trying to make him stop. He is 10 months old... He grinds during the day. Not at night*

HP: *This habit is very common at his age. It is only worrying when he hurts himself or his teeth wear down significantly. I will forward an image with more explanations*

Mother B13: *I have bruxism... I have 4 broken teeth... I had several problems, the best thing is early diagnosis and treatment*

In this dialogue, a similar situation is observed with Mother A12, who expresses concern regarding her child's habit of bruxism. In response, the HP provides guidance and seeks to reassure her.

Children's Oral Hygiene

Dialogue 10

Mother A13: *...Is cleaning the baby's mouth after every feeding and meal? I'm doing it after meals... The teeth haven't come in yet, but it's very swollen and almost coming out. I'm cleaning with a cloth and water, I don't know if that's correct. She is seven months old*

Mother B14: *It's recommended to clean with gauze 3 times a day. I only clean when bathing when I give iron [supplement to prevent anemia], after a few minutes. Just so she doesn't get thrush on her tongue. But if there is enough time, you can clean more often*

Mother A13 demonstrates attentiveness to her daughter's oral hygiene by seeking validation of her existing routine. In addition, Mother B14 provides detailed information regarding frequency, materials, and the underlying purposes of the practice, sharing guidance that reflects previous access to technical knowledge on infant oral health.

Pacifier Use in Childhood

Dialogue 11

Mother A14: *...My daughter uses a pacifier, and she turned 6 months old. Do I need to change her pacifier to the 6 to 12 month pacifier?*

Mother B15: *I changed it. My son uses the Mam brand. He used number 1 until six months, then I changed. He accepted it very well. Because Mam pacifiers are all anatomical and always follow the same model, only the size changes... Everything has to evolve as the child evolves... That's why everything is right according to the child's age, right?*

XSL•FO
RenderX

> ***Mother B16:*** *In the beginning, it's strange because of the size... But then you'll see that it fits perfectly.. lol*

In this interaction, Mother B15 provides a detailed personal account of the transition to a new pacifier size and her child's adaptation to the product. Mother B16 complements the dialogue by reporting her own perceptions and initial experiences regarding the size change, thereby illustrating the peer interaction and exchange of experiences among mothers within the group.

Children's Products Related to Oral Health

Dialogue 12

> ***Mother A15:*** *What kind of teether should I buy?*
>
> ***Mother B17:*** *Here I have that little hand from BDA, a butterfly, and a Fisher Price one... There was never a risk of her biting my chest due to confusion. Don't buy a very soft one so there's no confusion during breastfeeding*
>
> ***HP:*** *...those with gel or water inside are great! When the teeth are coming in, you can put them in the refrigerator... The cold relieves local irritation*

In this dialogue, Mother A15 receives information from distinct sources. While Mother B17 shares a personal account, the HP provides guidance based on technical knowledge. This scenario highlights the diversity of information circulating within this digital environment.

Questions About Children's Oral Health

Dialogue 13

> ***Mother A16:*** *My baby has a black spot on his tooth... I don't know what it is. It looks painted, you know? Can anyone tell me if it's normal?...*
>
> ***HP:****Is your child taking any iron medication? We can talk better in private contact.*
>
> ***Mother A16:*** *He takes ferrous sulfate. You can call me*

Mother A16 demonstrates attentiveness and vigilance regarding her child's oral health by reporting observed changes and seeking guidance. In response, the HP seeks to understand the clinical condition in order to provide appropriate guidance. This interaction illustrates how this digital environment facilitates direct communication between the HP and the participant.

Unanswered Questions

During the analysis, doubts raised by participants related to infant oral health were observed; however, these did not have continuity in the dialogue, whether due to a lack of response or a lack of interaction. These records nevertheless highlight mothers' active and recurrent efforts to seek information related to their children's oral health:

> ***Mother A17:****My[name suppressed] is 5 months old, complaining about gum itching and certainly pain too. I've used Camomine C [supplement used to relieve teething symptoms], Nenedent [oral gel for gum pain and itching], Ibuprofen is helping a little... Do you have anything to suggest that helps minimize the discomfort? Please share with me if you have anything to recommend.*
>
> ***Mother A18:*** *I have a question, do I clean after her teeth start to come in or even before?*
>
> ***Mother A19:*** *My 5-month-old baby's teeth are coming in, he is very tearful and not sleeping well. What can I do?*
>
> ***Mother A20:*** *Any tips for when the first tooth breaks through?*
>
> ***Mother A21:*** *How do I perform good oral hygiene if my baby no longer opens his mouth or bites?*
>
> ***Mother A22:*** *Guys, my baby will be 2 months old and doesn't take her hand out of her mouth, she's very irritable*

The excerpt below reveals a series of important elements related to the barriers faced by mothers during the COVID-19 pandemic:

> ***Mother A23:****...I believe the back teeth are coming in (I know because I managed to see, and the gum is super swollen), but she puts her hand in her mouth a lot and complains. Would anyone be able to help me with what to do? Keeping in mind that we are in the COVID-19 pandemic and taking her to the dentist at this moment is complicated. Not to mention that she is autistic, and she has certain rejections.*

The situation described by the mother highlights the difficulties faced in accessing in-person dental care, especially when caring for children with special needs during the health crisis. In this scenario, the group was configured as an accessible support tool given the limitations imposed by the pandemic.

Audiovisual Questions

Dialogue 14

During the analysis, dialogues were observed in which participating mothers used audiovisual media to express their doubts, such as audios, photographs, and videos. However, access to the WhatsApp group interactions was through a text file, making it impossible to view and analyze these other media formats. Therefore, only textual messages were considered. To signal the use of these media, brackets were inserted to indicate the type of media shared by the participant:

> ***Mother A24:****[sent image] It's purple, looks like a sore. He had a fever of almost 40 degrees. The COVID test was negative.*
>
> ***Mother B18:****That tooth is the most painful one, poor thing. There is Nenedent [oral gel for gum pain and itching]... when my children had this discomfort, I applied the ointment and alternated with Novalgin infant solution [dipyrone oral solution for infants]. And I also gave those cold teethers to bite. Check correctly with the pediatrician or pharmacist how much Novalgin you can give, to help with the pain he is feeling.*

XSL•FO
RenderX

HP: *You can use Nenedent or Ad Muc gel [both topical oral gels used to relieve gum discomfort during teething]. Apply about 4 times a day. And you can use an analgesic to help too. The most suitable for babies is Paracetamol [acetaminophen]. 1 drop per kilogram of weight every 8 hours.*

Mother B19: *[link suppressed] Watch this video. Cold things help a lot*

Mother B20: *Mallow tea or mallow compress helps a lot*

Mother B21: *How many months is he? My baby is also 8 and doesn't have any teeth, I'm starting to worry*

Mother B22: *...teeth can take up to 1 year of age to come in. My friend's son had his first ones come in when he turned 1 year old.*

Following Mother A24's question, several interactions took place among the participants, including guidance, suggestions, and the sharing of personal experiences. Mother B19's sharing of a web link illustrates mothers' use of social media to seek health-related information.

Dialogue 15

Mother A25: *[sent audio and image, indicated by the responses as a question regarding the eruption of the baby's dentition]*

Mother B23: *Oh my God. Mine will turn one and it's swollen and still no sign of the first one*

Mother B24: *...I think it's not a rule... Mine's first ones came out at 7 months, one on top and one on the bottom... Then the others came out.*

Mother B25: *Mine had two bottom teeth come out between 5 and 6 months. Now the top is mega swollen for 1 month already and hasn't come out... He turned 10 months*

Based on the audio message and an image shared by Mother A25, the other participants contributed by sharing their personal experiences regarding the timing and sequence of their children's tooth eruption. This type of interaction illustrates the exchange of similar experiences among mothers.

Dialogue 16

Mother A26: *[sent audio, indicated by the responses as a question regarding bruxism in children]*

Mother B26: *It is normal for the baby to grind his teeth. Also because he is discovering himself and because he doesn't have a posterior bite.... But regarding taking the baby to the dentist, this can be done from the first month, to learn how to care...*

In this interaction, Mother B26 responds to the audio message sent by Mother A26, reassuring her about bruxism in children. In addition, she highlights the importance of an early dental consultation, demonstrating confidence and clarity when sharing knowledge about children's oral health.

Dialogue 17

Mother A27: *[sent image] My mother said it's thrush.*

Mother B27: *Does it look like angular cheilitis? Or an aphthous ulcer? Is there only one? Did you notice if she feels pain there?*

Mother B28: *Only one? Does she have a fever?*

Mother B29: *Something she ate that was hot.*

Mother B30: *Thrush. Put gentian violet on it. Put it on a gauze and apply it to the baby's mouth.*

HP: *It could be stomatitis*

In this dialogue, Mother A27's question prompted a series of responses and hypotheses from the other participants, ranging from informal diagnostic suggestions to recommendations for home remedies, such as the use of gentian violet. This interaction highlights the high volume of information and the diversity of guidance shared within the digital environment.

Dialogue 18

Mother A28: *[sent image] Hello, my daughter is 2 months old, and I found this white spot.... Could it be a tooth trying to come out?*

HP: *This spot is likely what we call an Epstein pearl... It is just an alteration in the gum... but it disappears on its own.*

Mother A28: *Thank you.... it's not a tooth! Lol!*

The intervention of the HP was essential in clarifying the mother's concern, promoting her understanding of an unexpected clinical sign. By providing a clear explanation, the HP enabled the mother to correctly interpret the information received, thereby providing reassurance.

Valuing the Group as a Support Space

Reports shared by the mothers reveal the importance attributed to the group as a support space during motherhood. Participants highlight the exchange of experiences and support as differentiators in the maternal experience:

Mother A29: *Welcome[name suppressed], this group is great, we exchange a lot of experience and help each other too*

Mother A30: *This group is truly blessed We are blessed to have the support of professionals 24/7 here*

Mother A31: *Guys, the best thing about being a mother is having this group and this exchange of experiences we have here, it's very good to be able to share our experiences*

Mother A32: *...It's great when you are a first-time mother and have a group like this to clear up doubts...*

Mother A33: *You are angels! The whole team! Thank you very much! ".*

Mother A34: *This team rocks ❣ I am also very grateful to every professional present here... you are fundamental in our lives and our children's lives!...*

Mother A35: *Thank you[name suppressed]! Your call was very important. I felt great*

Mother A36: *Just stopping by to congratulate this Coosmic team!* ❤

XSL•FO
RenderX

Finally, the mothers expressed their appreciation for and satisfaction with the group, highlighting positive aspects such as the opportunity to participate in this space, the possibility of clarifying doubts, the support received, and the strengthening of the support network. In addition, they expressed gratitude for the support provided by the HPs.

Discussion

Principal Findings

This study contributes to the understanding of health education delivered through WhatsApp, highlighting mothers' proactive interest in seeking information about children's oral health. Health guidance provided by HPs through the platform was associated with positive outcomes, facilitating the resolution of mothers' questions while strengthening a peer support network. Our findings further reinforce the idea that the active involvement of HPs is essential to ensure the reliability of oral health information disseminated and shared through digital platforms.

The findings of this study reveal that mothers actively seek information related to their children's oral health through WhatsApp. This behavior reflects their interest in expanding their knowledge and clarifying doubts, as observed in *Dialogue 1* and *Dialogue 11* and in the *Unanswered Questions*. These findings are consistent with the literature, which indicates a growing trend among mothers to use social media as a source of information on child health [9,11].

Beyond information seeking, interactions within the group revealed other relevant behaviors. Among these, the search for opinions, observed in *Dialogue 14*, stands out. Previous studies have also shown that mothers use digital platforms to support decision-making regarding childcare, attributing considerable value to these spaces as sources of information [11]. Another identified aspect was the exchange of experiences, advice, and suggestions among participants. This pattern, observed in *Dialogue 3*, *Dialogue 4*, *Dialogue 14*, and *Dialogue 15*, reinforces collective support and highlights a frequent need for connection and validation of motherhood experiences [11].

In this context, the group extends beyond its role as a space for clarifying doubts and functions as a peer support network, providing an environment in which participants share experiences, recognize common situations, and establish social bonds. This environment is valued by mothers for promoting mutual validation, reassurance, and support, as reported in the findings of this study. Similar findings have been reported in previous studies, which indicate that digital platforms can contribute to mothers' emotional well-being [11] by fostering support, information sharing, and a stronger sense of connection among participants [12].

This study also demonstrates that WhatsApp can be used as a strategy for health promotion. Across several dialogues, HPs play a key role by providing guidance that promotes maternal autonomy. This is illustrated in *Dialogue 4*, in which the mother is advised to monitor her infant's tooth eruption, and in *Dialogue 6* and the *Grouped Dialogues*, where HPs help clarify questions and improve participants' understanding. These findings highlight the potential of social media as a strategic tool for health education [16]. Furthermore, they underscore the importance of professional guidance, as clear explanations enable mothers to correctly understand and independently apply health information, as illustrated in *Dialogue 18*.

In this context, WhatsApp facilitates communication between HPs and mothers. This practice has also been described in previous studies, in which HPs use digital technologies to provide health guidance and information [17,18], reflecting the field of teledentistry, which refers to the use of technologies, such as mobile communication devices, to deliver dental services and health education activities [19]. In *Dialogue 13*, the HP's suggestion to continue the conversation privately illustrates the delivery of health education through remote care, characterizing a teledentistry practice. This approach has emerged as an alternative for providing health guidance while strengthening the relationship between HPs and patients [18]. Similarly, another study identified a similar scenario, highlighting teledentistry as a tool that can be used by HPs for oral health promotion, particularly through text messages and mobile apps [20].

Teledentistry gained particular prominence during the COVID-19 pandemic [21], when limited access to in-person dental care led digital technologies to become an accessible resource for addressing health-related concerns [8,18]. In the *Unanswered Questions* section, mothers sought guidance regarding their children's oral health during this period, using the group as one of the available sources of professional support. This finding further reinforces the potential of WhatsApp as a tool for delivering health guidance and information.

However, these digital interactions also reveal potential risks and limitations. In *Dialogue 9*, 1 mother compares her experience of bruxism in adulthood with another mother's report of bruxism in her child during infancy. This example illustrates the risk of sharing inaccurate information that is not supported by scientific evidence. This is particularly important because bruxism is considered a common finding in early childhood [22], whereas in adults it is associated with different etiologies [23].

Another example is observed in *Dialogue 17*, in which a mother recommends applying gentian violet to the infant's mouth. Information shared by individuals without health care training may contribute to the phenomenon known as an infodemic, characterized by an overabundance of information, often including unreliable content, that can compromise health promotion [24]. A similar situation is observed in *Dialogue 12*, where a participant states that soft teething rings should not be used because they could interfere with breastfeeding. This recommendation contradicts current evidence supporting the use of soft, flexible teething rings because of their significant soothing effect during tooth eruption [25]. Therefore, unreliable information may circulate within the group, highlighting the importance of HPs in providing accurate, evidence-based guidance [24].

Taken together, these findings emphasize the importance of the presence and active mediation of HPs. Their involvement is essential to provide technical clarification, prevent the

XSL•FO
RenderX

dissemination of inaccurate information, and promote access to reliable health information. Conversely, the absence of such active mediation may increase maternal uncertainty and contribute to the spread of misinformation [24].

Although inaccurate information was shared by some participants within the group, the findings also identified mothers who demonstrated knowledge related to children's oral health. In *Dialogue 5*, for example, 1 mother critically assessed the situation by suggesting that tooth eruption could be the cause of her infant's discomfort, demonstrating a higher level of oral HL. This ability reflects critical appraisal skills [4,5], as she associated a clinical sign—irritability, which is commonly related to the eruption of primary teeth [17]—with the timing of tooth eruption.

In *Dialogue 7* and *Dialogue 10*, mothers sought information regarding the appropriate use of medications and oral hygiene practices for their children, suggesting more advanced HL skills by demonstrating the ability to seek, understand, and apply health information—competencies typically associated with individuals who are better able to manage health-related situations, as described in the literature [5]. These HL skills were also evident in other situations, including mothers' vigilance regarding their children's oral health, as observed in *Dialogue 13*, and their confidence in discussing bruxism and recognizing the importance of early dental care, as illustrated in *Dialogue 16*.

Conversely, *Dialogue 8* illustrates HL skills that were still developing. The mother's uncertainty regarding the correct administration of the medication, even after receiving guidance, suggests difficulties in understanding and applying health information in practice. This dialogue reflects competencies consistent with more basic levels of HL, in which health information is applied with less autonomy than in more advanced manifestations of HL [5].

Taken together, these findings indicate predominantly advanced manifestations of HL among the participating mothers, reflected in a more proactive attitude and a greater understanding of children's oral health information. This familiarity with the topic was demonstrated not only through the ability to interpret health information but also through the ability to share it with others, thereby contributing to collective knowledge [5]. Furthermore, greater attention to children's oral health care was observed, consistent with previous studies which show that higher levels of maternal HL are associated with increased attention to child health care [6,26].

Limitations

This study presents some limitations. First, the number of text messages collected for the analysis of infant oral health is small, which restricts the analysis and may not reflect the diversity of experiences among mothers. Second, as this research is based exclusively on text messages, it was not possible to directly evaluate the impact of the information on mothers' daily lives, which limited understanding of the effectiveness of digital technologies within health education processes. To address this, complementary data, such as interviews, observations, or objective outcome measures, would be necessary. Given these limitations, it is recommended that future studies use mixed methods, integrate impact measures, and include longitudinal evaluations, in order to deepen the understanding of the effectiveness of digital technologies in mothers' health education processes.

Conclusions

WhatsApp proved to be a useful tool for mothers seeking guidance related to infant oral health. Participants reported positive impacts resulting from the guidance received from HPs, as well as the peer support built within the group. Furthermore, the study allowed for the identification of a diverse range of patterns related to the competencies and limitations in infant oral HL within the studied population, such as empowerment, autonomy, insecurity, knowledge gaps, and misinformation.

Acknowledgments

The authors thank the Curitiba Maternal and Child Health Cohort (COOSMIC) for their support and for making the data available that enabled this research.

The authors used the generative AI (GenAI) tools ChatGPT (OpenAI; [27]) and NotebookLM (Google; [28]) to support the preparation and revision of this manuscript. These tools were specifically used for linguistic support and readability enhancement (including grammatical correction and suggestions for text revision), structural standardization according to the journal's guidelines, and technical translation of sections of the manuscript. Although the GenAI tools generated draft text and translation suggestions, all outputs underwent active curation, critical review, and substantial revision by the authors. The authors reviewed and verified all scientific content and accept full responsibility for the integrity of the final manuscript. The transcripts of the interactions with the GenAI tools are available in Multimedia Appendix 1 (ChatGPT) and Multimedia Appendix 2 (NotebookLM), respectively.

Funding

The authors declared no financial support was received for this work.

Data Availability

The data used in this study are part of the database of the COOSMIC and consist of sensitive secondary data derived from private WhatsApp (Meta Platforms, Inc) interactions between participants and health care professionals. Due to the ethical, legal, and privacy restrictions established for the COOSMIC cohort, these data cannot be shared publicly or deposited in open repositories.

Abstract

Background: In the United States, Black mothers and their infants experience higher rates of maternal and infant mortality than other racial or ethnic groups. North Carolina mirrors national trends with worse perinatal outcomes for Black families compared with other groups. Most ongoing efforts to address these disparities focus on policy and systems change. Few initiatives focus on education and resource navigation for families.

Objective: This study aimed to design an online resource hub to provide information to support timely access to care and resources to improve perinatal health outcomes for Black families in Mecklenburg County, the largest metropolitan area in North Carolina.

Methods: We used an iterative community-informed process, including focus groups and meetings, to develop and refine the layout and content of an informational website. We conducted focus groups during 2022 and 2023 with Black mothers (n=14) who had given birth in the prior 2 years or were pregnant. A semistructured interview guide explored participant perspectives on (1) information that would be most helpful during the perinatal period, (2) website usability and content, (3) appropriateness of imagery and topics, and (4) effective dissemination strategies. Additionally, the research team met regularly with a multisector community partner group to get feedback on website iterations and solicit community resources to include. All content was reviewed for health literacy. Focus group participants were recruited through local clinics and partnering community-based organizations. Our multisector community partner group included individuals representing public health, patients, providers, social services, and health system leaders. The Reach, Effectiveness, Adoption, Implementation, and Maintenance framework was used for evaluation.

Results: Key themes for website focus areas included (1) vetted information presented in lay terminology, with tools to identify local, affordable, and culturally competent care; (2) information related to the week-to-week changes they could expect during pregnancy; and (3) alternative birthing options. The most common suggestions for improvement related to the navigation, amount of text, color scheme, and the use of images. The final Mecklenburg Birthing Connections resource hub provides educational and informative resources for every stage of the perinatal care journey, from preconception to childcare, and links to community resources to address health care and social needs. Results from outreach and marketing efforts to increase awareness of the resource within the community had a broad reach. In-person events attracted >800 community members and social media marketing

XSL•FO
RenderX

engaged >145,000 unique accounts. Focus group discussions revealed that Black mothers feel that the website addresses important informational needs for Black families.

Conclusions: Partnership with community members enabled the design of a tailored online tool for providing timely information to educate and empower Black families. Ongoing maintenance and dissemination may help address local inequities in perinatal health outcomes.

(JMIR Pediatr Parent 2026;9:e71161) doi:10.2196/71161

Introduction

Maternal and infant mortality rates in the United States far exceed those of other high-income countries. In the United States, more than 700 women die of pregnancy-related complications each year, and approximately 50,000 women experience severe maternal morbidity [1]. In 2022, there were 22.3 maternal deaths per 100,000 live births, representing 817 women who died from maternal causes [1]. Infant mortality rates are on the rise, increasing from 5.4 deaths per 1000 live births in 2021 to 5.6 deaths per 1000 live births in 2022 [2]. Underpinning these stark statistics are persistent racial and ethnic disparities that have yet to be comprehensively addressed by the US health care system. Black and American Indian and Alaska Native (AIAN) women are more than 2-3 times more likely to die from pregnancy-related complications [1]. Black, AIAN, and Native Hawaiian and Other Pacific Islander experience higher preterm births, low birthweight births, or births where they receive inadequate or no prenatal care [3]. Consequently, infants born to Black, AIAN, and Native Hawaiian and Other Pacific Islander women have higher mortality rates than their White counterparts [3].

Several strategies have been proposed to mitigate disparities in maternal and infant health. Ongoing policy initiatives are aimed at the promotion of expanded access to prenatal and postpartum care and coverage for Medicaid beneficiaries who are disproportionately Black, Hispanic, or AIAN [4]. Other efforts have focused on improving the racial diversity of the maternal health workforce to match that of the population [5,6]. Community-based programs such as Healthy Start [7,8] that offer care coordination and service referrals, and home visiting programs [9,10] are other promising strategies. In addition to addressing these structural determinants, there remains a need for person-centered and community-centered approaches that equip and empower families with information to navigate resources available to support their perinatal care needs.

Digital media tools, including websites, mobile apps, SMS, or discussion forums, have been shown to reduce barriers to traditional forms of perinatal care and increase accessibility [11]. For example, digital tools have been used to provide educational information regarding reproductive life planning, postpartum care, anxiety reduction, and health management [12-16]. In a systematic review of 55 studies of digital patient education interventions in the perinatal period, more than two-thirds of studies (n=38) reported a significant positive outcome related to improved patient knowledge, emotional benefit, or improved health behaviors. These tools have the potential to complement other efforts aimed at reducing maternal and infant health disparities by increasing patient empowerment and self-efficacy, supporting patient-provider relationships, and strengthening connections to community resources that lead to improved health outcomes [17,18].

Perinatal populations have indicated a preference for digital health resources that highlight what is typical to expect during pregnancy, provide access to a provider when needed, and offer information on fetal development [19]. Another important consideration in the development of perinatal digital health tools is the quality of health information hosted on these platforms. A scoping review of 30 studies by Li et al [20] concluded that perinatal women were dissatisfied with the quality of maternal and infant health information available on digital media, raising skepticism about the credibility of those delivering the information, the irrelevant or repetitive content amid an overwhelming amount of information, and the lack of scientific evidence. Platform usability and commercialization of digital media platforms have also been criticized by perinatal women using digital media platforms for health information [20].

The increased prevalence and use of digital media provide an opportunity to deliver perinatal health information directly to Black families in health care and community settings. Approximately 87% of Black adults own a smartphone and 94% use the internet [21]. Yet, few digital tools are tailored to the needs of Black people. There is scarce research on the development and testing of digital tools specifically designed to address maternal and infant health disparities among Black birthing people. One study testing the effect of a culturally tailored conversational agent for preconception health education among 528 Black women from 35 US states found a 16% increase in action to improve preconception health risks among intervention versus control participants [22]. Exploring different avenues for digital health research among historically underrepresented perinatal populations is critical as the field moves forward. Research on tailored digital tools that span the life course may further enhance efforts to improve disparate perinatal outcomes.

Guided by the literature, we designed a health system–hosted online resource hub to raise awareness, educate, and empower Black birthing people and their families. The online resource hub was an output of a larger project called the Perinatal Access to Care Campaign, which aimed to provide information to support timely access to care and resources to improve perinatal

XSL•FO
RenderX

health outcomes for Black families. This paper describes the collaborative and iterative design process and early evaluation of the online resource hub and provides recommendations for future research and implementation.

Methods

Overview

We followed a community-engaged participatory action research approach. Community engagement is defined as "the process of working collaboratively with and through groups of people affiliated by geographic proximity, special interest, or similar situations to address issues affecting the well-being of those people" [23]. To that end, we used a collaborative approach guided by an established multisector partnership group, the Bridges Community Partner Group, which served as a steering committee across all phases of project design and execution. The Bridges Community Partner Group prioritized informational resources as a need for the community and participated in the curation of content and resources.

Setting and Participants

This project was conducted in Mecklenburg County, North Carolina, a large metropolitan area with more than 1 million residents. The US Census indicates that 33% (383,645/1,163,701) of residents identified as Black or African American in 2023 [24]. Racial and ethnic disparities in infant mortality in Mecklenburg County mirror state and national trends, with Black infants 2.6 times more likely to die before their first birthday than White infants in 2021 (12.6 vs 4.8 deaths per 1000 live births) [25]. At the state level, the North Carolina Perinatal Health Strategic Plan provides guidance to improve maternal and infant health by addressing social and economic inequities, strengthening families and communities, and improving health care for all people of reproductive age [26]. Within the county, Mecklenburg County Public Health leads initiatives to improve maternal and child health, including home visiting programs, care management, and community health worker programs [27]. Atrium Health is a large not-for-profit health care system headquartered in Mecklenburg County, which delivers the full spectrum of care, including maternity care and pediatric care, through its hospital and outpatient clinic locations. Atrium Health extends care into the community through a variety of programs and partnerships [28]. This project was led by a multidisciplinary team of investigators from Atrium Health in partnership with collaborators from Mecklenburg County Public Health and the University of North Carolina at Charlotte.

Members of the Bridges Community Partner Group were identified through a snowball approach. Snowball sampling is a method used to identify individuals from a specific target population and involves starting with a small initial group and then using referrals to identify additional group members [29,30]. Beginning with an initial group of members from departments across Atrium Health, the group was expanded to include additional internal and external partners and community members to ensure representation of diverse perspectives including birthing professions, public health, social services, community, patient, provider, health system, and research, with a final membership of 42. From August 2022 through August 2024, monthly meetings were scheduled virtually for 1 hour in the afternoon to provide the group with project updates and seek input from partners. All meetings began with a reflection on current news and events related to perinatal health to build common ground around the group's work. Meetings included discussions on the progress of the project and perspectives on the campaign development from the initial website wireframe through the marketing strategy for disseminating the resource.

Ethical Considerations

The Wake Forest University School of Medicine Institutional Review Board reviewed this project and determined that it did not meet the federal definition of research involving human participants, with no need for continuing review (IRB00087620). Verbal consent was obtained from all focus group participants prior to data collection. Focus group participants received lunch (in-person sessions only) and were offered a US $50 prepaid debit card as compensation for their time. Survey data were collected anonymously, with an acknowledgment that participation was voluntary and that data would be reported in aggregate. No compensation was provided for survey data collection. All data were stored without identifying information to preserve privacy and confidentiality.

Conceptual Frameworks

We used a life course perspective to guide project design. The life course perspective posits that observed health and health outcomes are the cumulative result of experiences that happen prior to birth and throughout the lifespan [31]. In the case of Black infants, a life course approach highlights the importance of accessing health care across the life course, investing in community building, and closing the education gap, among other strategies [32]. Extending this perspective, we focused on providing education and resources that spanned preconception and prenatal care in addition to delivery, postpartum, and early childcare experiences. The racism as a root cause framework [33], a solutions-focused approach for addressing racial health disparities, also informed our approach. Using this framework, we devised strategies to address the framework's 4 domains with a specific focus on long-term impact (Textbox 1).

XSL•FO
RenderX

Textbox 1. Applying racism as a root cause framework to the development of an online resource hub.

Strategies applied for each domain of the racism as a root cause framework:

- Precise impact
  - Target Black mothers and caregivers.
  - Identify target zip codes with >50% Black, >9% low birth weight (county median), and median age of <40 years.
- Systems change
  - Develop internal messaging and provider-facing communication about campaign.
  - Connect with decision makers regarding current policies about where women can go for care.
- Long-term
  - Develop a website with information that can be updated beyond the campaign.
  - Create a plan for keeping information current.
- Reparations
  - Invite Black mothers in target communities to focus groups and pay them for their time.
  - Use feedback from Black community members to guide approach (how, what, and where).

Iterative Website Development

There were several iterations of the website content beginning with the wireframe, or alpha scripts, in March 2023. The evolution of the website was grouped into 4 major stages (alpha, beta 2.0, beta 3.0, and beta 4.0) representing major transitions in website design and content curation over an 18-month period. Feedback from focus groups and our community partner group informed each stage of iteration.

Focus Groups

Across the study period, we held 5 focus groups with community members to gather information on the content that would be most useful to include on the website, usability of the design, and feedback to guide development through the various iterations. Focus group participants were recruited from community organizations located in target zip codes and through associations with the Bridges Community Partner Group. Residents of Mecklenburg County were eligible to participate in focus groups if they identified as Black or African American, were aged 18 years or older, were pregnant at the time of participation, or had a baby in the past 2 years.

Four focus groups were held in person at locations in the community (a local recreation center, a local library, and a residential care organization for expectant mothers). One session was held via videoconference. The first 2 focus groups were held in December 2022 (prior to initial website prototype), and subsequent sessions occurred in August, September, and October 2023. A semistructured interview guide developed based on literature review and input from our community partner group explored participant perspectives on (1) information that would be most helpful during the perinatal period, (2) website usability and content, (3) appropriateness of imagery and topics, and (4) effective dissemination strategies. A total of 14 Black mothers participated across all sessions, with some attending up to 2 sessions. An informed consent document was reviewed with participants prior to the start of each focus group, and verbal consent was obtained from all participants. Focus groups lasted approximately 1 hour and were recorded and transcribed. Focus groups were designed to get iterative feedback on the development of the resource hub. Data collection continued until no new themes emerged. Thematic analysis was used to identify key themes and recommendations across sessions to inform the iterations of website build. Three members of the study team (HB, MI, and YT) led data analysis, and discrepancies were resolved via discussion among all study team members.

Community Partner Meetings

In addition to collecting feedback from focus groups with Black mothers, the Bridges Community Partner Group and the project team also contributed feedback to guide the development of the website in a series of iterations. The Bridges Community Partner Group met once a month virtually to review project updates and solicit input on content and delivery of information for the online resource. Biweekly, the project team met to review partner feedback, identify additional resources based on that feedback, and discuss the organization of the information on the website. Changes to the copy, organization of content, or design were collated by a project manager, who organized information into a script for the health system's website development team to implement.

Language and Health Literacy

All website content was framed using a strengths-based approach. Strengths-based approaches are increasingly used in health interventions to give agency and empower the target audience to take action to achieve their goals for health and well-being [34]. We incorporated language such as "I want" rather than "I need" and imagery that appropriately reflected the target audience. It was important for the website to be relatable to community members to encourage connection and relevance to their own care planning. Content was also reviewed for health literacy to ensure accessibility to a broad audience.

XSL•FO
RenderX

Marketing and Outreach Campaign

We collaborated with the health system marketing team to design and implement a marketing and outreach campaign for the website. We used the Charlotte-Mecklenburg Quality of Life Explorer [35] to identify target neighborhoods with >50% Black population, median age <40 years, population size >1000, and low birth weight rate >9% (the county overall rate). We identified 9 neighborhoods across 4 zip codes (28205, 28206, 28208, and 28217) that became targets for marketing and outreach following review and input from our community partner group. To assist our outreach efforts, the marketing team developed flyers in both English and Spanish for distribution at community events and clinic locations and via community organizations and partners. The marketing team also developed a campaign that ran from August to October 2024 and included advertisements through the Atrium Health social media channels on Instagram and Facebook as well as out-of-home marketing (billboards) across the target zip codes.

Evaluation Framework

We used the Reach, Effectiveness, Adoption, Implementation, and Maintenance evaluation framework [36] to assess the early impact of the online resource hub and our marketing and outreach efforts. Reach was measured using website and social media statistics, along with attendance at community events. Website traffic was captured by unique visit data and QR code scan totals driving traffic to the site. Social media metrics included impressions, link clicks, likes, and shares. Billboard impressions, a measure of actual and potential ad views based on traffic patterns, were provided by our marketing partner. At community events, attendance was used as an indicator of website reach, as attendees were informed about the resource or received promotional materials. Effectiveness was measured using qualitative feedback from community members. Adoption and implementation in the short term were assessed with an anonymous survey sent to the Bridges Community Partner Group. The 10-item online survey assessed partners' perspectives on whether the campaign met the intended goal, overall satisfaction with the website, and the website usability, readability, accessibility, and cultural relevance. In addition, partners were asked to report how they were disseminating the resource to their personal and professional networks. As part of the final email to thank the partner group for their effort on the project, a request to participate in the feedback survey was embedded in the email with a response window of 2 weeks. A single reminder was sent. This process feedback collected voluntarily did not constitute human participants research or require institutional review board review. Survey results were reported as counts and percentages. Finally, maintenance was assessed by our ability to develop a plan for maintaining and updating website content and integrating it into routine health system workflows.

Results

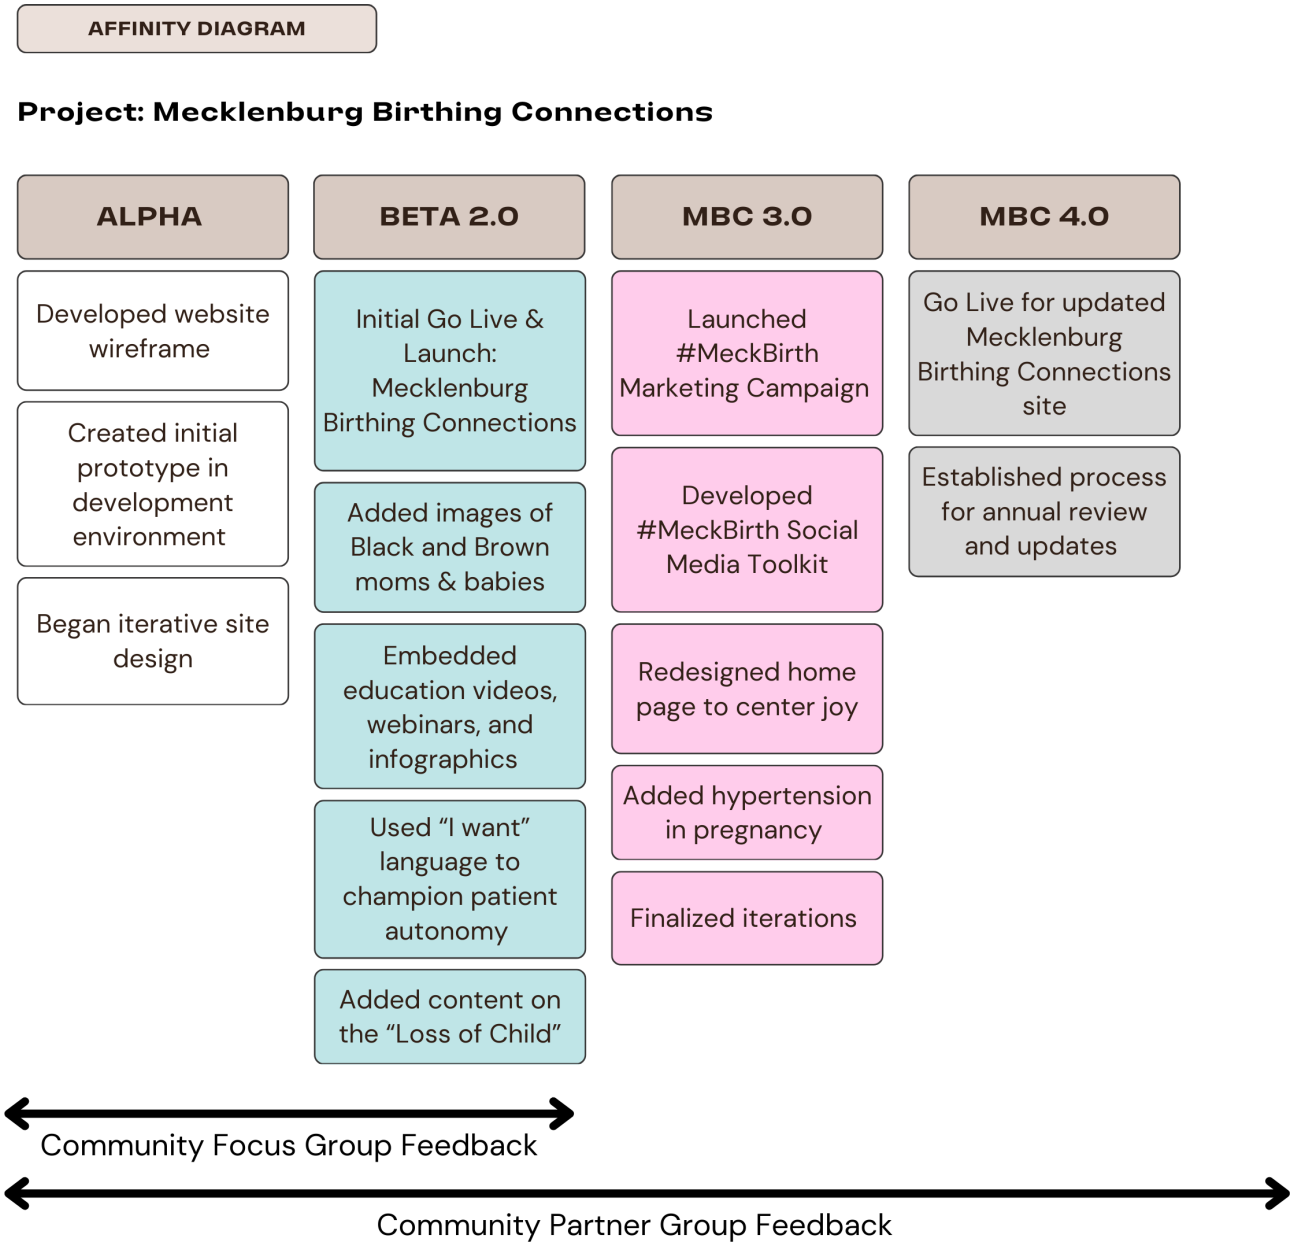
Key Themes From Focus Groups and Community Partner Meetings

Themes from initial focus groups informing the website design are included in Table 1. Black mothers participating in the focus groups shared what they would like to see in an informational resource. Key themes for focus areas included vetted information presented in lay terminology, with tools to identify local, affordable, culturally competent care, information related to week-to-week changes to expect during your pregnancy, and alternatives to the care options of the hospital. Participants favored having information in a mobile app but were open to having the information in a mobile-friendly website, which was the most feasible option for the project. These findings were reviewed with community partners who agreed with these focus areas and added content for caregivers and connections to community resources.

XSL•FO
RenderX

Table . Themes from focus groups with Black mothers to inform initial website prototype. Participants were asked about their informational needs and what to include in a resource for Black families.

Theme	Representative quote
Have vetted and distilled information, as to not overwhelm.	"You don't want to go too crazy on the Internet. Because I have tried to diagnose myself with certain stuff, and you'll get scared."
Include current and updated information.	"With my third daughter, it had been a while, and I had nursed, but I needed a refresher."
Have a way to save pregnancy-related details.	"I can't keep up with that stuff [scheduling regular specialist appointments]."
Include personalized recommendations.	"It was like, they read a book. And they thought that book applied to every patient."
Have information on what to expect, week-to-week, during your pregnancy.	"Being able to map it out, so that we can mentally be prepared."
Answer basic questions about pregnancy.	"There was this assumption that I should know. But it's my first time. Why would I know?"
Provide information on sources of culturally competent care.	"I was literally calling saying, hey, do you have a doctor that looks like me?"
Foster community and allow for the sharing of birthing/pregnancy experiences.	"If no one does it for us, we have to be able to seek out things. You need to know who you express these concerns to along the way."
Discuss and explain affordable alternatives to the care options of the hospital.	"I felt like the only option they were trying to give was medicine."
Be comprehensive.	"...I was given an app…but I will say, interface-wise, compared to What to Expect and all that, I don't like the app. So, I don't even really use it because it wasn't as user-friendly and didn't have as much information…it would have made a difference for me to have all [the information] in one place. Because I wanted to like the one they gave me. The doctor said I should download and keep up with it, but I didn't like it. It didn't have all the things I felt it needed to have."



Black mothers attending focus groups where drafts of the website were reviewed had a positive initial reaction to the organization of the website, finding the organization and esthetic clear, and the naming communicative of the site's purpose. The most common suggestions for improvement related to the navigation, amount of text, color scheme, and the use of images. Focus group participants expressed shock at the statistic on the home page, which revealed that Black infants were twice as likely to die as White infants in Mecklenburg County. This topic came up often in feedback, with community partners recommending a "focus on joy" on the home page along with the benefits of the website. Community members still found the statistics informative and recommended that they appear less prominently on the page. Mothers found the use of images containing Black women and babies comforting and familiar, making the information personal to them. Additional feedback included providing more information on topics such as insurance, healing milestones in the postpartum period, lactation, pregnancy symptoms and complications to be aware of, resources for dads, honoring the loss of a child, and changing family dynamics.

Iterative Website Evolution

Major stages of website development are outlined in Figure 1. In the alpha stage of development, the website wireframe began as a PowerPoint slide deck that provided a general layout of the website content with sections for information on preconception care, pregnancy, postpartum, early childcare, and community resources as informed by focus groups and meetings with community partners. Once the general layout was approved by our community partner group, we started to curate content in a document with headers, text, and links. Content was curated from reputable websites such as the Centers for Disease Control and Prevention, American College of Obstetricians and Gynecologists, and from experts within our community partner group. We shared the copy of the curated content with the Atrium Health Marketing and Web Design team, who then created the first website prototype in a development environment behind the health system firewall.

XSL•FO
RenderX

Figure 1. Stages of development of the Mecklenburg Birthing Connections online resource hub.

The beta 2.0 stage included additions to the resource beginning with the selection of a website name, Mecklenburg Birthing Connections, which was voted on by our community partner group. We built out linkages to the health system's community resource hub, a searchable database of community resources by zip code, for topics including housing, childcare, and food. We also developed and added 27 infographics highlighting select website content in a brief, visually pleasing format. Other modifications during this stage included adding introductory text with header images to each page and reviewing website language to ensure alignment with goals for empowering our target audience. New topic areas added included elective abortion, miscarriage, and induction. This phase of development included iterations for content, text, or format and concluded in April 2024 with the official go-live of the public-facing website [37]. This marked the end of the primary content development phase. To celebrate the official launch of Mecklenburg Birthing Connections, the project team hosted a community forum and resource fair to bring awareness to the newly launched resource, collect feedback, and connect community members to local organizations serving families during the perinatal period. This also marked the beginning of grassroots community outreach to increase awareness of the resource within the community.

The 3.0 stage had a focus on dissemination and expanding partnerships. Our grassroots approach involved identifying and participating in local community events focused on maternal, child, and family well-being. We prioritized events that focused on Black families and events that focused on families with low incomes. Events included community resource fairs, health fairs, conferences, walks, runs, and other virtual speaking opportunities within the health system (ie, local provider meetings) and the local community. We used this approach to reach people living in the community and those serving in health care and social service organizations. A central output of our outreach activities was identifying new partners and resources to add to the website and expand our reach. For example, the

XSL•FO
RenderX

project team partnered with local doulas and a local university to cosponsor a webinar titled, “Black Birthing Matters” on the role of doulas, midwives, and obstetricians in the birthing room. The webinar recording was subsequently added to the website as a resource. Another collaboration with a local social service organization to cohost an event focused on fathers also provided an opportunity to solicit feedback from fathers on the content of the online resource. Other modifications to the website at this stage included a redesign of the home page, addition of a social media tool kit for sharing with community partners, and a collaboration with another health system initiative to build out content on hypertension in pregnancy, which disproportionately affects Black mothers.

The 4.0 stage marked the final phase of development. We obtained sign-off from our partners and closed the website for major revisions. The final Mecklenburg Birthing Connections website includes educational and informative resources for every stage of the perinatal care journey, from preconception to childcare, and links to a searchable database of community resources to address health care and social needs. In addition, downloadable infographics highlighted vital website content in a graphically engaging format.

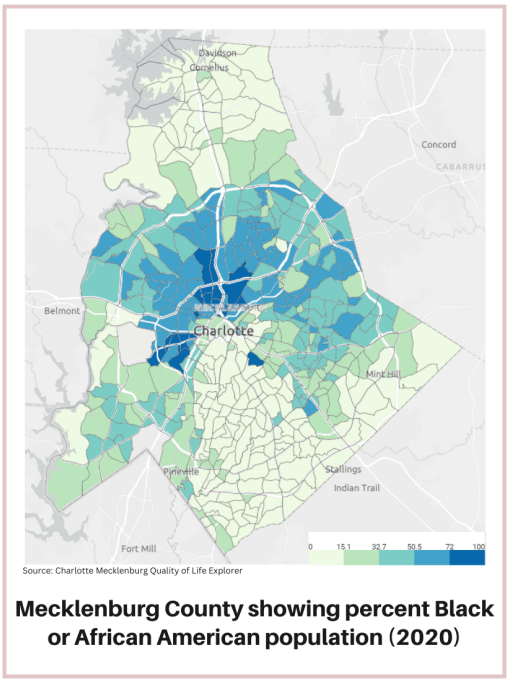
Marketing and Outreach Campaign

Reach

Community outreach events are outlined in Table 2. Across 13 events between March and October 2024, we reached more than 800 community members. Events included conferences, networking meetings, webinars, and community forums. In addition, we delivered 1170 flyers and rack cards across 9 clinic and community locations for further dissemination.

Table . Community outreach activities.

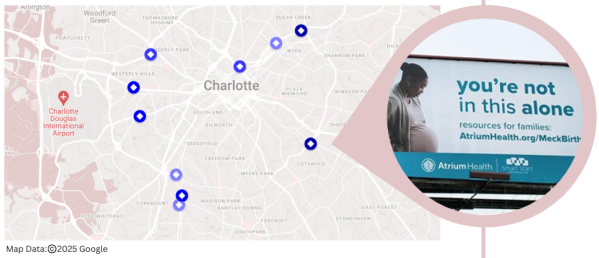
Event title	Date	Type of event	Host	Numerical reach, n
Atrium Health Nurses Meeting	March 27, 2024	Clinical Leaders Meeting	Atrium Health	60+
MBC[a] Community Forum	April 17, 2024	Community Outreach	MBC Project Team	60+
Community Health Worker-Resource Fair	April 20, 2024	Community Outreach	Atrium Health	150+
Black Maternal Health Conference	April 11, 2024	Conference	Care Ring	100+
Black Maternal Health Week Walk	April 20, 2024	Walk/Run	Care Ring and BirthRight	30
Regional Breastfeeding Conference: 25th Annual Mother’s Special Gift Breastfeeding Conference: We’ve Come a Long Way Baby!	April 22, 2024	Conference	Area Health Education Center	30
Public Health Lunch & Learn Webinar	May 22, 2024	Webinar	Mecklenburg County Public Health	10
Queen City Community Connect Coalition- Q2 Meeting	June 4, 2024	Networking and Advocacy for Community Health Workers	Queen City Community Connect Coalition	30
Superman & Me: Celebrating Fatherhood	June 22, 2024	Community Outreach	MBC Project Team and Smart Start	15
Meck Pre-K Orientation	July 20, 2024	Orientation for new Pre-K families	Smart Start	60
Hey Moms, Hey Dads	August 3, 2024	Community Outreach	Department of Health and Human Services	150+
Black Birthing Matters	September 20, 2024	Webinar	MBC Project Team and Charlotte MCH[b] Workgroup	136
Jace’s Journey 5k Run/Walk	October 26, 2024	Walk/Run	Jace’s Journey	50+



[a]MBC, Mecklenburg Birthing Connections.

[b]MCH, Maternal Child Health.

Marketing campaign results are summarized in Figure 2. Paid social advertising reached 145,932 unique accounts and resulted in 789,336 impressions (the number of times individuals were exposed to ads) and 1183 link clicks. Engagement with posts on social media reached 1237. Billboard placement was optimized to high-traffic street posters in select zip codes to drive high impressions efficiently. Billboards were placed for 6 weeks from August 12 to September 22, 2024, with a total reach of 4,094,072 impressions (number of times individuals were exposed to billboards) across 10 locations.



XSL•FO

Effectiveness

Qualitative feedback from community members captured website effectiveness regarding goals for providing content that met the needs of Black families in a format that was accessible. Major themes included informational gaps for Black families, clarity and organization of content, and practical use and accessibility. Regarding informational gaps, community members found the website informational and helpful for answering questions that are not typically addressed elsewhere. One focus group participant commented, "Yeah, I think it's very informational. It's very detailed. It actually answers a lotta questions that a lot of us may have that aren't given on the regular website." And another shared, "I was surprised that y'all had postpartum depression because it's not really talked about in the Black community a lot. That's a good asset as well." With respect to clarity and organization, community members shared positive feedback about the structure of the website. A focus group participant commented:

> *Feel like it was structured pretty well. It broke it down, the stages of pregnancy, like before. Some people think about it. Some people don't. When you get pregnant, the resources that you can do while you're pregnant to prepare for the pregnancy, and then after the pregnancy. You even catered to those that might have a stillbirth or a miscarriage or somethin' of that sort.*

Community members also shared thoughts on the practical use and accessibility of the website. When asked about how they would use the information, 1 focus group participant responded, "I think I would use this if I was pregnant 'cause it gives you, pretty much, every step. It walks you through most of the pregnancy and the whole being pregnant, after pregnant. I would definitely look into this if I was just pregnant." Another commented:

> *I mean, it's very helpful...I can just come here and get the information, and I can pinpoint exactly what I'm looking for, it's very helpful. I haven't come across anything where I can say, 'Oh. If I can look at this...' If I can go through the information and all in one place, it would be very helpful for me. Yeah. I could even pass it along to anybody else.*

Other themes included inclusivity and representation and community connection and peer support. Community members felt that the website used imagery effectively to represent diverse Black women and recommended more explicit focus on fathers and extended family members. Community members also expressed interest in being able to connect with other parents via support groups and meetups and identified that as an area that the resource hub could improve upon.

Adoption and Implementation

Feedback from the Bridges Community Partner Group was requested following the launch of Mecklenburg Birthing Connections. Six community partners responded to an anonymous online evaluation survey exploring satisfaction with the website and adoption and implementation of the resource. Unanimously, the respondents felt that the goals of the project to provide targeted communication to prioritized communities with poor outcomes were met "to a great extent" (6/6, 100%). Feedback about meeting the goals included, "I believe that the website has become a comprehensive place with information from a variety of partners to represent a variety of resources," and "The focus was targeted to Black mothers and Black birthing parents. The information shared was very specific and with a focused aim." Partners' (n=6) average satisfaction with the overall experience on the website was 8.67 out of 10 (SD 1.21). Website navigation was rated an average of 8.83 out of 10 (SD 0.75). Partners (n=6) assessed the readability of information on the website with an average of 9.5 out of 10 (SD 0.84). Most partners believe that the website meets the needs

XSL•FO
RenderX

of their average client regarding cultural resonance (5/6, 83%), readability (5/6, 83%), and accessibility (4/6, 66%). The other respondents indicated these factors to be "somewhat met."

With the recent launch of the website, partners were asked to share how they have implemented the website within their organization. The majority shared the website with a colleague (4/6, 67%) or provided clients with a direct referral link (3/6, 50%). Two of the 6 (33%) respondents promoted the link in email distributions (eg, newsletters). Only 1 out of 6 respondents (17%) indicated the use of printed materials to promote the website within their organization. When exploring resource distribution outside of their organizations, partners described sharing the direct link with friends and family.

Maintenance

Maintenance of the online resource hub as a tool to promote positive perinatal health outcomes for Black families focused on integration with health system workflows and connections to community. Within the health system, the Women's Care Service Line, which includes oversight of the Department of Obstetrics and Gynecology, was identified as a primary avenue for ongoing dissemination. In addition, we engaged the health system's Community Health Worker team for ongoing dissemination among community members. The plan for regular updates to the online resource hub included adding a feedback link that will be reviewed annually by the project team to prioritize updates and reviews. Future evaluation of maintenance will include tracking visits to the site and gathering input from partners regarding their use of the resource in the community.

Discussion

Principal Findings

Improving maternal and infant outcomes for Black mothers and babies in the United States is an urgent priority [38]. However, many efforts do not fully address the impact of social, economic, or environmental factors that contribute to disparities in maternal and infant health [39], and few focus on education and empowerment for families. Our efforts to develop a community-informed informational resource addressed an important gap by incorporating diverse community perspectives and focusing on the continuum from preconception health to early childhood. Moreover, the integration of this resource within a local health system lent support to ongoing efforts to engage health care providers in addressing social determinants of health, while providing a path for ongoing use and dissemination of the tool. Our focus on the Black birthing experience and patient, family, and caregiver empowerment is an additional unique contribution that community members found useful and needed.

Our work aligns with other similar efforts to address maternal and child health disparities using community-engaged approaches, as recommended by the National Institutes of Health [40]. For example, the Commonwealth Fund supported the development of the Maternal Health Hub operated by the Health Care Transformation Task Force [41]. The Maternal Health Hub is an online resource that contains resources and best practices to enhance health equity, increase value-based health care payment models, and promote public policy to reduce maternal health disparities. Furthermore, the National Institutes of Health Office of Research on Women's Health created a Maternal Morbidity and Mortality Web Portal providing a central hub of information regarding the maternal health crisis.

Similar to our approach of involving vested individuals in the curation of materials, Bower et al [42] describe the development of a Maternal Health Equity Toolkit in Maryland by a work group comprising health disparities researchers, hospital-based improvement specialists, perinatal health providers, and representatives of community-based organizations. Each chapter of the toolkit was reviewed by at least 2 experts, with feedback strengthening the use of inclusive language, logical sequencing of strategies, and action steps. The final product included the engagement of locally based resources by linking patients to community and social services.

Despite comprehensive searches, few papers describe educational websites dedicated to Black maternal health education. Most research focuses on the use of mHealth and social media to provide education, which differs significantly from Mecklenburg Birthing Connections [11,43-45]. A study by McFarlane et al [46] describes the pilot evaluation of a multimedia childbirth education intervention for Black women and their birth companions. The intervention, which involved animations and games that were designed in consultation with a Black doula organization and experts in obstetrics and gynecology, was found to be feasible and acceptable for education on Black maternal health disparities, with moderate impacts on self-efficacy and agency [46]. This study differed from ours in that it was not accompanied by a full website platform and had a specific focus on social support in the hospital setting. However, it provides additional evidence for the need for culturally tailored birthing education for Black families, feasibility of web-based tools, and the benefit of co-design when developing such interventions.

Health System–Community Partnership

The health system–community partnership model used to develop the online resource offered benefits as well as challenges to navigate. Benefits included access to health system resources for web development and marketing expertise as well as a platform to engage providers and administrators on the topic of patient education and empowerment to reduce health disparities. This work also aligned with ongoing efforts within the health system's women's care service line to advance maternal health equity. For example, the health system had launched a women's care bus that toured target neighborhoods with limited access to primary and preventive care and was developing a doula program to address poor Black maternal health outcomes. Challenges experienced were due touncertainty in policies and decision-making hierarchy related to the health system's active mergers and integrations, and shifting timelines due to capacity and prioritization of other projects. This required remaining flexible and maintaining regular communication with health system partners. For example, we had to delay aspects of our marketing plan that depended on health system resources because of competing priorities and begin with grassroots outreach. Ultimately, these opportunities proved to be beneficial

XSL•FO
RenderX

in brand recognition and relationship development, not only with families who may use the website but also with the community organizations who hosted or cohosted events with the project team.

Community partnership was invaluable for achieving a product that community members felt reflected their needs. Including community partners from the beginning and engaging community members in decisions regarding what information to include on the resource hub, identification of additional impactful partners in the community, and review of website content during development phases were important aspects of our approach. This required the project team to lean into principles that build trust, such as acknowledging that our community members were experts who we needed to learn from along the way, and building relationships that would extend beyond the time frame of this funded project [47].

Limitations

Our approach had a few limitations. While we benefited from perspectives of a diverse community partner group that included male and female Black parents and caregivers, we included only Black mothers in our focus groups. Additional data collection from Black fathers in the future would help gather more insights into their informational needs and additional content that would benefit them. The potential for selection bias among focus group participants is another limitation that we were able to mitigate by triangulating focus group findings with community partner feedback. Also, hosting the final website within the domain of an established health care system limited our ability to incorporate resources from organizations identified as competitors. Notwithstanding, we were able to leverage the health system's broad reach within the local community, its many existing community partnerships, and its position as the largest Medicaid provider in the state. Finally, we were able to capture only the early effectiveness of the resource, and the adoption and implementation results were based on small sample sizes. Future evaluation could examine the impacts of the resource hub on perinatal care experiences of community members and assess the adoption and implementation among a broader sample of community members.

Implications for Practice and Translation

Our work offers opportunities for future dissemination and translation in clinical and community settings. For example, this online resource could be used to connect to resources where clinics lack embedded social work resources. The user-friendly online format also allows patients to review content at their leisure, thus bridging gaps in timely access to information. Tools like ours that extend beyond the clinical setting to home and community settings have potential for increased impact on reducing racial and ethnic disparities in care and outcomes by considering the social and cultural context in which patients live [48]. Patient empowerment also aids in the reduction of health disparities by giving patients increased agency in their health care decisions [49]. This online resource was designed to equip patients and families to navigate resources in their communities, a crucial component of patient-centered care. The design of Mecklenburg Birthing Connections as a resource hub further supports its ongoing use as a repository for information about programs and services provided by the health system and community partners to support Black families in the future. Other health systems and communities can adapt our approach by soliciting feedback on local perinatal needs and using those findings to tailor resources in collaboration with families and multisector community-based partners. In particular, with the limited and diminishing resources available to support adequate perinatal health in rural areas of the United States [50], developing tailored resource lists for rural families may help supplement care for high-risk populations. Our tool could serve as a foundation for rural counties surrounding the metropolitan area, or within the state, as some of the listed organizations and community partners have multiple locations.

Conclusions

An online resource hub is a valuable approach for providing timely information to educate and empower Black families and caregivers during the perinatal journey. Community members value having a comprehensive tool that focuses on the perinatal experiences of Black families. Communities seeking to improve access to care for Black families may consider a similar approach to identifying and collating local resources in collaboration with local community members and partners to provide easy access to education and information to address local inequities in perinatal health outcomes. Future efforts should plan implementation evaluations to measure impact.

Acknowledgments

The project team would like to acknowledge Matt Britt and Kara Barner for developing the marketing strategy for the website, Whitney Rossman for administrative support, Ebony Cloud for her input on website and marketing content, Payton Davenport for contributions to the design of website infographics, and the Atrium Health Web Design Team for web design. Thanks to community members who participated in focus groups and meetings informing this project.

Abstract

Background: Creative music therapy (CMT) in preterm infants has been associated with improved health outcomes in both parents and infants while promoting parent-infant bonding. However, access to CMT is limited.

Objective: This study aimed to explore the needs and preferences of parents of preterm infants and health care professionals as a first step in developing a CMT-based mobile health (mHealth) intervention.

Methods: An iterative qualitative study combining multistakeholder online focus groups with mind mapping. Map contributions were analyzed using reflexive thematic analysis.

Results: A total of 20 participants (7 parents, 1 grandparent, and 12 health care professionals) contributed to creating the mind map, offering insights into the identified five themes: (1) aims of the mHealth intervention, (2) desired functions and design, (3) content, (4) important factors for acceptability, and (5) usability beyond the neonatal intensive care unit.

Conclusions: The study highlights critical considerations for designing a CMT-based mHealth intervention. The in-depth user insights gathered will inform iterative development and refinement of the intervention, which will be evaluated in future usability, feasibility, and effectiveness studies.

KEYWORDS

creative music therapy; family-integrated care; focus group; mind mapping; mobile health; neonatology; preterm infants; usability; user needs

Introduction

Globally, an estimated 13.4 million babies are born preterm, which is 9.9% of all births, and this number has been stable over the past decade, with only a minimal decline [1]. Preterm births, defined as delivery before 37 weeks of gestation, are a major cause of newborn mortality and are associated with long-term neurodevelopmental impairments [2-4]. Neurodevelopmental impairments may be triggered through stress responses due to unexpected parent-infant separation and trauma [5], auditory deprivation (eg, lack of exposure to intrauterine maternal heartbeat and the mother's voice), and the overstimulating, stressful, noisy neonatal intensive care unit (NICU) context [6,7].

XSL•FO
RenderX

The traumatic nature of preterm birth, combined with uncertainties regarding the infant's health and future and the stressful situation in the NICU, profoundly affects parents as well, resulting in increased rates of anxiety [3,8], depression [3,8], posttraumatic stress [8], and feelings of helplessness [9,10] or disempowerment [11]. Such psychological issues and the physical separation of parents and infants can impact the parent-infant relationship, interaction, and the formation of a secure attachment—an emotional bond, which is formed in the first 18 months of life [3,12] and is associated with the infant's later socioemotional, behavioral, and cognitive development [3,5,13].

Conversely, in NICUs supporting active parental involvement, such as applying kangaroo-care, improved outcomes have been observed, including reductions in infant mortality and morbidity [14]. This underscores the importance of family-centered care, including free parental access to the NICU and psychological support for parents [15], as well as family-integrating care models with parents being acknowledged as primary caregivers [16].

Building on this foundation, further approaches promoting active parental involvement in the NICU include interventions such as family-integrating creative music therapy (CMT), which emphasizes meaningful multimodal stimulation. CMT uses infant-directed, lullaby-style singing to soothe and gently stimulate infants, while empowering parents through active involvement in the therapeutic process [17-19], that is, music therapy during skin-to-skin contact to foster bidirectional relaxation, attachment, and bonding. Throughout the music therapy process, parents are guided and empowered to recognize their infants' cues and tailor their responses to the infants' state and needs, while humming, speaking, and/or singing in a responsive way. CMT is associated with reduced parental stress and anxiety [20,21] and improved neurodevelopmental outcomes [5,18], as well as parent-infant bonding [20]. Moreover, previous systematic reviews demonstrated various beneficial effects of music on physiological parameters such as heart and respiratory rate, oral feeding, behavior, and stress in preterm infants [21,22], and a Cochrane review [23] confirmed an overall substantial beneficial effect of music and vocal interventions on the preterm infants' heart rate during and after the intervention. Despite these promising outcomes, access to CMT in NICUs is limited [24] due to the limited availability of therapists [25-27].

One way to address this limited access to CMT in the NICU is the use of mobile health (mHealth) interventions, delivered via an app or SMS text messages. They are increasingly applied in health care delivery and offer major advantages such as cost-effectiveness and accessibility compared to traditional face-to-face interventions and usual care [28-31]. Numerous mHealth interventions for parents exist [32], targeting pregnancy and postpartum care [33-36], parenting [35,37,38], and risk of preterm birth [39,40]. However, there is a notable lack of comprehensive mHealth interventions specifically designed for parents of preterm infants and infants born with serious illness, and, to the best of our knowledge, no music therapy-based mHealth intervention exists.

Another important consideration is that commercially available apps may not have been developed and tested with the same rigor as those created in research settings [41]. This raises concerns about their reliability, feasibility, usability, and real-world impact.

Therefore, a research and development (R&D) project was initiated [42]. It aims to develop a CMT-based mHealth intervention delivered through an app to support, coach, and motivate parents of preterm infants and health care professionals in the NICU and later at home to use their voice and music. This, in turn, will improve well-being and the parent-infant bond. The R&D project is based on a user-centered design (UCD) approach—an iterative process that involves end users throughout the whole development process to continuously refine and reshape the intervention's design [43,44]. The UCD approach is complemented by a broader human-centered perspective, which considers emotional, social, and contextual realities in which the intervention will be used. This is especially relevant in sensitive settings such as the NICU [45,46].

This study represents the first working package of this project [42], aiming to explore primary (parents) and secondary (health care professionals) end users' needs and preferences toward such an mHealth intervention. Its overall objective was to provide a basis for further iterative co-design steps, such as developing a prototype of the mHealth intervention, rapid usability testing, effectiveness evaluation, and implementation.

Methods

Study Design and Setting

The study reported in this article is an iterative qualitative study, combining multistakeholder online focus groups with mind mapping and prioritization of results to reach saturation. Study reporting was conducted in compliance with the COREQ (Consolidated Criteria for Reporting Qualitative Research) [47].

The whole R&D project is a collaboration between the University Hospital Zurich Department of Neonatology and the University of Zurich, with the Careum School of Health, part of the Kalaidos University of Applied Sciences, and amiamusica (a charity association dedicated to empowering preterm and high-risk newborns and their families through music). The project's implementation partner is Pathmate Technologies, a company that develops coaching technologies combining medicine and behavioral psychology with data and artificial intelligence. The core research team comprises an interdisciplinary group of senior researchers who have conducted research in the fields of CMT in neonatal care, public health, care and caring, movement sciences, and health sciences and technology, and are experienced in participatory and transdisciplinary research.

Ethical Considerations

The ethics committee of the Canton of Zurich reviewed the study and decided that it does not fall within the scope of the Human Research Act, which regulates research on human subjects in Switzerland (BASEC-Nr Req-2024-00635). The study was conducted in compliance with all national legal and regulatory requirements.

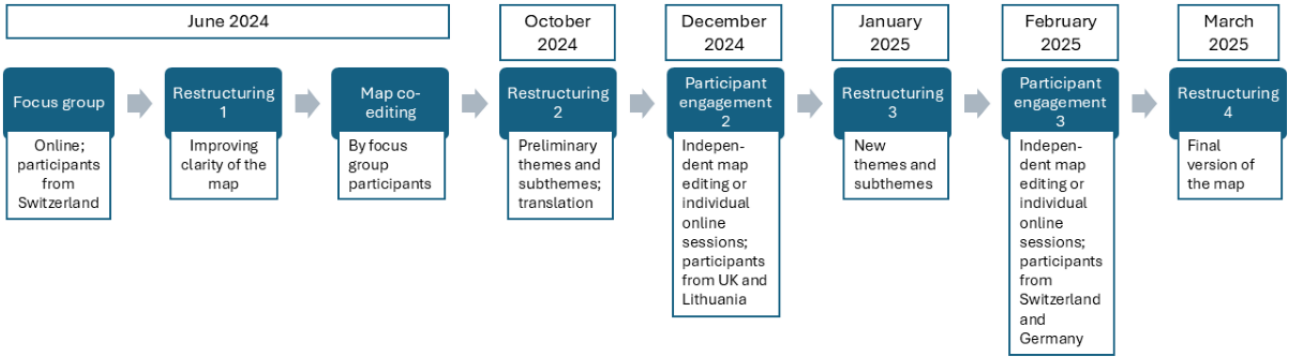
XSL•FO
RenderX

Participants and Recruitment

Study participants were purposefully sampled, including parents and grandparents of preterm infants and health care professionals. We aimed to recruit German- and English-speaking mothers and fathers and, if possible, grandparents, with and without music therapy experience, all of whom experienced preterm birth at least 1 year prior to participation. We sought to include a variety of ages, genders, educational, socioeconomic, and migration backgrounds. Health care professionals, such as nurses, doctors, psychologists, and music therapists, were eligible if they had a minimum of 3 years of working experience in the NICU.

Recruitment was conducted through the parent association amiamusica, University Hospital Zurich, University of Zurich, as well as through professional neonatology and parent networks and foundations in Switzerland, Germany, and the United Kingdom. Potential participants were approached via email by BS, RMSV, FBH, and JS, and before participating in the study, they had to provide digital informed consent using the online survey tool Unipark (Tivian GmbH, 2024).

Study Procedures



ECOUTER Approach

Study procedures followed the first step of a UCD process—user research and analysis—inspired by the ECOUTER (Employing Conceptual Schema for Policy and Translation Engagement in Research) approach proposed by Murtagh et al [48], which is based on iterative creation and coediting of mind maps by a diverse group of participants. The ECOUTER approach relies on flexibility and adaptability and aims to open up discourses. Its crucial advantage is that it can be conducted virtually, making it accessible to a broad range of people by overcoming temporal and physical limitations [48]. Based on the ECOUTER procedures and following previous research that implemented and described the approach [49], our study comprised three steps: (1) participant engagement, knowledge exchange, and prioritization of results; (2) thematic analysis of mind map contributions; and (3) result interpretation and development of recommendations.

Participant Engagement, Knowledge Exchange, and Prioritization of Results

A total of 3 groups of participants took part in this study (Figure 1). First, a 2-hour online focus group session was conducted via Zoom in June 2024 with participants from Switzerland. The session aimed to explore users' needs following a focus group guide developed by BS and FBH. FBH moderated the focus groups, while 3 additional interdisciplinary study investigators (BS, RMSV, and JH) observed the online interactions, took reflective notes, and documented the discussions on the online whiteboard Miro using mind mapping. Afterward, participants were invited to comment on the map and mark the aspects they found most central with stickers.

Figure 1. Study procedures: participant engagement and thematic map analysis.

This mind map served as a basis for two further rounds of participant engagement in December 2024 and February 2025, involving participants from the United Kingdom and Lithuania, and from Switzerland and Germany, respectively. All participants edited the mind map by adding their ideas and marking priorities—either independently on the online Whiteboard Miro or during facilitated individual online sessions with FBH and BS, JH, or JS. Participants were allowed to access the mind map as often as they preferred for a period of 1 week. All focus groups and online sessions were video recorded. We defined thematic saturation as the point at which interaction with the mind map ceased.

Thematic Analysis of Mind Map Contributions and Result Interpretation

The mind map was analyzed, inspired by the principles of reflexive thematic analysis as outlined by Braun and Clarke [50,51].

First, the initial version of the mind map, which was developed collaboratively during the first focus group session, was inspected and reviewed by each member of the research team to gain a deep understanding of the range of ideas and expressions contributed by parents and health care professionals. It then underwent four rounds of restructuring (Figure 1).

A major restructuring occurred in June 2024, immediately after the focus group session, focusing on improving the clarity and coherence of the map for subsequent commenting and prioritization by focus group participants. Another major revision was undertaken in October 2024 prior to translating and sharing the map with participants from the United Kingdom and Lithuania, with a focus on grouping related ideas and further developing and labeling preliminary themes and subthemes. Additional restructuring was conducted in January and March 2025 before and after the final round of participant engagement.

XSL•FO
RenderX

The final version of the map can be found in Multimedia Appendix 1.

In each restructuring phase, themes and subthemes were initially developed by JS and BS and subsequently iteratively edited based on internal feedback loops, including both individual reflections and project team discussions. Themes and their labels were critically examined for internal coherence and distinctiveness. The team repeatedly cross-checked whether the emerging thematic structure reflected the diversity of participant input, while enhancing clarity. Unclear or overlapping themes were either refined or combined. Changes were made collaboratively until team consensus was reached, and no additional codes or themes emerged.

In addition to these 4 major rounds of restructuring, constant modifications by the research team occurred in parallel to participants adding annotations or stickers to enhance clarity and comprehensibility for others. Overall, this iterative coanalysis approach aimed to ensure transparency, thematic depth, and validity in theme development while maintaining the participatory nature of the data, which stemmed from the ECOUTER approach, with participants being allowed to add, relocate, and comment on mind map contributions.

The final step comprised the summary of the map structured by themes and subthemes, and their interpretation.

Results

Participants

The study involved 20 participants who actively contributed to creating the mind map (n=3 from the United Kingdom, n=2 from Lithuania, n=13 from Switzerland, and n=2 from Germany). A total of 7 of those participants were parents of at least 1 preterm infant, and 1 participant was a grandparent, while the group of health care professionals comprised medical doctors (n=3), music therapists (n=5), a psychologist (n=1), and nursing experts (n=2). One participant was both a psychologist and a music therapist. Two of the music therapists were also parents of a preterm infant, but were counted as professional experts as they were enrolled as such. All participants have completed tertiary education.

Table 1 presents the characteristics of the first 2 participant groups. To validate the findings from those groups and following the ECOUTER approach, which seeks to “open up” engagement iteratively and organically [48], the third and final round of participant involvement was conducted in a more open manner. Thus, no assignment of individual map contributions to specific participants was documented, and, as a result, detailed participant characteristics were only reliably collected for the first 2 groups.

Reflexive Thematic Analysis

The reflexive thematic analysis of the board resulted in five themes describing (1) aims of the mHealth intervention, (2) desired functions and design, (3) content, (4) important factors for acceptability, and (5) how the intervention can be used beyond the NICU in ambulatory care. In the following, each theme and its subthemes are described with a focus, where applicable, on prioritized aspects. A graphical overview is provided in Figure 2, while a more detailed mind-map representation, including an indication of which themes were prioritized, can be found in Multimedia Appendix 1.

XSL•FO
RenderX

Figure 2. Overview of themes and subthemes after the final restructuring (restructuring 4). NICU: neonatal intensive care unit.

Theme 1: Aims of the Intervention

Overview

In this first theme, key goals and expectations toward the CMT-based mHealth intervention are described. A central priority of participants was to empower parents to sing to their infants and to benefit from the emotional, relational, and developmental advantages of CMT.

Subtheme: Empowerment to Sing

Participants emphasized the general importance of such an mHealth intervention for parents of preterm infants in the NICU and after discharge. Especially its relevance in NICU settings was highlighted, as they constitute an exposed restrictive space, likely inhibiting parents from singing. Therefore, the intervention's primary goal should be to create a safe space, motivate and encourage parents to use their voices, as encapsulated in the slogan "Your voice is the most beautiful," and ultimately enhance self-efficacy and empowerment. Among all participant groups, especially parents with lived NICU experience emphasized the intervention's role in fostering empowerment in such a restrictive environment. Additionally, the intervention should promote physical and eye contact between parents and their children.

To overcome any inhibitions, participants underlined the importance of an easy introduction to singing without any pressure ("Just be a parent, not a singer"). Strategies include allowing parents to listen first and involving nurses to help create a more supportive and natural singing environment in the NICU.

Subtheme: Added Value

Participants emphasized the potential benefits of the planned CMT-based mHealth intervention, including facilitation of parent-infant bonding, promotion of a sense of security for preterm infants and infants born with serious illness since they are familiar with their parents' voices from pregnancy ("Child feels safe, secured and connected with parents"), and improvement of music therapy adherence. It possibly could help parents to get in touch with peers and therapists and encourage self-care and self-efficacy through a low-threshold entry to CMT. This can help parents to relax, which, in turn, would positively affect their infants.

Theme 2: Design and Functions

Overview

This theme outlines design preferences, functional requirements, and personalization needs for the app through which the mHealth intervention is delivered.

Subtheme: Design

The subtheme design was particularly prioritized by participants. Key thematic design aspects included the need for a "simple, straightforward," and aesthetically "inviting and meaningful design" that is "inclusive," flexible, and respectful of the diversity of potential users.

Participants stressed that the app should be "simple and straightforward," thus user-friendly, easy to navigate, and logically organized ("Keep it simple and sexy"). Potential users suggested the need for a clear and consistent structural design,

XSL•FO
RenderX

for example, a tree-like organization allowing for a continuing progression through the various functions, and emphasized the importance of a simple and intuitive menu with direct selection of the main functions from anywhere. Overall, preventing future users from feeling overwhelmed by complexity was considered key.

Participants also emphasized an "inviting and meaningful design," stressing that the target group must always be kept in mind, that is, parents "should feel addressed in their adult role," which is why the app should not be too colorful. Nevertheless, the style of the app should not be clinical and sterile either, but was proposed to be visually appealing, using a color scheme that would evoke warmth and hospitality. The use of symbols such as the octopus—a global symbol for preterm births—was proposed.

"Inclusive design" refers to the need for barrier-free access, which was emphasized by participants. The app should be accessible to individuals with vision impairments, neurodivergence, learning disabilities, or limited technical skills. Suggested solutions include using neurodivergent-friendly fonts, simple language, and voice control. Additionally, the app should be multilingual, gender-neutral, and avoid biased languages and references to reach a wider audience, achieve international visibility, and overcome language barriers ("address different cultures yet keep it simple").

Subtheme: Functions

In terms of functions, thematic aspects included "interactive features," "recordings," "reminders and news," and "technical functions."

Participants highlighted the importance of "interactive features," which, for instance, enable direct, bidirectional communication between NICU professionals and parents through images, videos, messages, and phone calls, allowing parents to stay informed about their child's development and receive updates while not being present ("being able to share beautiful moments with the children with parents as an achievement from care work [appreciation]"). It was also highlighted that parents could send questions to professionals for follow-up discussions on the ward. However, health care professionals recommended exercising caution to avoid raising unrealistic expectations among parents that health care providers could react upon queries at any time and raised the concern that not being able to account for parents' worries might lead to insecurity and worry, thus leaving them alone with their fears. A parent forum for peer-to-peer communication was also suggested, allowing the exchange of pictures, videos, experiences, and mutual understanding during the time in the NICU and for long-term use at home. Carefully moderating such a forum would be crucial to prevent the spread of harmful information.

Additionally, participants recommended incorporating feedback options for the mHealth intervention to develop and improve constantly.

Another important topic was "video and audio recordings" of CMT sessions and parent-child interactions. These recordings should be both asynchronous for sharing with family and friends and synchronous for involving other family members in real time. Participants also suggested "recordings of lullabies that can be played so babies can hear their mother's voice" and recordings of the baby's heartbeat, especially for palliative care as a special memory of the infant.

The thematic aspect "reminders and news" referred to sending weekly evidence-based updates on the benefits of CMT, which was considered an option for reminding and motivating parents to engage with the app and use their voices continuously ("Motivation for the longer run: Sharing evidence [...] why it is important [health of the baby] along with reminders").

Participants mentioned several "technical aspects" which should be considered, namely offline functionality, compatibility with different systems, the option to download all content "to easily transfer the great memories to the computer or save them on the mobile phone," and support for multiple profiles under a single account (for families with more than one child).

Subtheme: Personalization

Participants voiced personalization of the app's design, functions and intervention content to ensure accessibility and motivation. They suggested a gradual progression through various levels of experience with music, particularly for users who consider themselves unmusical ("Where do you meet someone who describes him/herself as untalented/unmusical [...] maybe via a questionnaire that records where he/she sees him/herself?"). Furthermore, the vocal range (eg, soprano or tenor) should be determined via an app function as a basis for personalized song recommendations.

Theme 3: Content on Music, Health, and Motivational Support

Overview

Participants articulated a range of content-related needs and expectations, emphasizing the app's role as an educational and motivational support tool. The theme "content" comprises the subthemes "educational and motivational aids," "instructions," and "tutorials," referring to practical and voice-use guidance, a "diary" to support memory-making, and assistance with "song selection" to build parents' confidence.

Subtheme: Educational and Motivational Aids

This subtheme describes the communication of "evidence-based information," "information about the newborn/preterm baby," "information about mental health and stress," and "information for health care professionals."

It was deemed essential that the mHealth intervention include empowering messages and "evidence-based information" on the impact of voice, singing, and CMT on child development and parental mental health to strengthen health literacy ("Develop perspectives for parents. It won't be like this forever"). "Information on preterm babies," such as their hearing abilities, way of communication, and milestones of development, was considered valuable. However, it was emphasized to carefully avoid putting pressure on parents due to the varying developmental pace of preterm babies. Instead, parents could be encouraged to track their own personal milestones in the app.

XSL•FO
RenderX

Overall, trustworthy and reliable information was regarded as essential for fostering trust, motivation, and reducing stress resulting from the otherwise stressful search for reliable information. Additionally, motivation to use one's own voice and singing could be enhanced by highlighting the intervention's cost-effectiveness, safety, simplicity, and its significant impact on infants' health, thereby encouraging parents to use their voices as a tool for self-care during moments of helplessness as highlighted in this quote: "Let parents know why music therapy is helpful for their children (inexpensive use of voice with a major impact on health of the baby); simple but very effective, does not do any harm and helps babies grow".

According to study participants, "information for health care professionals" should comprise the same background knowledge on the benefits and impact of CMT as parents, as they may equally be unaware of its impact on newborns and parents, and additional specialist information supporting their interaction with parents ("NICU staff needs to know how families feel on NICU and how music therapy helps them").

Subtheme: Instructions

The subtheme "instructions" was found important but not prioritized compared to the other themes. It comprises thematic aspects related to "NICU code of use," "handling voice and volume," and "preparing for the encounter and touch."

Instructions on how to use the intervention ("the code of conduct") in the NICU included guidelines on phone usage (frequency, duration, volume, and privacy issues) and a reminder that the app is not a substitute for parental presence. Participants recommended instructions on "handling voice and volume" to avoid noise and overstimulation, instead of therapeutic auditory stimulation. Learning how to read and observe the babies' reactions and real-time resonance was considered key to this. Participants emphasized the importance of differentiating between newborns and premature babies in terms of their responses, as expressed in this note: "Newborns appear much more responsive. At the same time, parents need to be aware of the signs of excessive demands on premature babies." A calm atmosphere and touch should be emphasized in the context of "preparing for the encounter and touch," including ideas and possibilities on how to create a calm and private atmosphere in a noisy NICU.

Subtheme: Tutorials

A video demonstration of the app's functionalities and introductory videos on voice and singing techniques were considered essential. Such videos could provide step-by-step guides for future users with limited technological abilities or cognitive disabilities. They were also considered as alternative learning means compared to text-based content only to meet the needs of different potential users and learners, particularly when it comes to singing and music. Participants favored including real-life videos to create a feeling of relatability for parents. Personal videos from other parents sharing their experiences with voice, music, and therapy were seen as additional valuable resources ("Knowing that others are doing it and how they are doing is [in terms of motivation/peer] lets me do this, too"). Such real-life videos may also serve as a means for reducing fear of error when singing and thus support effective learning.

Participants also considered it important to provide a slow, low-threshold introduction to using voice and CMT, starting with speaking, then humming, and finally singing to promote parents' self-efficacy and overcome insecurities. Such gradual progression may support future users in progressing at their own pace, according to their skills and capabilities. Involving music therapists in this might make it even easier ("Creating a caring environment with a trusted person so as not to feel alone/overwhelmed when singing"). However, participants emphasized that gender differences should be considered, with men potentially requiring different types of encouragement compared to women. Overall, a gender inclusive design of tutorials was emphasized.

Subtheme: Diary

A digital memory box or diary function was considered a key added value, allowing parents to store and retrieve photos, videos, and musical moments even after NICU discharge. This feature was anticipated to motivate parents by showing highlights and milestones ("could have milestone markers attached to a photo or short video"), while also preserving memories, particularly for parents dealing with palliative situations ("Dealing with palliative moments from terminal phases as a video moment—a 'treasure' for parents"). Pictures of the baby were expected to encourage milk production and support breastfeeding. The diary function was considered particularly valuable, even among HCPs, as parents are already given diaries to document and remember their time in the NICU and their child's development. Therefore, the diary function could be useful in promoting the app's acceptance and adoption in clinical processes.

Subtheme: Song Selection

This subtheme comprised thematic aspects related to "playlists" and "song of kin." In accordance with participants' preference for personalization, they suggested offering "playlists" with songs tailored to different experience levels, including songs for beginners, to "regain confidence in your own voice (melody with soundtrack, karaoke, or sing-along). It was found important to provide song recommendations for different situations, such as calming or activating songs, and to include songs that could be sung along to or performed as karaoke, supporting the transition from humming to singing.

The implementation of "songs of kin" was found necessary, that is, songs identified as especially meaningful to the parents, which can "bring familiar cultural heritage to the forefront of personalized treatment" [52]. According to participants, the mHealth intervention should "give impulses to what could be a song of kin" and encourage parents to be creative in choosing their own songs, even if these, at first thought, might not be considered baby-friendly. This could empower families to "select songs in an environment, where there is little choice" in order to support feelings of control.

XSL•FO
RenderX

Theme 4: Acceptance

Overview

In contributions clustered under "acceptance," participants discussed a range of practical and systemic factors that are crucial for the intervention's successful implementation and long-term acceptance in the NICU context. These included "integration into existing clinical routines," "implementation strategies," and "equipment availability and hygiene." Furthermore, participants highlighted the importance of "data security and protection" and "updates and topicality." These aspects were mainly emphasized and strongly prioritized by health care professionals.

Subtheme: Integration in NICU Routines

For the intervention to be accepted, health care professionals considered it crucial to take both parents' and their own needs into account and to integrate the intervention into existing NICU routines ("applicability in everyday life required"). For example, the diary function could align with the practice of creating a record of the newborn's time in the NICU ("Keep it simple and combine it with existing information (...) from daily businesses"). One concern shared among participants was the time constraint of health care professionals, which must be considered during implementation. Therefore, the app should include features that simplify or substitute existing processes, rather than adding to the workload. Finally, given the clinical restriction of the use of mobile devices in the NICU, the app should have a clear, strict code of use.

Subtheme: Implementation Strategies

Appropriate promotional or implementation strategies were found to be important to boost acceptance of the intervention. These could include preliminary written information (eg, flyers) and personal information provided by music therapists ("It is important for parents to feel welcomed: there is someone [the therapist] who accompanies me. Sensitivity is required when making first contact").

Subtheme: Equipment and Hygiene

In terms of acceptability, health care professionals stated that if tablets are provided by the hospitals, dedicated tablets for each bed would be needed to ensure accessibility and sufficient hygiene. Proper covers and disinfection should be in place to maintain cleanliness and prevent cross-contamination.

Subtheme: Data security and Protection

Data security and privacy are paramount due to the transfer and storage of sensitive clinical data and pictures of families and health care professionals ("Think about data protection for staff as well. If parents film and record, the personal rights of staff can also be violated. Involve the staff committee at an early stage"). In this regard, licensing was found to be highly relevant to increasing trustworthiness. Participants expressed a preference for the mHealth app to be free of charge, without internal advertising or subscription fees.

Subtheme: Updates and Topicality

Another subtheme was the need for continuous updates of the app. Participants highlighted that evolving needs, particularly those caused by generational shifts, necessitate regular updates ("continue to ensure the involvement of parents because of changing needs between different generations"). A feedback function for continuous improvement was therefore considered key. For example, today's young parents may require gender-inclusive language. Additionally, adaptation possibilities should be considered for international intervention implementation.

Theme 5: Usability Beyond the NICU: Cross-Sectoral Long-Term Use

The final theme focused on the mHealth intervention's application after discharge from the NICU, considering its cross-sectoral long-term use and sustainability. Key thematic aspects included "considering different developmental stages," "using and integrating music at home," "support services and networking possibilities for aftercare issues," and the need to "make data sustainably accessible." None of these aspects was prioritized by participants, but considered add-ons, which would be nice to have.

Overall, to ensure long-term usability, the intervention should be adaptable to "different developmental stages" and age, offering tailored solutions or support for each stage ("Visualize different phases of life and find answers").

Participants suggested providing input and guidance on how to "use and integrate music" into everyday home routines over a more extended period, including both very simple and in-depth information. As during the NICU stay, the app should highlight everyday situations in which music can be used for a specific purpose, such as aiding sleep or animating children ("point out everyday situations the children can be calmed [eg, after a fall] or animated/motivated [eg, when brushing teeth] by music"), also when they are growing up (playful music games).

There was a strong emphasis on the need for ongoing support in the long-term care of preterm infants and on addressing later "aftercare issues" such as difficulties in school. Possibilities included peer-to-peer networking and access to external support services, such as specialized psychologists ("support services for later concerns, as after discharge, you are on your own").

Finally, for long-term sustainability, participants proposed export options for all data, allowing parents to access their data and photos outside of the application and ensuring that the information remains "sustainably accessible" even without continued application use.

Discussion

Principal Findings

The thematic analysis of participant-generated inputs reveals a broad and multifaceted spectrum of user expectations across parents and professional groups for a CMT-based mHealth intervention as a means toward family-integrated care, which supports, coaches, and motivates parents of preterm infants in neonatal care and at home. Our findings underscore the need to develop digital solutions that focus on promoting parent-infant bonding and empowering parents to both sing to their infants and benefit from the emotional, relational, and developmental

XSL•FO
RenderX

advantages of music therapy. Thereby, rather than focusing solely on technical functionalities, participants emphasized a diverse range of needs encompassing a straightforward and inclusive design, educational and motivational content, personalization of functions and content, social support and peer exchange, and features for cross-sectoral long-term use of the mHealth intervention. Health care professionals further stressed the importance of integrating the mHealth intervention in NICU routines to increase its acceptance. These needs reflect a broader understanding of mHealth tools as holistic systems that must consider not only instrumental use but also affective needs to engage users effectively.

The multidimensionality of user expectations beyond technical functionalities has long been recognized in diverse research, for instance on general user needs [53] in the technology acceptance model [54], the unified theory of technology acceptance [55], and in the consumption value theory, which posits that consumer choice is influenced by 5 types of value: functional, conditional, social, emotional, and epistemic [56]. These aspects have gained prominence in research on digital health and mHealth intervention development [57,58] and in the context of mHealth interventions supporting parents during, for instance, pregnancy and postpartum, or in child development [36,59,60]. Most studies agree on the importance of the following components: (1) health promotion, (2) communication—both peer interaction and communication with health care professionals, (3) health tracking, (4) personalization, (5) notifications and reminders, (6) scientific foundation, and (7) patient education [37,41,61].

All these components also emerged as prevalent themes in this study and will be discussed in the following sections, supplemented by a few additional major themes that arose only in our study.

Empowerment and Health Promotion

Most participants expected the app to inform parents about the comprehensive effects of CMT and guide them in using CMT elements to improve their own and their infant's health actively. The combination of information and actionable instructions was seen as a way to increase motivation and foster a sense of self-efficacy, defined as perceived competence [62,63]. Beyond the anticipated increase in self-efficacy, across multiple themes, participants consistently perceived the mHealth intervention as a tool for empowerment in times of helplessness, with empowerment defined as gaining control over health-related decisions and taking actions [64]. This is particularly relevant in the NICU context, where parents often experience a profound loss of agency, and highlights the value of an intervention that helps parents feel in control of their child's health and treatment. Indeed, parental empowerment is a key component of CMT [17,65,66]. It empowers parents, for instance, by promoting their sense of agency and self-confidence [17,67], reducing stress [17,20,68], and enhancing well-being, the parent-infant bond, and interaction quality [69,70]. This aligns with and extends the family-integrated care approach, which redefines parents as primary caregivers in the NICU rather than passive observers [16]. A previous randomized controlled trial suggests that this approach leads to improved outcomes for both preterm infants and their parents compared to standard NICU care [16] or even family-centered care [71,72].

However, while some participants of this study perceived the mHealth intervention as a solution to overcome hesitations to sing in a public space, previous research, which also observed this reluctance to sing in the NICU [70], emphasizes the essential role of guidance and support from music therapists. Similarly, other studies identified personal support complementary to the mHealth intervention as 1 out of 4 crucial factors for adherence to these interventions [73]. This suggests that a blended therapy approach might be needed at the beginning of the intervention, with the mHealth intervention complementing face-to-face interventions to receive the advantages from both [74].

Design: Inclusivity, User-Centeredness, and Simplicity

Given the intervention's intended use across diverse user groups, inclusive design is crucial to ensure accessibility and usability for individuals with different physical, cognitive, and social backgrounds. Moreover, participants highlighted the need for a user-friendly and intuitive design that simplifies interaction.

This is in line with previous research showing that successful technology adoption and uptake depend on perceived costs, such as cognitive costs and self-efficacy beliefs [75,76]. Complex mHealth apps that are complicated to navigate can increase cognitive costs, reduce self-efficacy beliefs, and ultimately reduce the users' willingness to engage with them.

Functions: Communication, Notifications, and Reminders

Participants clearly preferred an app that includes interactive elements enabling communication with health care professionals and peer-to-peer support. This interest in integrating social interaction and emotional support in mHealth tools aligns with previous studies, which found that both are crucial for engagement in all kinds of mHealth interventions [77,78]. Such features have been shown to foster feelings of support and connectedness, particularly when users perceive that someone has taken the time to send messages and engage with them [79]. Nevertheless, it indicates again that a blended therapy approach might be warranted to preserve the unique benefits of face-to-face communication [74].

Another required function was notifications and reminders. Both are generally seen as helpful for improving user engagement and adherence to mHealth interventions. However, it appears crucial that notifications are tailored to individual progress and specific user needs—for instance, in terms of their schedule and routines, behaviors and preferences—rather than providing generic or frequent alerts, which can become annoying or be ignored [73,80,81]. Furthermore, the reminders' language has been shown to play a role [80].

Reminders are not the only form of notifications, which might be worth implementing in an mHealth intervention. Preliminary evidence suggests that theory-driven trigger messages based on behavior change theories can have beneficial effects on user engagement by providing reinforcement and targeting motivation, self-efficacy, knowledge, and self-care [81].

RenderX

Personalization

Personalization emerged as a cross-cutting theme across multiple topics, particularly regarding design and functionalities. For instance, participants would like the app to provide customized content, such as a tailored introduction to and progression through the use of music. This is consistent with other research on mHealth interventions, which shows that personalized designs and functions lead to greater satisfaction, long-term adherence, and effectiveness [73,77,82,83]. Gosetto et al [82] described 4 dimensions of personalization of mHealth: users, system functionalities, information, and app properties. All these aspects were also mentioned by participants, either explicitly or implicitly, in the context of personalization.

Content: Scientific Foundation, Education, and Health Tracking

Regarding content, participants emphasized the importance of providing scientifically validated information to ensure the intervention's credibility and trustworthiness and, consequently, a reduction of stress. This suggests that participants viewed the app not only as a tool for using music for health but also as a means of transmitting medical and health education. Furthermore, clear instructions and tutorials on how to use the app and interpret the information were seen as crucial for facilitating usability. This finding aligns with previous literature underlining the importance of mHealth interventions with high standards of content quality, ensuring that information is not only accurate but also understandable and actionable (eg, [84]). Additionally, increasing parents' knowledge on essential aspects of preterm birth can improve their decision-making, which, in turn, affects maternal and infant health [40].

Thereby, to foster adherence to the intervention, it appears especially important to emphasize the positive effects of music therapy [19,52,85] and kangaroo care alone [14] on parents and preterm infants as well as the additional effects stemming from a combination of both [70,86].

Furthermore, incorporating a diary option was frequently mentioned as a valuable tool for parents. This might be explained by the positive impact of narrative diaries in the NICU, which has already been shown [87]. According to a systematic review, these diaries can "improve humanization, communication between NICU staff and parents, parents' coping, and closeness to their newborn" [87]. A diary as part of an mHealth intervention might have similar promising effects. Another advantage is that they can easily be integrated into existing routines, which, as mentioned above, might enhance an mHealth intervention's acceptance. Diaries are already implemented in many NICUs and could just be expanded by adding music and sounds next to pictures of the infants.

Sustainability and Long-Term Use

The concept of sustainable, long-term use emerged as another critical topic. Previous research indicates that music therapy generally has potential for long-term use and impact on preterm infants and their families, even after NICU discharge [70,88,89]. For instance, combining music with reading has been shown to improve language development in preterm infants at 2-3 years of age [89], and music became an integral part of their families' daily life even after supervised interventions ended [70].

Many participants indicated that the long-term use of mHealth interventions depends on the app's usability across different stages of the child's development. As mentioned earlier, personalization in the form of tailored, acutely relevant content, functions, and design might play a key role in long-term intervention adherence. Previous research supports the importance of personalized design, functions, and knowledge transfer and adds personal goals as crucial factors for long-term application of mHealth interventions [83].

Therefore, an mHealth intervention integrating music therapy elements, ongoing support, tailored information, personalization, and coaching is likely to enhance the intervention's sustainability, long-term use, and overall effectiveness.

Acceptance: Addressing Diverse User Needs, Updates, Data Security

Acceptance emerged as a recurring theme, with participants—in particular health care professionals—underscoring the importance of addressing the diverse needs of both parents and clinical staff, particularly given the time constraints faced by the latter. This demonstrates that a human-centered design is imperative, considering the perspectives and daily realities of both as well as the context of use from early on in the design process [45], thereby reinforcing the value of the ECOUTER approach's participatory principles. In addition, participants expressed the need for regular updates to ensure that the app content remains relevant and engaging. This is also reflected in their desire for continuous improvement and responsiveness to users' needs. Furthermore, data security was identified as a critical concern. Participants stressed that ensuring privacy and protection of personal health data would significantly influence their willingness to adopt and continue using the app. This aligns with existing literature on digital health adoption, which emphasizes privacy concerns as a considerable barrier to the widespread use of health technologies (eg, [79,90]). Interestingly, in other studies on digital interventions, this concern was not shared by patients or therapists [91], suggesting that perceived risks may vary depending on the type of data involved.

Strengths and Limitations

Given the increasing focus on family-centered and family-integrating care in neonatology, involving family members of preterm infants in developing this mHealth intervention appears crucial for ensuring their needs are met. At the same time, experts from a range of health care professions could contribute valuable expertise and insights into the needs of NICU staff and how a CMT-based intervention may be integrated into the dense and demanding setting of NICUs. Thus, including both groups of participants and the diversity of their roles is a clear strength of this study. Moreover, the large number of contributions, their level of detail and their diversity—reflecting the broad spectrum of perspectives—along with continuous coediting and iterative restructuring led to a comprehensive framework of user needs and preferences for a usable and acceptable mHealth intervention. Saturation was

XSL•FO
RenderX

assumed once no new input emerged, and participants confirmed that nothing more could be added. This demonstrates that following the ECOUTER approach was both meaningful and effective. Furthermore, as the approach is based on iterative feedback loops, it allowed us to conduct multiple rounds of participant engagement and to focus on purposeful sampling for the final round, specifically recruiting scientific advisory board members, experts, and parent representatives from premature infant organizations.

However, several limitations of this study should also be acknowledged, primarily related to the study sample. First, while the qualitative design and iterative ECOUTER-informed engagement enabled in-depth exploration and yielded convergent themes across multiple rounds of participant input, the overall sample size was small, which may limit the transferability of the findings. However, the ECOUTER approach facilitated sustained, reflective engagement and enhanced analytic depth, partially mitigating constraints typically associated with single focus group designs [48]. In addition, participants were purposefully selected to represent a range of relevant stakeholder perspectives (including parents, clinicians, music therapists, and psychologists), which strengthened the relevance of findings for intervention development but also resulted in a sample with a high overall educational level. As all participants had completed tertiary education, the perspectives of people with lower socioeconomic status and lower health literacy may be underrepresented, potentially limiting applicability to more socioeconomically diverse populations due to potential differences in information needs, comprehension, and access. Furthermore, participants were recruited from several countries; however, these countries are culturally comparable, and the study did not aim to examine or compare health care systems. While contextual differences may still have influenced individual perspectives, this relative cultural similarity supports thematic coherence. Nonetheless, these factors should be considered when interpreting the findings and applying them to the development of an mHealth intervention for parents.

Second, the questions posed during the focus groups were primarily formulated by FBH. Her professional background and experience as a music therapist in the NICU might have influenced them. However, the question guide was cocreated with other interdisciplinary members of the core research team, and all discussions were held and documented by several interdisciplinary researchers.

Third, this study adopted a real-world, pragmatic approach based on an online collaboration tool. Due to this and anonymization requirements, the contributions on the digital board could not always be attributed to individual participants. Meanwhile, the online format of focus groups may have limited spontaneous, dynamic discussions that are typically seen in in-person settings and are characteristic of group processes. Prior research suggests that virtual focus groups may hinder nuanced dialogues and the ability to pick up nonverbal communication cues (eg, [92,93]). However, these ambiguities were considered a trade-off in favor of the flexibility the online format offers in terms of time and location.

Finally, while stickers allowed participants to visually emphasize certain aspects of the mind map, this method may have created the impression of a consensus or dominant views. Items marked more frequently might be perceived as more important than they are, and it might have biased those prioritizing later. Despite this potential bias, the approach provided valuable insights into participants' priorities and highlighted the path for future developmental work.

Conclusion and Implications

To our knowledge, this is the first study that provides in-depth insights into the needs, expectations, and concerns of parents and health care professionals regarding a CMT-based mHealth intervention in neonatal care. The NICU—characterized by emotional intensity, parental vulnerability, and clinical pressure—requires particularly sensitive and well-integrated digital solutions. Findings from this study highlight the importance of a user-centered and participatory design approach, engaging diverse user groups, to respond to their individual needs and ensure emotional sensitivity as well as clinical acceptability in the NICU.

The results show that the proposed CMT-based mHealth intervention is seen as a meaningful complement to traditional CMT, which ensures wider access, promotes equity, and fosters parental engagement and empowerment in a situation often marked by helplessness. Key user needs toward the intervention include a simple and inclusive design, personalization, interaction possibilities with health care professionals and peers, and the integration into the daily realities of users. Addressing those needs is critical for the mHealth intervention's acceptance and effectiveness.

Findings from this study provide a unique, valuable foundation for developing and codesigning the intervention. Subsequently, following a UCD approach, the intervention will be tested for usability, feasibility, and effectiveness, with each research step followed by system refinements before advancing to the next step [42].

Acknowledgments

We would like to thank all the participants for sharing their insights, experiences, and wishes with us, which provided valuable guidance for the further development of our music therapy-based mobile health intervention.

Language editing support was provided by ChatGPT-4 and ChatGPT-5 (OpenAI). The tool was used exclusively to refine grammar and phrasing; all scientific content, data interpretation, and conclusions remain the authors' original work, and every AI-suggested change was critically reviewed and approved by all coauthors.

Abstract

Background: Assistant teachers play a central role in supporting children with autism spectrum disorder in United Arab Emirates inclusive classrooms. Despite this importance, no prior study has used validated observational instruments to systematically evaluate assistant teachers' competency profiles across classroom practice and parent interaction domains simultaneously in this cultural context.

Objective: This program evaluation study assessed the professional performance of assistant teachers supporting children with autism spectrum disorder, examining classroom instructional competencies and parental engagement behaviors within a single United Arab Emirates diploma training program.

Methods: A convergent mixed methods design was used. Ten assistant teachers who completed a national diploma training program were assessed by 3 independent expert evaluators across 50 site visits (n=25, 50% classroom observations; n=25, 50% parent meeting observations) conducted in January 2025 and March 2025. Tool 1 assessed 11 standardized classroom competency criteria, and tool 2 assessed 8 parent interaction criteria, both using a 5-point Likert scale. Mean scores were calculated by averaging all evaluator ratings across observation sessions per criterion. Internal consistency was assessed using the Guttman λ (λ=0.79 for tool 2). Formal interrater reliability was not computed; consensus-based resolution was used in cases in which evaluator ratings differed, which is acknowledged as a methodological limitation. Qualitative field notes were analyzed using the 6-phase thematic analysis by Braun and Clarke.

Results: Classroom performance means were 4.56 (SD 0.19; very high) in phase 1 (January 2025) and 4.55 (SD 0.23; very high) in phase 2 (March 2025). All teachers (10/10, 100%) achieved ceiling scores for daily living skill support and cultural adherence (mean 5.00, SD 0.00) across both phases. Safety and hygiene criteria scores were in the high range (mean 4.00, SD 0.00 to 4.10, SD 0.32). In parent interaction assessments (tool 2), the overall mean was 4.75 (SD 0.20; very high). The highest-ranked criteria were empathetic family treatment (mean 4.92, SD 0.28) and meeting preparation (mean 4.88, SD 0.33). The lowest-ranked criterion was clarity of structured communication (mean 4.48, SD 0.51; very high). Qualitative themes identified culturally responsive communication, emotional attunement, and individualized education plan–aligned practice. Repeated SD values of 0.00 and the absence of formal interrater reliability statistics are limitations that should be considered when interpreting these findings.

Conclusions: Within this program-specific evaluation, assistant teachers demonstrated consistently high professional competence. These preliminary findings suggest that diploma-based training can support culturally aligned and technically proficient inclusive practice. Targeted professional development in proactive safety and hygiene integration and structured individualized education plan–linked parent communication are recommended. Replication with larger, multi-institutional samples is required before broader conclusions can be drawn.

assistant teachers; autism spectrum disorder; inclusive education; mixed methods study; classroom observation; parent engagement; teacher competency; program evaluation; diploma training; special education; classroom practice; parent-teacher meetings; observational assessment; cultural responsiveness; professional development; individualized education plan–aligned practice; IEP-aligned practice; autism support

Introduction

Background and Rationale

Autism spectrum disorder (ASD) presents a heterogeneous constellation of behavioral, communicative, and social challenges requiring individualized and responsive educational approaches. In the United Arab Emirates (UAE), national policy has progressively mandated equitable access to inclusive education for all children with disabilities, yet the pedagogical workforce supporting this mandate remains underexamined. Assistant teachers serve as the primary point of daily contact between children with ASD and the broader educational environment, occupying a strategically critical but often underresearched role [1,2]. They collaborate with lead educators to implement individualized education plans (IEPs), manage behavior, provide adaptive learning support, and facilitate daily routine transitions.

Despite their centrality, assistant teachers are frequently absent from formal performance evaluation frameworks in the region. Prior research has focused predominantly on lead teachers or on Western educational contexts where cultural and organizational structures differ substantially from those in the UAE [3,4]. Recent work by Opoku et al [5] and Benson and Perepa [6] has begun to document the expanding roles and training needs of teaching assistants in Gulf Cooperation Council contexts; however, no study to date has applied validated observational instruments to assess competency profiles across both classroom practice and parent interaction domains simultaneously in this setting. The systemic dimension of inclusive education is also relevant: Mahmood et al [7] demonstrate that teacher and administrator support together shape the adaptation of students with special needs, underscoring that evaluating teacher competencies in isolation provides only a partial picture of inclusive practice quality.

Theoretical Framework: Culturally Responsive Pedagogy in the UAE Context

This study is informed by the framework of culturally responsive pedagogy (CRP), which holds that effective teaching requires active integration of students' and families' cultural values, linguistic practices, and community norms into instructional design and relational interactions [8,9]. Gay [8] identifies cultural competence, cultural communication, and inclusive curriculum as the 3 core dimensions of CRP, arguing that educators who embed cultural knowledge into practice produce stronger academic and social outcomes for culturally diverse learners. In the UAE context, CRP takes a distinctive form: assistant teachers are professionally expected to use Modern Standard Arabic (Fusha Arabic)—the formal, standardized register of Arabic used in education, religious practice, and official communication, distinct from regional colloquial dialects (*ammiyya*)—as the instructional medium; embody Islamic behavioral norms, including modest dress, respectful greetings (such as *As-salamu alaykum* ["Peace be upon you"]), and the integration of faith-based values into classroom routines; and serve as cultural mediators between school and family environments [10]. These expectations are not informal customs but formally incorporated into UAE educational policy [10] and into the diploma training program evaluated in this study. Ladson-Billings [9] argues that such culturally embedded practice is not supplementary but foundational to student belonging and learning efficacy, particularly for children with disabilities who are additionally vulnerable to social marginalization. This theoretical lens situates the study's findings within a broader international framework, enabling comparisons across culturally specific inclusive education contexts beyond the UAE.

Aims

This study was a program-specific evaluation, not a representative study of UAE assistant teachers broadly. It aimed to (1) document the overall and domain-specific professional performance of assistant teachers within 1 UAE diploma training program, (2) identify areas of consistent strength and relative development need within this sample, and (3) derive practice-based recommendations for training program improvement.

Three research questions guided the evaluation: (1) what were the overall and domain-specific professional performance levels of assistant teachers as assessed through structured observational tools? (2) How did assistant teachers demonstrate alignment with Emirati cultural and Islamic values, and what behavioral forms did this alignment take? (3) What practice-level gaps in safety, hygiene, and parent communication are indicated by these evaluation findings, and what training responses are appropriate?

Methods

Study Design

A convergent mixed methods design was used [11] combining structured quantitative observational ratings with concurrent qualitative field notes. Quantitative data provided standardized performance measurement across predefined criteria; qualitative data provided behavioral depth, contextual nuance, and interpretive triangulation. Both data streams were analyzed independently and subsequently integrated at the interpretation stage.

Observational data collection was conducted in January 2025 and March 2025 (phases 1 and 2, respectively) as part of a formal quality assurance evaluation initiated by the Zayed Authority for People of Determination in collaboration with the National Academy for Childhood Development. The diploma program itself had been developed and delivered over the

XSL•FO
RenderX

preceding years; this evaluation assessed graduates at 2 time points approximately 2 months apart.

Participants and Sampling

Participants were 10 assistant teachers who had recently completed the National Academy for Childhood Development's assistant teacher diploma program in early childhood education and were actively employed in settings serving children with ASD. Purposive sampling was used to select a theoretically homogeneous posttraining sample. The sample of 10 is appropriate for the intensive, multi-visit observational design used in which each participant was assessed across multiple sessions by 3 evaluators, yielding 50 total site visits. However, given that all participants were drawn from a single diploma program, these findings must be understood as program specific and not generalizable to UAE assistant teachers broadly. Three independent expert evaluators, each with formal special education qualifications and experience in ASD-inclusive settings, conducted all observations.

Instrumentation

Two purpose-built observational rubrics were developed and validated for this evaluation. Tool 1 assessed 11 standardized performance criteria covering classroom management, student supervision, transition monitoring, preparation of materials, daily living skill support, health and nutrition knowledge, safety and risk management, hygiene practices, emotional engagement, and cultural adherence. Tool 2 assessed 8 criteria for parent interaction: trust building, active listening and shared decision-making, meeting preparation, communication clarity, empathetic engagement, IEP-aligned guidance, professional communication style, and cultural sensitivity. The identical 11-criterion wording was used across both observation phases to ensure measurement consistency. Both instruments used a 5-point Likert scale (1="strongly disagree"; 5="strongly agree"). Content validity was established through review by a panel of 3 special education specialists. Internal consistency for tool 2 was estimated using the Guttman λ (λ=0.79), indicating acceptable reliability for small-sample educational research [12]. Tool 1 reliability was assessed using the same approach, yielding comparable internal consistency.

Data Collection Procedure

A total of 50 site visits were conducted: 25 (50%) classroom observation sessions and 25 (50%) parent meeting observation sessions. Each session was observed in its entirety. Observations were unannounced (ie, teachers were not informed of the specific evaluation criteria in advance) to reduce social desirability bias. Evaluators independently completed quantitative rubric ratings and open-ended qualitative field notes after each session.

Data Analysis

Quantitative Analysis

Mean scores were calculated by averaging all evaluator ratings across all observation sessions per criterion (ie, the unit of analysis was individual observation sessions aggregated across teachers and evaluators). SDs reflect variability across these aggregated ratings. Performance was classified using the range-based framework in Table 1. Three criteria yielded an SD value of 0.00, indicating complete uniformity across all evaluators and sessions; while theoretically possible for behaviorally anchored competencies, this pattern is unusual in applied educational research and may alternatively reflect limited rubric sensitivity, observer-related score compression, or reactivity effects from being observed, as discussed further in the Discussion section. The substantially higher SD for criterion 6 in phase 2 (1.15) is examined as a criterion-specific finding in the Results and Discussion sections. Formal interrater reliability (intraclass correlation coefficient [ICC] or κ) was not computed: evaluator ratings were averaged per criterion per session, and discrepancies were resolved through structured consensus discussion. The absence of a formal agreement statistic is acknowledged as a methodological limitation that affects the interpretive confidence that can be placed in individual criterion scores.

Table . Performance level classification based on mean score ranges.

Score range	Performance level
1.00 to <1.80	Very low
1.80 to <2.60	Low
2.60 to <3.40	Moderate
3.40 to <4.20	High
4.20 to 5.00	Very high

Qualitative Analysis

Field notes were analyzed using the 6-phase thematic framework by Braun and Clarke [13]: (1) data familiarization, (2) initial code generation, (3) theme development, (4) theme review, (5) theme definition, and (6) report production. Triangulation between quantitative and qualitative datasets was conducted to assess convergence and identify discrepancies.

Ethical Considerations

This study constituted a formal institutional performance evaluation conducted as part of a structured quality-assurance process within an established professional training program. It did not involve recruitment of human research participants, experimental intervention, or collection of sensitive personal data requiring ethics board oversight. The evaluation was initiated and authorized by the Zayed Higher Organization for People of Determination and the National Academy for Child

XSL•FO
RenderX

Development under their respective institutional quality-assurance mandates. All participating assistant teachers provided institutional consent through their professional program enrollment agreements. No data pertaining to children, families, or identifiable individuals were collected or reported. In accordance with the research ethics policy of Emirates Scholar Center for Research & Studies, Abu Dhabi—which stipulates that internal program evaluations and posttraining competency assessments conducted within institutional quality-assurance frameworks are exempt from formal ethics board review—independent ethics approval was not sought for this evaluation. All data were handled confidentially and reported in aggregate form without individual identification.

Results

Performance Classification Framework

Table 1 presents the scoring rubric used to classify all performance means.

Classroom Observations: Phase 1 (January 2025; Tool 1)

Table 2 presents mean scores and SDs for the 11 classroom performance criteria in phase 1. The overall mean was 4.56 (SD 0.19; very high). All teachers (10/10, 100%) achieved the maximum score for criteria 3 (transition monitoring), 5 (daily living skill support), and 11 (cultural adherence; mean 5.00, SD 0.00 for each). All teachers (10/10, 100%) scored in the high range for criteria 7 (safety knowledge), 8 (hazard-free environment), and 9 (hygiene; mean 4.00, SD 0.00; mean 4.00, SD 0.00; and mean 4.10, SD 0.32, respectively). The items with an SD of 0.00 indicate complete uniformity across all evaluators and sessions; possible interpretations are discussed in the Discussion section.

Table . Mean scores and SDs for classroom performance—phase 1 (January 2025).

Criterion number	Criterion description	Score (1-5), mean (SD)[a]	Rank	Rating
1	Assisted in classroom management to ensure a responsive learning environment.	4.60 (0.52)	7	Very high
2	Supervised students during structured activities (eg, reading, assignments, and motor therapy).	4.50 (0.53)	9	Very high
3	Closely monitored students' entry to and exit from the classroom.	5.00 (0.00)[b]	1	Very high
4	Prepared and effectively used classroom tools and resources (eg, audiovisual aids).	4.80 (0.42)	4	Very high
5	Supported students in daily living skills (eg, eating, dressing, and toileting).	5.00 (0.00)[b]	1	Very high
6	Demonstrated knowledge in health and nutrition relevant to child development.	4.75 (0.46)	5	Very high
7	Displayed knowledge of safety and security procedures relevant to children.	4.00 (0.00)[b]	10	High
8	Maintained a physically safe learning environment based on best practices.	4.00 (0.00)[b]	10	High
9	Ensured classroom hygiene and sanitation to prevent infectious diseases.	4.10 (0.32)	9	High
10	Demonstrated enthusiasm and emotional presence while interacting with children.	4.70 (0.48)	6	Very high
11	Adhered to Emirati cultural values, customs, and Islamic principles at all times.	5.00 (0.00)[b]	1	Very high

[a]Overall mean 4.56 (SD 0.19; very high).

[b]SD of 0.00 indicates complete evaluator and session uniformity; possible interpretations include genuine ceiling-level performance, observer-related score compression, or limited rubric sensitivity at the upper end of the scale (see the Discussion section).

Classroom Observations: Phase 2 (March 2025; Tool 1)

Table 3 presents phase 2 data using the same standardized criteria. The overall mean was 4.55 (SD 0.23; very high), virtually identical to that of phase 1 (mean 4.56, SD 0.19). All teachers (10/10, 100%) again achieved ceiling scores for criteria 5 and 11 (mean 5.00, SD 0.00 each). Safety and hygiene criteria (7, 8, and 9) remained in the high range (mean 4.00, SD 0.00 in all cases), unchanged from phase 1. Criterion 6 (health and nutrition knowledge) showed the most substantive phase 2 change: the mean decreased from 4.75 (SD 0.46) to 4.33 (SD 1.15) but with a markedly higher SD. This criterion-specific increase in variability—against the background of otherwise compressed SDs across the dataset—is discussed separately in the Discussion section as a domain-specific finding rather than a general measurement issue.

Table . Mean scores and SDs for classroom performance—phase 2 (March 2025).

Criterion number	Criterion description	Score (1-5), mean (SD)[a]	Rank	Rating
1	Assisted in classroom management to ensure a responsive learning environment.	4.70 (0.48)	4	Very high
2	Supervised students during structured activities (eg, reading, assignments, and motor therapy).	4.70 (0.48)	4	Very high
3	Closely monitored students' entry to and exit from the classroom.	4.60 (0.84)	7	Very high
4	Prepared and effectively used classroom tools and resources (eg, audiovisual aids).	4.80 (0.42)	3	Very high
5	Supported students in daily living skills (eg, eating, dressing, and toileting).	5.00 (0.00)[b]	1	Very high
6	Demonstrated knowledge in health and nutrition relevant to child development.	4.33 (1.15)[c]	8	Very high
7	Displayed knowledge of safety and security procedures relevant to children.	4.00 (0.00)[b]	9	High
8	Maintained a physically safe learning environment based on best practices.	4.00 (0.00)[b]	9	High
9	Ensured classroom hygiene and sanitation to prevent infectious diseases.	4.00 (0.00)[b]	9	High
10	Demonstrated enthusiasm and emotional presence while interacting with children.	4.70 (0.48)	4	Very high
11	Adhered to Emirati cultural values, customs, and Islamic principles at all times.	5.00 (0.00)[b]	1	Very high

[a]Overall mean 4.55 (SD 0.23; very high).

[b]SD of 0.00 indicates complete evaluator and session uniformity; possible interpretations include genuine ceiling-level performance, observer-related score compression, or limited rubric sensitivity at the upper end of the scale (see the Discussion section).

[c]SD of 1.15 indicates substantially higher interindividual variability in health and nutrition knowledge application; this criterion-specific finding is discussed in the Discussion section.

Comparative Analysis: Phases 1 and 2

The near-identical overall means across phases (4.56, SD 0.19 vs 4.55, SD 0.23) indicate performance stability at the aggregate level over the 2-month interval. The identical domain strength pattern (daily living skills and cultural adherence) and development pattern (safety and hygiene) across both phases confirms that these represent consistent rather than transient characteristics within this sample. The sole criterion-level cross-phase difference was the increased SD for criterion 6 in phase 2, which is examined further below.

Qualitative Findings: Classroom Observations

Table 4 presents the key behavioral patterns identified through thematic analysis of classroom field notes. Modern Standard Arabic (Fusha Arabic)—the formal register of Arabic used in UAE education and official discourse, distinct from colloquial spoken dialects—was universally used for instruction, reflecting the program's explicit linguistic and cultural expectations.

XSL•FO
RenderX

Table . Key observed behavioral patterns during classroom visits—thematic summary.

Criterion number	Competency area	Key observed practices
1	Classroom management	Gave clear instructions before each activity, used a calm tone with visual cues, and divided the class into small groups to reduce distraction.
2	Supervision of activities	Maintained constant presence, used varied materials (cards, blocks, and sensory tools), and coordinated effectively with the lead teacher.
3	Attendance and transitions	Strictly adhered to entry and exit procedures, accurately documented attendance, and guided children to their belongings in an orderly manner.
4	Preparation of materials	Used age- and ability-appropriate audiovisual tools and prepared all materials before each session.
5	Daily living skill support	Encouraged self-help behaviors (eating and dressing) through verbal reinforcement and provided individualized bathroom guidance respecting developmental level.
6	Health and nutrition awareness	Communicated handwashing advice using age-appropriate language and explained the nutritional value of foods during mealtime.
7	Safety knowledge	Avoided hazardous tools, prompted children to sit safely, and demonstrated basic environmental risk awareness during transitions.
8	Hazard-free environment	Organized pathways, maintained visual supervision, and used child-sized furniture with safe spacing between activity areas.
9	Hygiene and sanitation	Disinfected tables before activities, prompted handwashing multiple times daily, and cleaned tools and materials after use.
10	Emotional engagement	Maintained consistent eye contact and warm demeanor and used an encouraging tone and expressive gestures.
11	Cultural and religious sensitivity	Delivered instructions in Modern Standard Arabic (Fusha Arabic), promoted Islamic values and etiquette, and wore modest attire aligned with UAE[a] professional norms.

[a]UAE: United Arab Emirates.

Qualitative data largely corroborated the quantitative profile. Assistant teachers consistently demonstrated culturally aligned, emotionally attuned, and instructionally organized practice. Regarding safety and hygiene, evaluators noted that, although basic safety behaviors were present, they appeared reactive rather than proactively embedded within structured daily routines. This behavioral distinction is not fully captured by the Likert scale and has direct implications for training design.

Parent Interaction Observations (Tool 2)

Table 5 presents mean scores for the 8 parent interaction competencies. The overall mean was 4.75 (SD 0.20; very high). All teachers (10/10, 100%) scored in the very high range across all 8 criteria. The highest-ranked criteria were empathetic family treatment (mean 4.92, SD 0.28; criterion 5), meeting preparation (mean 4.88, SD 0.33; criterion 3), and cultural respect (mean 4.88, SD 0.33; criterion 8). Clarity of structured communication (criterion 4; mean 4.48, SD 0.51) and IEP-aligned guidance (criterion 6; mean 4.52, SD 0.51) were the lowest-ranked criteria, both still classified as very high, representing the relative lower bound of an otherwise uniformly strong parent interaction profile.

XSL•FO
RenderX

Table . Mean scores and SDs for parent interaction competencies—tool 2.

Criterion number	Competency area	Score (1-5), mean (SD)[a]	Rank	Rating
1	Building relationships with parents based on mutual trust and cooperation	4.76 (0.44)	4	Very high
2	Listening to parents and involving them in decisions about child safety, health, and education	4.76 (0.44)	4	Very high
3	Adequate preparation for parent meetings and effective time management	4.88 (0.33)	2	Very high
4	Clarity and professionalism in delivering useful information and responding to questions	4.48 (0.51)	8	Very high
5	Treating all families fairly and empathetically, with sensitivity to their psychological context	4.92 (0.28)	1	Very high
6	Providing guidance based on the child's individualized academic and behavioral plan	4.52 (0.51)	7	Very high
7	Effective communication using positive body language and a professional demeanor	4.76 (0.44)	4	Very high
8	Respect for Emirati cultural values and Islamic principles at all times	4.88 (0.33)	2	Very high

[a]Overall mean 4.75 (SD 0.20; very high).

Qualitative Findings: Parent Interaction

Table 6 presents behavioral themes from parent meeting observations.

Trust building, cultural respect, and preparedness were pervasive across all participants. The use of Modern Standard Arabic, respectful Islamic greetings, and professional attire aligned with UAE norms were consistent across observations. Regarding communication clarity (criterion 4), evaluators noted that 40% (4/10) of the teachers across multiple sessions showed difficulty organizing complex verbal information in a sequential, parent-accessible manner when presenting multicomponent student progress data. This was a recurring qualitative theme that was consistent with the lowest quantitative ranking for this criterion.

XSL•FO
RenderX

Table . Key behavioral observations during parent meetings—thematic summary.

Criterion number	Competency area	Key observed practices
1	Trust and rapport	Demonstrated warm, approachable demeanor and created an atmosphere of comfort and confidence for parents.
2	Active listening and shared decision-making	Showed strong listening skills, responded constructively to parental concerns, and involved families in discussions about child development.
3	Preparation and time management	Arrived prepared with individualized plans and materials and communicated the meeting structure clearly.
4	Clarity of communication	The information was accurate and aligned with child needs; occasional inconsistencies in verbal organization were observed across cases.
5	Fairness, empathy, and family sensitivity	Treated all families with fairness and calm reassurance and was sensitive to the emotional state of parents.
6	IEP[a]-aligned guidance	Offered concrete, actionable guidance drawn from the student's academic and behavioral framework and linked recommendations to home and school contexts.
7	Professional communication and body language	Maintained professional posture, eye contact, and tone; nonverbal cues complemented verbal explanations.
8	Cultural and religious sensitivity	Used Modern Standard Arabic and respectful greetings, avoided culturally inappropriate behaviors, and their professional appearance aligned with UAE[b] norms.

[a]IEP: individualized education plan.

[b]UAE: United Arab Emirates.

Discussion

Principal Findings

This program-specific evaluation found that assistant teachers trained through 1 UAE diploma program demonstrated consistently high professional competence across classroom and parent interaction domains. Overall classroom means were 4.56 (SD 0.19; phase 1) and 4.55 (SD 0.23; phase 2), and the parent interaction mean was 4.75 (SD 0.20), all classified as very high ratings. Two criteria—daily living skill support and cultural and Islamic adherence—reached the maximum score in both phases. Safety, hygiene, and structured parent communication occupied the lower end of the performance distribution, classified as high, high, and very high, respectively. These findings are best understood as an initial evaluation of one specific professional preparation pathway; they should not be interpreted as representative of UAE assistant teachers generally.

Measurement Considerations: SD of 0.00, Interrater Reliability, and Score Interpretation

The repeated findings of an SD of 0.00 across multiple criteria and evaluator sessions merit more than a brief acknowledgment. At least 3 interpretations must be considered. First, these values may reflect genuine ceiling-level uniformity for behaviors that the training program explicitly and systematically cultivated—particularly cultural adherence and daily living skill support—where the program's clear behavioral expectations may have produced genuine compliance across all assessed teachers. Second, the pattern of an SD of 0.00 may reflect observer-related score compression: evaluators aware of the program's cultural expectations may have rated cultural and routine behaviors at ceiling as a matter of professional expectation rather than independent behavioral discrimination. This is a form of observer-related scoring bias that cannot be excluded in the absence of formal interrater reliability testing. Third, the rubric itself may have limited sensitivity at the high end of the performance scale, producing floor effects at ceiling that compress discriminant variance regardless of actual performance differences.

The absence of formal interrater reliability statistics (ICC or κ) is the most significant methodological limitation of this study. Because quantitative scores were the product of 3 evaluators whose ratings were averaged rather than independently verified for agreement, it is not possible to determine with confidence whether high means reflect genuine uniformity of performance or shared evaluator assumptions. The consensus-based discrepancy resolution used in this study reduced obvious discrepancies but did not quantify the extent of agreement. Future evaluations must incorporate ICC or weighted κ statistics to establish measurement robustness. These findings should be interpreted as indicative rather than confirmatory, acknowledging this uncertainty.

XSL•FO
RenderX

Regarding the reactivity of being observed, even in unannounced observations, the presence of an expert evaluator may have elevated performance, particularly in culturally salient domains where social conformity expectations are strong. This form of observer-related reactivity is well documented in educational observational research [14] and may have contributed to the ceiling-level scores observed for cultural adherence criteria across all participants.

Criterion 6 (Health and Nutrition; Phase 2): A Domain-Specific Finding

The substantially elevated SD for criterion 6 in phase 2 (1.15 vs 0.46 in phase 1) requires specific interpretation rather than treatment as a general measurement irregularity. This criterion uniquely combines applied nutritional knowledge with real-time classroom communication skills—a domain that may be more susceptible to individual variation in prior professional experience, health literacy background, and deployment context than procedurally anchored criteria such as transition monitoring or cultural adherence. The wide variability in phase 2 suggests that, among the 10 participants, some had developed sophisticated practical nutrition communication skills whereas others had not despite similar training exposure. This heterogeneity has specific implications: health and nutrition content in future training cohorts may benefit from differentiated instruction or competency-based checkpoints to ensure baseline consistency rather than uniform delivery.

Performance Stability and Training Program Evidence

The near-identical overall means across the 2-month interval are consistent with the view that the diploma program produces competencies that are retained rather than decaying over short-term posttraining periods, as predicted by models of practice-based professional learning [15]. However, this stability in aggregate scores must be interpreted cautiously given the measurement limitations noted above, and it does not confirm that the program is responsible for observed competencies as no pretraining comparison data are available. Evidence-based professional development models integrating autism-specific content with coaching and peer learning are associated with the most robust competency gains [16,17], and the apparent stability of this program's outcomes is encouraging as a preliminary finding pending more rigorous investigation.

CRP: Theory and Practice

The consistent ceiling-level scores for cultural and Islamic value adherence across both observation phases and both evaluation domains provide behavioral evidence for the theoretical proposition by Gay [8] that cultural competence, when systematically embedded in teacher preparation, is reliably acquirable. The observed behaviors—Modern Standard Arabic instruction, modest attire, Islamic greeting conventions, and faith-integrated classroom routines—are precisely the behavioral dimensions of CRP that Ladson-Billings [9] identifies as foundational to culturally inclusive practice. Massouti et al [10] document that UAE inclusive education policy explicitly mandates these practices, suggesting that the evaluated diploma program successfully operationalized national policy expectations at the classroom behavioral level. The contribution of this finding for international readers lies in demonstrating that a culturally specific form of CRP can be formally assessed through observational rubrics, offering a methodological model for evaluating cultural competence in other non-Western inclusive education contexts [18].

Safety, Hygiene, and Reactive-to-Proactive Training Design

The consistent high rating classification for safety and hygiene criteria across both phases, combined with qualitative findings documenting reactive rather than proactively integrated safety behaviors, points to a specific training gap: not in awareness but in procedural habituation. This distinction matters for training design: awareness-level interventions (information delivery and safety briefings) are insufficient if the goal is automatic, routine-embedded safety practice. There is evidence from analogous professional development contexts suggesting that behavioral rehearsal, scenario-based simulation, and routine-embedding protocols are more effective than didactic instruction for achieving procedural automaticity [19]. The uniform SD of 0.00 for safety items also raises the possibility that the current rubric may not discriminate adequately between reactive and proactive safety integration, suggesting that future instrument development should include behavioral indicators specifically targeting routine embeddedness.

Parent Communication and IEP Translation

Communication clarity (mean 4.48, SD 0.51; very high; lowest ranked) and IEP-aligned guidance (mean 4.52, SD 0.51; very high; second-lowest ranked) occupied the lower end of the parent interaction profile. These criteria are conceptually distinct from the empathy and cultural responsiveness in which assistant teachers excelled: translating technical IEP data into accessible, sequential verbal guidance for parents requires meta-cognitive and expressive language competencies that are not routinely developed through general training. Structured communication tools—including scripted meeting frameworks, standardized IEP progress summary templates, and bilingual communication resources—represent evidence-supported interventions for this domain [20]. Mahmood et al [7] emphasize that administrative support structures also shape family engagement quality, suggesting that training-level interventions should be complemented by institutional frameworks that provide assistant teachers with preparation time, parent communication templates, and supervisory guidance.

Scope and Generalizability

It bears repeating that these findings are derived from 10 assistant teachers drawn from a single diploma training program operating within a specific institutional partnership. The conclusions that can legitimately be drawn are as follows: (1) within this program, assistant teachers demonstrated high and stable competency profiles; (2) the evaluated program appears to successfully develop cultural competence and daily living skill support to ceiling level; and (3) safety, hygiene, and structured parent communication represent areas for targeted training improvement within this program. Claims about UAE assistant teacher performance broadly or about national policy

XSL•FO
RenderX

implications exceed what this evidence can support and have been deliberately moderated in this study.

Recommendations

The following practice-based recommendations are offered for this program's future development:

- Develop safety and hygiene training modules incorporating behavioral rehearsal, scenario-based simulation, and routine-embedding protocols to promote proactive rather than reactive safety integration.
- Implement structured parent communication training using scripted meeting frameworks, standardized IEP progress summary templates, and bilingual communication resources complemented by institutional preparation time structures.
- Incorporate formal interrater reliability assessments (ICC or weighted κ) into all future observational evaluation protocols to strengthen measurement rigor.
- Revise the observational rubric to include behavioral indicators that discriminate between reactive and proactive safety integration, addressing the possible ceiling and sensitivity limitation identified.
- Consider differentiated instruction or competency checkpoints for health and nutrition content to address the interindividual heterogeneity identified in phase 2.

Limitations

This study has several important limitations. First, the sample (N=10) drawn from a single diploma program substantially restricts generalizability; the findings describe this program's graduates and should not be extrapolated to UAE assistant teachers broadly. Second, formal interrater reliability (ICC or κ) was not computed; the consensus-based resolution method used is insufficient to confirm score stability, and this materially limits confidence in individual criterion means. Third, the repeated SD values of 0.00 may reflect observer-related score compression, reactivity to observation, or limited rubric sensitivity rather than true performance uniformity. Fourth, the absence of pretraining comparison data means that no causal claims about training program effects can be made. Fifth, the study did not assess child developmental outcomes, precluding any inference about the relationship between teacher competence and student progress. Sixth, the 2-month observational window is insufficient to characterize longer-term performance trajectories.

Future Research Directions

Future studies should (1) replicate this evaluation with larger multi-institutional samples across different UAE emirates to enable comparative analysis and normative data development, (2) incorporate formal ICC or weighted κ statistics and pretest-posttest training designs to strengthen methodological rigor, (3) examine the relationship between assistant teacher competency profiles and child developmental outcomes, (4) investigate the specific mechanisms through which health and nutrition knowledge variability (criterion 6) develops differentially across training cohorts, and (5) evaluate the effectiveness of the targeted training interventions recommended above through controlled or quasi-experimental designs.

Conclusions

This program evaluation provides preliminary evidence that assistant teachers trained through 1 UAE diploma program demonstrate consistently high professional competence across classroom and parent interaction domains, with particular strengths in culturally responsive practice and daily living skill support. Two practice-level gaps—proactive safety and hygiene integration and structured IEP-linked parent communication—emerged as priority areas for training improvement within this program.

These findings should be understood as preliminary and program specific. They suggest that structured, culturally grounded diploma program training can support high professional performance in assistant teachers working with children with ASD in the UAE context, but replication with larger, multi-institutional samples incorporating formal interrater reliability measures is required before broader claims can be made. The measurement limitations of this study—particularly the absence of ICC statistics and the interpretive uncertainty associated with repeated SD values of 0.00—must be addressed in future evaluations.

Abstract

Background: Sudden and unexpected infant death is a leading cause of postneonatal death in the United States. Following recommended infant care practices such as safe sleep and breastfeeding reduces the risk of sudden and unexpected infant death. Parents use social media to help them make decisions about infant care practices.

Objective: The objective of our qualitative study was to explore mothers' perspectives on the acceptability of Facebook private groups for providing education on infant care practices.

Methods: We conducted a descriptive qualitative study that recruited a purposeful sample of pregnant persons and mothers who recently gave birth; all were clients of the Special Supplemental Nutrition Program for Women, Infants, and Children in 1 of 2 states. We conducted in-depth interviews that were analyzed inductively through a systematic, iterative process using an interview guide. We asked participants about their perspectives regarding the use of Facebook private groups for learning about infant care practices, including sleep practices and breastfeeding. Data were collected until data sufficiency was reached.

Results: Of the 22 participants, 13 (59.1%) were Special Supplemental Nutrition Program for Women, Infants, and Children clients from Rhode Island, and 9 (40.9%) were from Virginia. While participants' use of Facebook in general varied, all either used Facebook private groups to obtain infant care practice guidance about safe sleep and breastfeeding or liked the idea of using specifically Facebook private groups to disseminate this information to pregnant persons and new parents. Participants reported using Facebook private groups for three main purposes: (1) information seeking, (2) the experience of engaging with Facebook private groups, and (3) social connectedness.

Conclusions: Facebook private groups were endorsed by the participants for providing mothers with information about infant care practices. Participants outlined their reasons for and experience with the use of Facebook private groups, which can inform effective use of the platform for educational interventions.

KEYWORDS

social media; parenting; safe sleep; breastfeeding; qualitative; health behaviors

Introduction

Sudden and unexpected infant death (SUID), which includes sudden infant death syndrome, accidental suffocation and strangulation in bed, and ill-defined deaths, is a leading cause of infant mortality between 1 month and 1 year of age, accounting for approximately 3700 annual deaths in the United States in 2022 [1]. Black infants are more than twice as likely to die of SUID when compared to non-Hispanic White infants, and poverty remains an important risk factor [2]. Safe sleep practices are the only known way to protect against SUID. These practices include placing infants to sleep supine on a separate, firm, flat surface with no loose blankets or objects and room-sharing without bed-sharing. Despite widespread public

XSL•FO
RenderX

health efforts to educate families on safe sleep practices and breastfeeding—behaviors that are crucial in reducing these deaths—the SUID rate in the United States has remained largely unchanged for over 20 years and may even be increasing most recently [3].

Parental decisions regarding sleep practices and breastfeeding are not based on knowledge of recommended practices from health care providers or other public health sources alone. Instead, mothers base many of their decisions about infant sleep and breastfeeding on information and advice from their social networks and increasingly on advice "crowdsourced" from others on the internet and/or social media [4]. Previous studies have shown that mothers want to weigh options for themselves, often trusting experiential advice from "people like me" more than evidence-based recommendations [5]. Consequently, social media now plays an important role in parenting decisions [6,7]. A recent study using 2021 Pew Research Center data found that the most popular social media platforms used by parents in the United States were YouTube (88%) and Facebook (79%) [8]. Mothers were especially likely to use Facebook, and 83% of the mothers who reported using Facebook did so daily [8].

Facebook private groups are communities people join based on common interests. They require moderator approval to view and participate in conversations. There are thousands of Facebook private groups for new or expectant parents based on city or neighborhood, profession, shared interests, or due dates. Facebook private groups have the option of having a moderator who can approve and remove posts and turn comments on or off. The moderators' degree of expertise and active moderation vary widely across groups. Given the nearly ubiquitous use of social media to guide parenting practices and the popularity of Facebook among mothers, we hypothesized that Facebook private groups could be leveraged to improve safe sleep and breastfeeding practices by creating large networks to promote safer norms for mothers with young infants. Thus, the objective of our qualitative study was to explore mothers' perspectives on the acceptability of Facebook private groups for providing education on infant care practices to inform the development of an intervention using this approach.

Methods

Design

We conducted a descriptive qualitative study [9,10] using a purposeful sample of pregnant persons and mothers with young infants to understand their perspectives on using Facebook private groups for education focused on safe sleep practices and breastfeeding. Understanding our target participant experience with Facebook private groups was the vital first step to developing an effective intervention using Facebook private groups to increase safe sleep behaviors and breastfeeding rates.

Ethical Considerations

Boston University served as the data coordinating center for this study, and their institutional review board deemed this study exempt (H-41548). The University of Virginia (2675), Columbia University Irving Medical Center (AAAT8775), and Washington University in St. Louis (202108141) participated in analysis of deidentified data, with the latter two also deeming the study exempt from review. Participants were provided with an information sheet, and all questions were answered by Boston University staff. Verbal consent was obtained prior to study enrollment. All participants received US $50 gift cards for taking part. Interviewees were assigned a participant number, and no personal identifying information was included in stored or analyzed transcriptions.

Sample

Clients of the Special Supplemental Nutrition Program for Women, Infants, and Children (WIC) who were pregnant or who recently gave birth were invited to participate in the study. All participants were at 27 weeks or more of gestation or had an infant younger than 6 months of age at the time of eligibility screening as they would have recent experience with using social media for information about infant care practices. To be eligible, participants also needed to be English speaking and own or have daily access to a Wi-Fi– or data-capable device on which they accessed social media. Participants did not need to use social media regularly or use Facebook to take part. Potential participants were excluded if they did not live or expect to live with their infant after birth or if the infant had or was expected to have a diagnosis that would impact infant care practices in a manner not compatible with study goals, including rare contraindications to breastfeeding or supine sleeping, such as use of medications contraindicated in breastfeeding, maternal HIV, or known spina bifida. Given the sensitive nature of these conditions, potential participants were asked whether their health care providers had advised that there was a contraindication to either practice rather than providing an exhaustive list of possible conditions. These eligibility criteria matched the criteria we intended to use in the larger intervention study.

WIC is an income-based program in the United States that provides supplemental nutrition vouchers for those who are pregnant or have dependents aged 5 years and under. WIC clients were chosen because the focus of our educational intervention was families who experience higher rates of SUID (eg, families who identified as being in a racial or ethnic minority group and/or with low income [11]). To be WIC eligible, one's gross income must be at or below 185% of the US Poverty Guidelines [12]; thus, WIC eligibility is an easily verifiable proxy for income that does not depend on self-report. Our goal was to develop an educational intervention for clients from WIC sites nationally to decrease SUID risk factors and increase protective factors, including breastfeeding, in this population. We chose qualitative methods to better understand the participant experience with Facebook private groups as this source of information was vital to aid in the development of the intervention.

QR codes with links to eligibility surveys were available in WIC offices via flyers, so they were available to all clients. Those who completed the survey and were eligible were contacted by study staff to complete the informed consent process and schedule interviews. All interested eligible participants who responded to scheduling calls took part.

Interview Guide Development

The topics for the interview guide were developed based on literature reviews of studies using social media groups for medical interventions and studies looking at maternal decision-making on infant care practices. The team also looked at existing new parent Facebook private groups for common topics. The topic guide was piloted and refined as the interviews continued to ensure that intended topics were addressed (Multimedia Appendix 1).

Data Collection

We conducted in-depth semistructured interviews through videoconference from July 21, 2022, to February 1, 2023. Interviews were conducted in English by 2 trained interviewers (KB and CR). We used an interview guide asking participants about their perspectives regarding the use of Facebook private groups for learning about infant care practices, including infant sleep practices and breastfeeding. We used prompts to learn about any experiences they had with Facebook private groups, their thoughts about using the platform, and the trustworthiness of the information they received in such groups. Interviews lasted 30 to 60 minutes and were audiotaped and transcribed verbatim. Basic demographic and health data were collected during the consent process. Interviews were conducted until sufficient data were collected for the purposes of this study [13].

Data Analysis

We analyzed data through a systematic, iterative process of data collection and analysis to inductively create categories and then themes. Each transcript underwent multiple reviews by 2 investigators (ERC and RFC), who performed the early readings and initial and iterative coding followed by theme development and creation of a codebook. The other investigators were provided with the codebook and several transcripts to review as we developed iterations of the codebook based on ongoing conversations about the findings to reach consensus [14]. The Dedoose software (SocioCultural Research Consultants) supported the organization of the analytic process [15].

Results

Overview

We conducted 22 interviews with 13 (59.1%) WIC clients from Rhode Island and 9 (40.9%) from Virginia. The median age of participants was 28.5 (IQR 23-32) years; 90.9% (n=20) of the participants identified as female, 36.4% (n=8) identified as non-Hispanic White individuals, 27.3% (n=6) identified as non-Hispanic Black or African American individuals, and 31.8% (n=7) identified as Hispanic; and 22.7% (n=5) were pregnant with their first child at the time of the interview (Table 1). A total of 4.5% (n=1) of the participants identified as nonbinary. While participants' use of Facebook as a social media platform varied widely, all either used Facebook private groups to obtain safe sleep and breastfeeding information or liked the idea of specifically using Facebook private groups to disseminate this information to pregnant persons and new parents. They described a range of moderation practices in groups in which they were members, including moderators with expertise in topic areas and community volunteers. Participants reported using Facebook private groups for three main purposes: (1) information seeking, (2) the experience of engaging with Facebook private groups, and (3) social connectedness (Table 2). Illustrative quotes from each theme and subtheme can be found in Table 2.

Table . Representative quotes from participants illustrating major themes and subthemes.

Themes and subthemes	Illustrative quotes
Information seeking	
Information quality and trustworthiness	• "I like to look at the comments [to decide if I trust something]. I like to see if anyone else has tried it already. That's why I realize I have to be on active Facebook groups and not just robots because I would want it to be where I see like if 100 moms tell me this works, I'm willing to try it....But I need to see that someone else was willing to give it a chance." [Quote 1; participant 17] • "I think Facebook is great because my husband uses Facebook...I used it the whole time I was pregnant for the groups of course. Much more easier to communicate with the different types of women who've been through similar situation like I have, and the security was a lot more trustworthy compared to Instagram who had a lot more bots from what I've noticed." [Quote 2; participant 17]
Accessibility of information	• "When I need a question, boom. Nobody has lives anymore, but that's not just pregnant people, that's people in general. So you can get a pretty quick response." [Quote 3; participant 12] • "Which is why I like Facebook groups because then you can go through and see the old posts and be like okay this is what I need right now. I don't want to go searching through the 15,000 pages of pamphlets that I have. Here's the information I need to know without a random Googling and having to try to trust what's there." [Quote 4; participant 20] • "Yes, where I did have to wait to be invited by one of the admins. It was very helpful because obviously there's like 30 or 40 of them. So it was very quick, and they asked relevant questions to make sure it wasn't just someone random trying to join in." [Quote 5; participant 17] • "It's good because everybody has a Facebook it's more like a nation-wide thing as to where if you do need the information it's easily found just by looking up certain groups." [Quote 6; participant 37]
Specific topics sought	• "I most got tips on how to prepare for breastfeeding and how to prepare myself when even breastfeeding does not work. It was a lot more better than truthfully what I got from my military hospital. So it gave me a bit more experience and I knew it was being done right because I've had a lot of people come and tell me this must not be your first child because you know how to properly hold the child because like most first time moms don't. I got a lot of great tips from that." [Quote 7; participant 17]
Experience of engaging with a Facebook group	
Feelings that come from participating	• "I don't know how to say it, but we get judged on the way we treat our babies because, especially like—and it's mostly other women like us that had kids before. So we are judged a lot and we are always doing stuff and people sometimes don't appreciate moms and we should be more appreciative." [Quote 8; participant 3] • "I feel like the closed groups have always been more polite, more well-mannered, you know, because there's always those people out there who are—have got to be rude and condescending and you know look down on people and they don't know the like everybody has their own situation, you know like there's just always one of those people there who has to be a negative Nancy." [Quote 9; participant 4] • "I feel moderation is more important than the actual content of the posts. So long as everything is moderated and it's not necessarily censored but it's done in the right mindset, then it's easier to get along with their group to appreciate what's going into it rather than it just being meme central and turning very quickly into something you don't want to engage in." [Quote 10; participant 13]

XSL•FO
RenderX

Themes and subthemes	Illustrative quotes
Engagement with a Facebook group	• "I know there's a lot of people who don't feel comfortable um disclosing information, like something that they would feel ashamed of, you know, being a first-time mom and I feel like if you do feel ashamed of something that you don't know what's going on and you need the advice, I feel like having an anonymous post is perfect because then you can get the advice or experiences that you need without having to feel like you're being a bad mom or you know, being a bad parent in that sense." [Quote 11; participant 6]
Social connectedness	
Expanding social network	• "Well, one thing about going to Facebook for stuff like that is you'll get opinions from different people, from people all over actually. So it's not just geared to one type of population or something like that, but it would give opinions and thoughts of a variety of different people." [Quote 12; participant 10]
Community building	• "Yeah, I was definitely a lot lonelier when I had a newborn. I wasn't working either. So that was my only adult time was these other moms on the internet who were probably in the exact same phase that I was, but right now I can get out of the house, my kids are older, they're in school, they're independent. So I have a little more flexibility and freedom, especially with working. I can go into the office and have adult time." [Quote 13; participant 14] • "Everyone's going through the same thing at the same time. You're always talking to people who are either new moms or pregnant, trying to learn or trying to better themselves for their kids, which is the kind of environment you want to foster." [Quote 14; participant 13]

Information Seeking

Three subthemes were developed from descriptions of using Facebook private groups for information seeking: (1) quality and trustworthiness of the information; (2) accessibility of the information; and (3) ability to find information about specific topics, such as product information, parenting tips, tricks or hacks, and parenting styles or approaches.

Quality and Trustworthiness of the Information

Many participants noted that the information they received on Facebook private groups felt more trustworthy because it came from real people with similar experiences and the shared goal of being better parents (quote 1 from participant 17 in Table 2). They generally found that the information was both practical and honest. Some referred to trusting advice on specific questions they asked and on products others had used. However, others were more skeptical of any advice from social media, including from Facebook private groups, because they thought that they were likely based on information from, for example, bots or people who could personally gain from the advice they give (quote 2 from participant 17 in Table 2).

Accessibility of the Information

Participants liked the accessibility of Facebook private groups and often noted that they provided a venue where they could have their questions answered quickly at any time of day (quote 3 from participant 12 in Table 2). They also liked the searchability of the groups so they could find advice without actively asking (quote 4 from participant 20 in Table 2).

Some found that Facebook private groups, though closed, were still easily accessible without a long wait and liked that the vetting process provided some assurance about who was in the group (quote 5 from participant 17 in Table 2). Several participants also mentioned that many people already know about Facebook, which could facilitate quick access (quote 6 from participant 37 in Table 2).

Specific Topics Sought

Facebook private groups were viewed by participants as an easy way to ask specific questions to receive targeted responses. Parenting hacks, product recommendations, breastfeeding advice, and parenting styles were frequently referenced by participants as sought-out information on Facebook private groups. Pregnant persons also wanted to know whether symptoms they were feeling were experienced by others (quote 7 from participant 17 in Table 2).

The Experience of Engaging With Facebook Private Groups

The experience of participating in Facebook private groups played an important role in participants' willingness to use Facebook for a group whose primary objective was to provide education to parents, even if they did not otherwise use the platform. The 2 subthemes that were developed were feelings experienced while participating and different ways of engaging with such groups.

Feelings That Come From Participating in Facebook Private Groups

Participants frequently referenced negative feelings, most notably judgment and embarrassment, which can come from social media in general (quote 8 from participant 3 in Table 2), and felt that Facebook private groups provided more privacy

XSL•FO
RenderX

and positive experiences with support rather than judgment, more honesty, and better social manners than nonprivate Facebook groups or other social media venues (quote 9 from participant 4 in Table 2). Thus, participants were interested in and sometimes actively sought Facebook private groups where they would feel more comfortable. They credited group moderation, screening of members, and the shared experience of members for this more favorable experience (quote 10 from participant 13 in Table 2).

Engagement With Facebook Private Groups

Participants liked that Facebook private groups offered the ability to engage in multiple ways. Some participants liked posting, whereas others preferred to only comment on others' posts or more passively read and "like" posts. Most felt that the ability to post anonymously created a safer space with more positive feelings (quote 11 from participant 6 in Table 2). Some participants also said that they preferred to engage with moderated groups so that the conversation remained civil.

Social Connectedness

Participants overwhelmingly felt that taking part in groups fostered social connectedness through the subthemes of community building and expanding social networks at a time that can be isolating.

Expanding Social Networks

Those participants who had used new parent groups or other affinity groups before reported that they were able to expand their social network and connect with other new parents. Participants also noted that, while parents in these groups share that they are all in a similar phase of life, because the groups are online, they are often more diverse than their personal social networks and, thus, could provide different ideas and perspectives from those of their families and close friends (quote 12 from participant 10 in Table 2).

Community Building

Shared experience was often cited in building a dynamic community in Facebook private groups. Participants described Facebook private group communities as providing support, understanding, and advice. Participants sought this type of community more at different times in their lives, with some describing needing it more with their first child, whereas others needed it more during later pregnancies due to the loss of a supportive parent or family member or moving away from previous supports (quote 13 from participant 14 in Table 2). Several participants noted the opportunity to build community around shared experiences (quote 15 from participant 13 in Table 2).

Discussion

Principal Findings

For this study, we set out to understand the perspectives of pregnant persons and new mothers regarding the use of Facebook private groups for learning about infant care practices, with a focus on those that reduce the risk of SUID, namely, safe sleep practices and breastfeeding. We discovered that, regardless of their feelings about using Facebook in general, participants expressed openness to and excitement about using Facebook private groups to learn about infant care practices. Many participants described Facebook private groups as providing trustworthy and easily accessible information and a more positive engagement experience compared to other social media and assisting in expanding their social networks. Furthermore, many felt that Facebook private groups created opportunities for social connectedness and support during a difficult transition period. Participants saw particular value in the shared experience and connectedness of the private group and its ongoing conversation. Despite reservations about Facebook in general, they expressed trust in the advice of other parents in Facebook private groups that are monitored over unmoderated material across social media.

Our findings on the acceptability of Facebook private groups for a parental health intervention are consistent with those of existing literature. Previous qualitative studies have primarily looked at the experience participants had in Facebook private groups or analyzed the transcripts of existing Facebook private groups. Groups have been viewed positively and described as a source of support and advice for parents with children with rare or challenging diagnoses, for childhood obesity prevention [6,16,17], for infant health information [18], for breastfeeding support [19], and for parents during the COVID-19 pandemic [20]. The themes that were generated through our study regarding why participants wanted to use Facebook private groups are also consistent with those found in previous literature on why new parents use Facebook private groups and the internet more broadly [7].

Our results also help further elucidate the reasons why we believe Facebook private groups facilitated by health care professionals have the potential to have a powerful impact on safe sleep and breastfeeding practices. Many of our participants acknowledged the postpartum period as a vulnerable time where they felt isolated and looked for easily accessible support and advice. Our participants described the support they received from closed groups as helping establish trust in the advice they received. While we hypothesized that they would come to Facebook private groups specifically for this peer support, the quality of moderation of the group was also valued by many participants who wanted to ensure that the advice was reputable. This is consistent with a study looking at Facebook private groups for parents with children with rare disorders, which found that 79% of participants would have liked a physician or medical professional to be in the group [21]. Thus, physician advice provided in a support group is likely to be both accepted and highly trusted.

Strengths of this study include sharing the perspectives of pregnant persons and mothers who are WIC clients, representing a group that is at high risk of SUID. We included participants from 2 cities. Similarly to all qualitative studies, our findings are not generalizable, and further research should explore the perceptions of caregivers in other demographic and geographic groups.

XSL•FO
RenderX

Conclusions

Although their experiences with and opinions on Facebook vary, pregnant persons and mothers of young infants use and generally feel positive about Facebook private groups. Thus, these groups can serve as a useful platform for an intervention to encourage safe sleep and breastfeeding by providing education, support, and social connectedness during the postpartum period.

Acknowledgments

The authors are grateful to interviewer Courtney Rogers for their contribution to this study.

Funding

This study was supported by the National Institute on Minority Health and Health Disparities (grant R01 HD110568).

Data Availability

Intellectual property and data generated under this project will be managed in accordance with both participating institutional and National Institutes of Health (NIH) policies, including the NIH Data Sharing Policy and Implementation Guidance of March 5, 2003, which was the policy guidance in effect when this project was funded. Materials generated under the project will be disseminated in accordance with participating institutional and NIH policies. Depending on such policies, materials may be transferred to others under the terms of a material transfer agreement. We have provided the scientific community with access to data collected during our prior studies, and this will continue with this study as well. This includes survey instruments and datasets. Researchers can contact our research staff for a request form that can be used to request access to the datasets and support for their use. Data will typically be made available to the public approximately 1 year after surveys are completed. Access to databases generated under the project will be available for educational, research, and nonprofit purposes. Such access will be provided using web-based applications as appropriate. Publication of data shall occur during the project, if appropriate, or at the end of the project, consistent with normal scientific practices. The final locked dataset will be stripped of all participant identifiers (including but not limited to name, date of birth, address, or phone number). This dataset will be available to the nonprofit community for noncommercial uses, provided that a data sharing agreement is reached and that the original creators of the dataset are able to collaborate in all secondary data analyses.

Abstract

Background: Greater caregiver knowledge of early language development may support more reciprocal interactions with infants and improved child language outcomes. Short-form video interventions on social media platforms like Instagram and TikTok could be a scalable, cost-effective way to increase caregiver knowledge.

Objective: The objective of this investigation is to describe the development and testing of a version of the BabyTok Project, a social media–based intervention for caregivers of very young infants under 3 months of age.

Methods: We used a multiple-method, pre-post quasi-experimental design to examine the feasibility, acceptability, and initial evidence of effectiveness of the BabyTok Project through a knowledge measure called the SPEAK-R (Survey of Parent/Provider Expectations and Knowledge–Research).

Results: Engagement metrics, participants' postintervention surveys, and feedback support the feasibility and acceptability of the intervention. Statistically significant scores on the SPEAK-R offer initial indications of change in caregiver knowledge.

Conclusions: The BabyTok Project has multiple demonstrations of its feasibility and acceptability and shows promise as a means to increase caregiver knowledge of early infant communication development and strategies to enhance children's learning. Interventions like the BabyTok Project could be a scalable way to promote optimal child language outcomes.

Introduction

Early Language Development

Infants are born interactional partners, and their earliest experiences with caregivers set their trajectory for language acquisition in the years that follow [1]. Infants who experience frequent, responsive, back-and-forth interactions go on to have a better understanding of language, larger spoken vocabularies, more complex grammar, and stronger reading, writing, social-emotional, and economic outcomes later in life [2-5]. The impact of these reciprocal exchanges is also visible in children's neuroanatomy [1,4,5]. Infants who experience more back-and-forth vocal turns with caregivers in the first year of life have denser white matter tracts in areas of the brain that are responsible for understanding and production of language, suggesting that the cumulative impact of early interactions begins in the first year of life [1]. For infants whose families experience economic hardship, responsive interactions serve as

XSL•FO
RenderX

a protective factor against the wide-ranging negative neurodevelopmental consequences of poverty on early learning [6,7].

Promoting positive, responsive early interactions is a well-established way to improve children's language learning in communities that are experiencing poverty [8,9]. However, most interventions that aim to support caregivers to engage with their children are limited in two ways. First, many interventions begin later in toddlerhood rather than the earliest months of life [8]. Although these programs are still meaningful during toddlerhood, infants' brains develop networks that specialize in language from the very first days of life [1]. As such, promoting optimal child language learning should begin at or even prior to birth. Second, most interventions that aim to enhance the frequency and quality of infant-caregiver interactions use a coaching model in which a professional observes, guides, and gives feedback to caregivers. These interventions have a long history of evidence [10-12]. However, scaling preventative coaching models population-wide is difficult due to the cost of implementation [8], instability in funding, and variability in what home visiting programs operate in each state.

Light-Touch Interventions

Because coaching models are costly, researchers suggest the need for scalable, population-level interventions that increase caregiver knowledge of early language learning [8]. Compared to other areas of health sciences like smoking cessation [13], HIV prevention [14], or breastfeeding promotion [15], there have been relatively few investigations of mobile health efforts to promote optimal child language development. Research in this area is critical as approximately 30% of infants and toddlers whose families have low incomes are late talkers who may need ongoing and more intensive language interventions when they reach school [16]. One way to increase child language outcomes is to increase what caregivers know about early language learning [17]. Caregiver knowledge of early development is linked to more frequent and more responsive language interactions, so building caregiver knowledge is an important avenue for universal interventions at the population level [17]. Below, we highlight 2 mobile health, light-touch interventions to enhance caregiver knowledge and strategy use to promote their child's early language learning.

Háblame Bebé is a free Spanish-English mobile app designed to promote early bilingual language development among infants and toddlers by supporting parents to provide rich, engaging verbal input [18]. Early evaluations of the app indicate promising outcomes for enhancing parents' knowledge and language-supportive behaviors [18-20]. In a quasi-experimental study, researchers found that mothers who used the app increased the amount and quality of their language directed toward their children during play and shared reading [18]. Postintervention, participant mothers produced more total words, asked more questions, and demonstrated a stronger sense of pride and confidence in using Spanish with their children [18]. A subsequent randomized controlled trial assessed the app's impacts on both caregiver behaviors and early child language outcomes when implemented in real-world conditions without researchers' support to access and use the app [20]. Although the trial did not find statistically significant group differences in standardized child language scores, effect sizes favored the intervention group. Caregivers also reported high usability, acceptability, and satisfaction levels with the app as a light-touch intervention, highlighting its accessibility and cultural relevance [21].

Caregivers of infants in the United States widely use the internet social media platforms for information seeking about their child's health and development [22-25]. Unlike Háblame Bebé, which uses a standalone app, we created an intervention called the BabyTok Project to connect caregivers (eg, parents and infant/toddler teachers) [26,27] with evidence-based information via short-form videos on TikTok. Through initial testing, both sets of caregivers endorsed the intervention as feasible and acceptable, and caregivers reported that they learned new information that helped shape interactions with infants and toddlers in their care. These studies also provide information about engagement metrics for this type of intervention. While the 2025 investigation indicated positive directional change in caregiver knowledge, the gains were not statistically significant, perhaps due to the underpowered nature of the feasibility study and the short-term nature of the intervention. In the present iteration of the BabyTok Project, we extend the intervention to caregivers whose infants are under 3 months old to maximize the impact of responsive interactions with a larger sample size, and we lengthened the intervention to approximately 4 months.

Purpose of the Study

The purpose of this study was to describe the development of a social media–based intervention specific to the needs of caregivers of young infants (under 3 months) and to conduct a pre-post pilot test of the BabyTok Project to explore whether there are gains in caregivers' knowledge of early language development. We also aim to explore caregivers' perceptions of the intervention content and delivery to directly inform a larger-scale randomized controlled trial.

Methods

Study Design

This study used multiple methods, qualitative methods through focus groups during the development phase and a pre-post quasi-experimental design during the pilot, to determine feasibility and acceptance of the BabyTok Project, a 22-week intervention using social media to promote child language development. Data were collected to help evaluate user activity and engagement within the app, short-term effects on caregivers, and overall usability. Data were also used to support future adaptations and improvements to the intervention.

Intervention: The BabyTok Project

Content Development

Prior to the intervention, we created sample videos to share with focus groups to gain caregiver input before proceeding with full video development of the intervention. The fourth and fifth authors helped to design focus group protocols to learn more about how caregivers use social media, what types of content

XSL•FO
RenderX

they search for related to their infants, and what makes a video catch and keep their attention. We also showed samples of the BabyTok Project videos to solicit feedback on style and content. Additionally, at the end of each focus group, we provided a list of video topic ideas and invited participants to share their opinions to help us understand more about what topics related to language and communication are most important to caregivers of infants. The focus group participants were recruited via an ad on Instagram, which ran for 4 weeks from mid-December 2023 to mid-January 2024. The ad used a URL code that sent potential participants to a Qualtrics form, which requested name and contact information. Those who gave their information were contacted via email and were asked the age of their infant and their caregiver status. Then, they were emailed a link to a Qualtrics survey, which included demographics and income-related questions. To be placed in a focus group, participants needed to be a caregiver of a child aged 0 to 6 months and qualify for social services such as Medicaid, housing assistance, TANF (Temporary Assistance to Needy Families), WIC (Women, Infants and Children), and/or food pantry/other goods. We conducted two focus groups with a total of 8 participants. The first focus group consisted of 3 participants who all reported being parents of infants, male, between the ages of 29 and 32 years, and Black or African American; 2 reported having a bachelor's degree and 1 an associate's degree; 2 reported living in an urban area and 1 reported living in a rural area. The reported income distribution among them was between US $40,000 and US $79,999. All 3 participants reported speaking English. The second focus group consisted of 5 participants who all reported being parents of infants, female, and between the ages of 24 and 32 years. Four participants reported being Black and 1 reported being Black and Hispanic/Latino; 1 reported having a bachelor's degree, 2 reported some college/associate degree, and 2 reported having a high school diploma; 3 reported living in a suburban area, 1 reported living in a rural area, and 1 reported living in a small town. The reported income distribution among them was wide, with reported earnings of US $20,000-29,999, US $30,000-39,999, US $70,000-79,999, and US $80,000+.

The groups were conducted via Zoom by the sixth author and were video- and audio-recorded. The third author and a trained undergraduate assistant attended the groups to help with any technical difficulties and to take notes. Participant responses were recorded via note-taking and read back to them at the end of each session to verify their answers. At the conclusion of the groups, one researcher synthesized the notes and asked for feedback from the other researchers on the team. The synthesized notes were also emailed to the participants for feedback to ensure that we described their opinions accurately. Opinions gathered from the focus groups regarding content they tend to watch and follow on social media indicated that the trustworthiness of content and content creators is of high importance. In addition, the focus groups discussed the importance of content being relatable and enjoyable to watch, with content that grabs your attention quickly described as preferable. The groups agreed that they scroll past content that does not have an immediate hook. When shown the sample videos, they overwhelmingly preferred videos with real caregivers and their babies. Participants also preferred videos with the speaker talking directly to the camera, videos with movement and some music but not too loud to be distracting, and videos with captions. The groups agreed that they enjoyed the educational content of the videos and that the information provided was valuable. Some critiques of the videos were that some were too fast and hard to follow, and the volume of background music was too loud. One focus group participant shared that some of the videos felt overproduced and more like an advertisement from a nongovernmental organization, and other focus group participants agreed. When asked for their opinions on topics they would like to see in future videos, participants were interested in information on children with delays and sign language for babies. This feedback from the focus groups was considered and integrated into the creation of the social media content for the intervention phase of the research. Participants were each emailed a US $50 virtual gift card at the conclusion of the focus groups.

Content Description

The project's fully developed content included 48 videos, each about 1 minute long, all posted on Instagram Reels. All videos were filmed and edited by a professional videographer, with the first author serving as the narrator. Each video featured the first author as well as B-roll clips of several families who volunteered to model for videos. The project also included 13 still posts with facts, affirmations, or questions as prompts to create a more natural, community feel, encouraging parents to engage, comment, and share as they would on a typical Instagram page. Three videos were also reposted as examples to illustrate concepts and activities discussed. Video content was created using the best available research on early language development and caregiver interactions [26,27]. The first video served as an introduction, guiding parents on what to expect during the study and introducing the first author's background as a speech-language pathologist, professor, researcher, and mother. The remaining videos covered the following topics: brain development, affirmations, early cues, routines, books, and specific strategies. For more detailed information on video content, see Table 1.

XSL•FO
RenderX

Table 1. BabyTok Project content descriptions (n=64).

Topic	Posts/videos, n (%)	Purpose
Brain development	5 (8)	These videos teach caregivers about early brain development and how infants' brains are primed for learning language from birth.
Affirmations	5 (8)	Affirmation videos were shared to provide encouragement, confidence, and emotional support to caregivers.
Early cues	6 (9)	Babies communicate as soon as they are born through cries, fusses, and their movements. These videos help parents to recognize and interpret their baby's cues, give tips on how to respond, and boost their future communication skills.
Routines	4 (6)	Everyday routines help establish a sense of predictability that supports babies' learning. These videos help caregivers build routines by providing guidance about how to build in predictability around caregiving tasks, book sharing, and more.
Books	6 (9)	These videos highlight the benefits of reading even to young infants, and we provide tips on effective strategies like following children's attention/gaze and selecting engaging books for infants.
Specific strategies	14 (22)	These videos share ways caregivers can support language development through everyday interactions. They cover strategies like infant-directed speech (parentese), modeling language, using baby signs, and playtime tips to encourage tracking and reaching.
Myth busting	8 (13)	This section of videos addresses common concerns, developmental milestones, and misconceptions during a baby's first year, covering key topics like bilingualism and screen time.
Still posts	13 (20)	Still posts were used to provide announcements to participants, informative facts, affirmations, and question prompts to encourage participant engagement.
Reposts	3 (5)	TikTok reposts served as examples of previously discussed concepts (eg, signs to use or songs to sing) as well as sharing helpful tips from other parents. Reposts were also used to capture a greater demographic range of caregivers featured in the videos.

Fraud Prevention

Given the virtual nature of this study, we implemented a fraud prevention strategy to ensure data integrity and prevent masqueraders (individuals or bots who submit fraudulent responses) from participating in the study. The survey was completed on Qualtrics and received 308 responses. The first line of defense to prevent fraudulent responses was adding the Qualtrics Re-captcha feature to the initial 2-question prescreener. This feature did not detect all potential fraud. Therefore, to ensure that our participants were real individuals and to prevent ineligible participants from entering the study, we used a fraudulent response detection process, which included filtering out Qualtrics's identified bots and incomplete surveys, removing respondents with duplicate IP addresses and locations outside of the United States, and removing respondents who gave unintelligible or inappropriate answers to open-ended questions [28]. To provide extra verification, emails were sent with the following questions: (1) Are you a regular caregiver of a child? (2) If so, please provide the age of your child in months. If responses were inconsistent with survey data, these individuals were deemed ineligible to participate in the study.

Recruitment

Recruitment for this study began in the summer of 2024 through flyers that were distributed both in person and via email to local pediatric and obstetrics/gynecology clinics across the state of Florida. The flyer was also shared on social media platforms, including Instagram, TikTok, and Facebook. It featured a link and QR code that directed individuals to a survey containing 2 prescreening questions to verify caregiver eligibility. To be eligible, participants needed to either be pregnant and due on or before August 15, 2024, or have a child up to 3 months old, and qualify for social services such as Medicaid, housing assistance, TANF, WIC, and/or food pantry/other goods. Participants who were determined eligible were routed to a consent form to provide consent to the institutional review board–approved study. The recruitment period lasted 2 months.

Procedures

Once participants provided consent, they were sent an email requesting verification of their email address, cell phone number, Instagram handle, and their child's date of birth. After this information was verified for consistency with the demographic information, participants were sent a follow-up email that included links to the pretest measures, along with instructions for completing them. At this point, they were also asked to follow the study's Instagram page. Pretest measures included the SPEAK-R (Survey of Parent/Provider Expectations and Knowledge–Research) and demographic forms, which participants completed online via the links provided.

Once the pretest measures were completed and it was confirmed that all participants were following the social media page, researchers began sharing videos and still posts approximately 3 times per week. Participants were asked to watch and like posts to track content engagement. While commenting was encouraged, it was not prompted. Participants received reminders every other week via direct message through the Instagram app, email, or text messages from the research team to watch videos and like them. Following the intervention, participants completed the posttest measures, which included the SPEAK-R and a postintervention survey, all of which were completed online.

XSL•FO
RenderX

Ethical Considerations

All participants provided implied consent for the institutional review board–approved study (Florida State University Study #00005223) through an online interest form with a waiver of documentation of consent. Participants received up to US $200 in gift cards as compensation. Compensation was distributed via email after pretest data collection (US $100) and the social media intervention and posttest data collection (US $100). All participants were assigned an alphanumeric code for all data files. One single Microsoft Excel file linked personal information to the code. The linking file and deidentified files are kept in an encrypted Microsoft Teams folder hosted by the university.

Measures

SPEAK-R

Similar to the prior BabyTok Project studies with infant/toddler teachers and caregivers of toddlers [26,27], the SPEAK-R was used as a tool to quantify changes in parents' perceptions of their understanding of early childhood language development. The SPEAK-R is a 22-item, self-administered questionnaire designed to assess knowledge of and beliefs about early childhood cognitive and language development [29]. The questionnaire consists of 4 multiple-choice items, 14 Likert scale items scored as *definitely true* (0) to *definitely not true* (4), and 4 Likert scale items reverse-scored as *definitely not true* (0) to *definitely true* (4). The questions focus on six topics: (1) bilingualism, (2) early exposure, (3) media use for child learning, (4) nature vs nurture, (5) sensitivity and responsiveness, and (6) talking and reading. The SPEAK survey was developed and tested on multiple population samples that included caregivers with low incomes [29]. During development, the SPEAK showed significant, positive correlations between scores and level of education, receptive language skills, and quality of language in the home environment [29]. During field testing, the SPEAK-R was proven reliable with a Cronbach α score of 0.92 [29]. The tool also has a 0.24 correlation (P<.001) with the 10-item version of the Knowledge of Infant Development Inventory (KIDI) as evidence of its concurrent validity [30]. We administered the SPEAK-R via an online survey at entry and after the 22-week intervention. The measure was gathered and scored using REDCap, and the data were imported into SPSS for analysis.

Instagram Engagement Metrics

For the purposes of this study, we define engagement as "specific interaction and usage patterns" [31] with the app. Prior to the study, we opted to use a private account to help maintain a level of confidentiality for participants. Private Instagram account owners do not have access to data metrics, called Instagram Insights, which track views, impressions, saves, shares, and watch-through rate [32]. To obtain data regarding the participants' use of the BabyTok Project intervention, participants were asked to "like" posts to indicate viewing. As such, these metrics do not reflect an "organic" pattern of liking, but rather, as an indication that they interacted with the content. Participants were not specifically asked to comment; however, we gathered data on comments per post and per participant as a measure of engagement with the intervention. Data were collected by reviewing each post and documenting the number of likes and comments per post and per participant. After the study was completed, we analyzed the total sum of likes and comments per post and the total sum of likes and comments per participant across the 22 weeks of the intervention and calculated the mean, SD, and range for each. Additionally, feedback regarding the intervention was analyzed by reviewing and coding individual comments for each post.

Caregiver Postsurvey

To analyze the acceptability and feasibility of the intervention, we administered an online survey using the Qualtrics platform after the completion of the intervention phase. The postsurvey consisted of 13 Likert scale questions with 5 possible answer choices ranging from *strongly agree* to *strongly disagree*, 1 multiple-choice question about the most helpful content, and 3 short-answer questions regarding takeaways from the content, feedback regarding the content or delivery, and input on future content. Answers to the Likert scale and multiple-choice questions were gathered and analyzed for patterns. Short-answer questions were gathered and analyzed for patterns and themes.

Quantitative Data Analysis

SPEAK-R

We used descriptive statistics (mean and SD) and a paired-samples t test in R to describe changes in caregivers' knowledge and beliefs about early childhood cognitive and language development as measured by the SPEAK-R. Cohen d was calculated for the paired-samples comparison by dividing the mean difference score by the standard deviation of the difference scores [33].

Instagram

Instagram data were collected using a simple count of likes and comments per video and per participant. We used a descriptive quantitative analysis to show the means and ranges of Instagram engagement metrics.

Qualitative Data Analysis

Instagram

Instagram comments were analyzed using the thematic analysis method prescribed by Brooks et al [34]. The second and third authors explored the data separately, and through an iterative process of meetings, constant comparisons, and continued data exploration, common and interesting themes emerged. Through consensus, the themes were labeled as codes, and at the conclusion of this analysis, a simple count of each code was collected to understand more about the engagement of the participants. Throughout this analysis process, the primary author was consulted to ensure the quality of data coding.

As with the previous BabyTok study [27], the data analysis team took several steps to ensure the trustworthiness of the data. To increase the trustworthiness of our findings, our approach included immersion with the data, independent coding with discrepancies resolved through consensus, debriefing with the primary author, and cross-checking for coding reliability [34]. To increase transferability, we provided definitions and several

XSL•FO
RenderX

examples of participant comments. To ensure dependability of the data, we kept detailed records and an audit trail.

Caregiver Postsurvey

The responses to the short-answer questions in the postsurvey were also analyzed using the template analysis method described in Brooks et al [34]. The second and third authors followed the same process for analyzing the data that was followed for analyzing the Instagram comments. Throughout this process, the first author was consulted to ensure the quality of data coding. To ensure the trustworthiness of the data, we followed the same procedures outlined by Nowell et al [35] as described above in the qualitative analysis of the Instagram comments.

Results

Participants

After the verification and fraud prevention processes were completed, a total of 31 participants across the United States were included in the study. Among the participants, there were 27 mothers and 4 fathers. There were 15 participants in the 20-29 years age range, 15 in the 30-39 years age range, and 1 that was 40-49 years old. Of the total participants, 10 were White, 16 were Black, 2 were Hispanic/Latino, 2 were Hispanic/Latino-White, and 1 was Black, White, and Hispanic/Latino. All 31 participants spoke English, 4 spoke both English and Spanish, and 1 spoke both English and Yoruba. For more demographic information, see Table 2.

Difference	6.68 (8.18)

[a]t_{30}=4.54; *P*<.001; 95% CI 3.68-9.68; Cohen *d*=0.82.

Instagram Engagement

To ascertain which posts (videos and/or still posts) generated the most engagement, we examined the number of likes per post and the number of comments per post. Engagement rates were slightly higher for video content compared to still posts. On average, videos received 27 likes and 6 comments per post, compared to 24 likes and 5 comments per post for still posts. A video about postpartum depression and anxiety received the most likes, with all 31 participants liking the video. Three posts garnered 30 likes; they were a video about understanding infant cues, a video with ideas for communication activities during wake windows, and a video about how to respond when the cries of your baby are too much. Eleven posts received 29 likes, including but not limited to a video about what a baby's brain needs in the first few weeks, a video about strategies to calm a baby, a video about the myth of spoiling a baby through too much holding, a video about how to talk to a young infant, and a video about how to play with a young infant. Notably, videos that were posted toward the end of the 18-week intervention period received fewer (23) likes. These videos included 2 videos about babies and screen time and 2 videos about communicating with babies in a bilingual family. The post that received the least number of likes (20) was posted last and was a video titled "Things That Might Cause Concern in the First Year." On average, viewership of each post averaged 85% (26.48 likes out of a possible 31 likes); mean=26.48 likes per video, range=20-31, mode=27. The number of comments per post ranged from 0 to 20 (mean 5.69, mode 3, 4). The post with the greatest number of comments (20) was the video titled *You Can't Spoil a Baby*. A video about postpartum depression and anxiety had 16 comments, along with a video about understanding your baby's cues. The post with the fewest (0) comments was a video about communication skills to expect during the first year. Videos with 1 comment each included a video about research on routines for babies, a video about baby signs, a still post with a baby sign guide, and a video about how to read to a baby.

We also analyzed the number of likes per participant and the number of comments per participant. Participants were asked to like a post as confirmation that they engaged with the content; 13% (4 out of 31) of participants watched all video posts, and 84% (26 out of 31) of participants watched more than half of the videos (mean likes per participant=49.55, range=21-58, mode=57). The number of comments per participant was also gathered to understand more about participant engagement; mean=10.65, range=0-48, and mode=2. One participant engaged with 48 comments, 5 participants commented more than 20 times, and 5 participants did not comment at all throughout the course of the intervention.

Caregiver Postsurvey

Following the intervention phase, the postsurvey was administered to gather caregiver perspectives of the intervention (see Multimedia Appendix 1). Results showed that the statements most frequently agreed upon were "The information shared was interesting" (27/31 [87%] strongly agreed), "The information and language used were clear and easy to understand" (27/31 [87%] strongly agreed), and "The videos helped me feel confident that I can help my child's language learning" (27/31 [87%] strongly agreed). The statements with the lowest level of agreement were "Watching the videos changed my routines with my child" (16/31 [52%] strongly agreed; 9/31 [29%] agreed) and "I shared the videos with friends and family" (16/31 [52%] strongly agreed).

When asked, "What specific topics of videos did you find the most helpful or interesting?," the majority of caregivers (26/31, 84%) selected *baby gestures*, followed by *early cues* and *brain development* (23/31, 74%). The topic with the lowest number of votes was *shared attention* (13/31, 42%).

Qualitative Results

Participant Instagram Comments

Thematic Analysis

Through the qualitative data analysis process described in the Data Analysis section, initially 8 themes emerged: *venting*, *sharing*, *supporting each other*, *learning*, *practicing strategies*, *positive feedback*, *changes made*, and *questions*. At this stage, each of these themes was assigned a color, and each researcher separately coded the comments by highlighting them with the assigned color. After this initial coding process, the team met again to review each other's coding for discrepancies and to define the codes with more specificity. The team agreed that some changes to the codes were necessary to more clearly describe the data. Specifically, *venting* was renamed as *sharing a challenge*. *Sharing* was changed to *sharing positive experiences* and was defined more clearly as sharing about their babies' growth, milestones, and/or positive personal experiences but did not include discussing a challenge. *Learning*, *practicing strategies*, and *changes made* were merged under one code titled *learning through BabyTok*. The code titled *nonaligned/unclear intent* was added to label comments that did not match the topic of the video or post. Additionally, the code of *general comment* was added to describe a brief comment that expanded on the content topic. The resulting 8 themes are labeled and described in Table 4.

XSL•FO
RenderX

Table 4. Themes from analysis of participant Instagram comments.

Theme	Definition	Example comment
Sharing positive experiences	Participants shared updates on their babies' growth, milestones, and/or positive personal experiences.	"I love talking to my baby and reading him my favorite books! He's only three months and is babbling SO much."
Sharing a challenge	Participants' comments were related to struggles and/or venting about challenges related to the baby or about being a caregiver.	"The first couple of weeks after postpartum I was alone and had to deal with the baby and myself. On one particular night she was crying non stop. I tried everything I could to try and comfort her but nothing helped and I cried with her...it felt like such a sad moment to me because I felt hopeless and without sleep."
Learning through BabyTok	Participants commented about learning something new, using a specific strategy, and/or making a specific change because of information learned from the videos.	"Through this page I've started to narrate what I do with my baby. If I'm making her a bottle, if I'm changing her, just making small talk, etc. and she understands and starts to coo which is very very cute! I like that she's able to distinguish my voice from others and starts to move around."
Supporting each other	Participants made comments that were supportive of other participants.	"I totally understand some days I feel like this as well. Keep pushing mama you got this."
Positive feedback	Participants made comments that were compliments, positive statements, and/or emoji related to the videos, posts, topics, and/or BabyTok in general.	"I love this ❤."
General comment	Participants made comments that were statements related to the content that expanded on the topic.	"Reading helps with cognitive growth, especially pictures."
Nonaligned/unclear intent	Participants' comments were unrelated, nonsensical, had unclear intent, and/or did not align with the content of the video or post.	"I can really relate to this." (This comment was in response to a TikTok video repost with Ms Rachel modeling baby signs.)
Questions	Participant comments were questions for the BabyTok facilitator.	"During my babies wake window I try doing tummy time but she flat out refuses to exercise or stay with her arms crossed for more than 5 minutes. Any tips or suggestions?"

Instagram comments findings based on Table 4 themes are described in more detail below. Additionally, key participant comments are included to help contextualize these results.

Sharing Positive Experiences

Throughout the intervention, participants shared positive experiences with each other, such as sharing about their babies' growth, milestones, and/or positive personal experiences related to caregiving of their baby. One participant shared the following about her baby when commenting on a video about understanding your baby's cues:

> *I've been experiencing this lately! My daughter just turned two months & she's really good at letting me know with her facial expressions when she's hungry or wants to be held so she can nap.*

Another participant commented the following on a video about free things to do in the community with the baby:

> *When we run errands I usually like to point stuff out & tell her what it is. Like if we're at the grocery store I'll say, this is an apple or we need beef. Just to have a little conversation with her & show the item.*

Sharing a Challenge

Participants shared comments related to the challenges faced as a caregiver of an infant. When responding to one video post about postpartum depression and anxiety, there were several participants who shared their struggles. One participant commented, "Most times i feel like I'm loosing myself ...postpartum stress is not really easy." On a video posted about wake window routines a participant commented, "Right now im so tired i talk to her and watch her sisters play. I'm exhausted lol not much energy I have..."

Learning

Participants made comments related to learning from the BabyTok Instagram page. One participant commented about changes she has made because of the BabyTok intervention:

> *Through this page I've started to narrate what I do with my baby. If I'm making her a bottle, if I'm changing her, just making small talk, etc. and she understands and starts to coo which is very very cute!*

Another participant commented that she plans to try a playtime strategy that was introduced in a video titled *Using Toys for Tracking*. Her comment was, "I'm going to start incorporating this during my babies wake time. thank you!"

Supporting Each Other

Participants also showed support for each other with comments like, "I totally understand some days I feel like this as well. Keep pushing mama you got this," and "Happy new week fellow moms!" Participants sometimes shared strategies directly with another participant to be helpful. One participant was worried about her baby getting a flat head due to always sleeping on one side, and another participant commented the following:

XSL•FO
RenderX

> *Does she sleep facing a certain way? If so, you can try putting her head where her feet usually are. Then if she sleeps facing out the same way, she is now on her other side. (If that makes sense.) My niece also needed chiro and PT due to tight neck muscles on one side that led to her always wanting to face only one way.*

Positive Feedback

Participants provided positive feedback on the content and/or the BabyTok Project Instagram page in general with compliments, supportive statements, and/or emojis. One such comment was made on a video about reading with a baby at different times throughout the day. The participant wrote, "This project has really helped me and my newborn." Examples of other positive feedback comments that were made throughout the project were, "Thank you for sharing," "Interesting stuff," and "I love this ❤."

General Comment

Participants also made general comments that expanded on the content. For example, when commenting on a video about the benefits of reading books, a participant wrote, "Reading helps them with cognitive growth, especially pictures," and when commenting on a video about using wait time as a strategy, another participant stated, "Language is so important! Babies need that and also room to respond!"

Nonaligned or Unclear Intent

There were comments that were not aligned with the content or had unclear intent. One such comment was made on a video about free community routines. The participant's comment was, "I can relate." Another comment that was not aligned with the content was made on a video about the stress and anxiety that caregivers feel when babies cry for extended periods of time. The comment was, "Little miracles, there are such a joy."

Questions for BabyTok

Participants also asked questions in the comments for the BabyTok Project's facilitator, who was the first author. One such question was related to things to do with a baby during baby's wake window. The participant asked:

> *During my babies wake window I try doing tummy time but she flat out refuses to exercise or stay with her arms crossed for more than 5minutes. Any tips or suggestions?*

Another participant asked a question about a video that was posted about choosing books with real human faces to read to babies. The participant asked, "Could my baby enjoy this at two months?"

Caregiver Postsurvey

Thematic Analysis

Three open-ended questions were included in the caregiver postsurvey. They were "Please share any feedback or advice you have for us about the videos," "What was your main takeaway from the content posted," and "Please share what additional topics you might like information about in future videos." The main themes of *feedback and/or advice*, *main takeaways*, and *future videos* were derived from the questions in the survey. Through the template analysis process [10], the second and third authors individually studied the participant answers. The codes that emerged were *positive feedback*, *negative feedback*, *advice*, *empower*, *communication*, *strategy*, *informative*, *affirmation*, *change*, *postpartum*, *feeding*, *different ages/milestones*, and *delivery of content*. The two authors continued to analyze the data and met several times until consensus was reached. During this process, each author took notes about the coding process, thinking about the following questions: Did the codes fit well? Did new themes emerge? Did some codes overlap? Did the codes describe the data accurately? The main code of *future videos* was integrated into the *feedback/suggestions* code because there was crossover between the themes that emerged for each of these codes. Two main codes remained, and the subcodes for each main code were formalized and organized to more accurately describe the data. The code *main takeaway* was given the subcodes of *new information*, *empowering/affirming*, *strategy used/change made*, and *null/negative effects*. The main code, *feedback/suggestions*, was given the subcodes of *general positive statement*, *delivery of content*, *different ages/milestones*, *pregnancy and/or postpartum*, and *unrelated topics*. The themes along with their subthemes are described in Table 5.

XSL•FO
RenderX

Table 5. Themes from analysis of postsurvey open-ended responses.

Theme	Definition	Example participant response
Main takeaway		
New information	Caregivers reported learning new information from viewing the BabyTok Project videos.	"Learning two languages at the same time helps the brain to develop better, contrary to popular opinion that it may hinder language development."
Empowering/affirming	Caregivers recognized their own impact on their baby and/or felt their parenting communications were making a difference.	"There is no such thing as a perfect parent. Also that you can take charge and help with the development of your baby."
Strategy used/change made	Caregivers mentioned using a specific strategy and/or making a specific change because of information learned from the videos.	"I stopped letting my baby have screen time."
Null effects	Caregiver responding with no comment or nothing learned from intervention.	"Nothing really."
Feedback/suggestions		
General statement	Any general positive comment related to the intervention as a whole.	"I love this segment and truly hope it continues. As a new mom it's just so helpful."
Delivery of content	Any comment with advice related to how the intervention was delivered and/or the platform used for the intervention.	"...it would be nice if specific days were set aside for posting and not just randomly any day."
Different ages/milestones	Caregiver suggestions that future videos include additional ages of development from during pregnancy to older childhood.	"I'd love to have the option for different chapters such as pregnancy through toddlerhood, elementary through middle school, etc."
Unrelated topics	Caregivers mentioned other topics not related to early language development and communicating with the baby such as feeding the baby, teething, helping baby learn to walk, siblings, activities with baby, etc.	"I'd love topics such as starting solids, teething, and even fun activities to do."
Null effects	Caregiver wrote N/A, no additional comment, not sure, or left the answer box blank.	"No additional comment."

Thematic analysis of the open-ended questions yielded key findings, which are described in detail below.

Main Takeaway

When answering the main takeaway question, participants gave answers showing that they learned new information. One participant answered by stating, "How my everyday interactions with my child is helping her learn and grow even if they feel small." Another participant stated, "It is really important to play and talk with my baby." Participants also described feeling empowered or affirmed. One participant wrote, "There is no such thing as a perfect parent. Also, that you can take charge and help with the development of your baby." Additionally, participants described strategies learned from the intervention or a change made as a result of the intervention. For example, one participant wrote, "I've stopped letting my baby have screen time." Another participant wrote, "I loved how you talked about building routines not schedules. The pressure that I lifted off of myself was huge. Routines are much easier to navigate with littles than schedules." There was one null response from a participant who answered the main takeaway question with the response, "nothing really."

Feedback/Suggestions

Participants were asked to share their feedback, advice, and ideas about future topics for the Babytok Project. Participants answered with general positive statements such as, "I love this segment and truly hope it continues. As a new mom it is just so helpful," and "The project was really helpful for my infant and I." Participants also answered with suggestions about content and delivery. One participant wrote, "Have them at a set time," and another wrote, "...it would be nice if the specific days were set aside for posting and not just randomly any day." Another participant answered with, "should do more videos." One participant wrote that they would like to see more representation in videos stating, "Include more videos featuring Dads, Grandparents, and other caregivers to promote diversity and representation in parenting roles." Participants also wrote that they would like videos in the future to include additional developmental ages and discuss developmental milestones. One participant wrote, "...going through all the stages of childhood would be a great direction for the page...creating a series or episodes for different stages would be great." Likewise, another participant wrote, "I'd like it to continue to cover toddler age or at least the first year..." Participants also wrote that they were interested in receiving more information during pregnancy, with one participant writing, "I'd love to have access to something like this during pregnancy so I can also be prepared before baby is born..." Participants were also interested in more information on postpartum health, teething, baby foods, common health issues in infants, and information on motor skills. There were several (14) null answers with participants giving answers such

XSL•FO
RenderX

as N/A, no additional comment, or leaving the response box blank.

Discussion

BabyTok Project Iterations

This investigation builds evidence for the BabyTok Project social media intervention to support caregiver knowledge of early communication development. Caregivers of infants reported high levels of satisfaction with the intervention, and data from the quantitative measure indicate significant pre-to-post growth in caregiver knowledge of early child development, although these findings should be viewed in the context of the quasi-experimental design that does not have a control group. Given the correlation between caregiver knowledge of child development/language supporting strategies and the quality of very early interactions [17,32], this is a positive indication that light-touch interventions like the BabyTok Project may increase caregiver knowledge. Caregiver knowledge is known to mediate caregiver-child interactions, although a randomized controlled trial is needed to explore potential impacts of the BabyTok Project on real-time exchanges between infants and caregivers.

This iteration of the BabyTok Project began before 3 months of age and was longer than the toddler version of the BabyTok Project investigation with parents of toddlers (22 weeks compared to 8 weeks). These factors might explain the more sizeable increases in SPEAK-R scores in addition to the added statistical power achieved through a larger sample size. Although we did see decreases in engagement toward the end of the 22-week period, slightly longer interventions might be needed to ensure that caregivers are receiving enough of the content to increase their knowledge about early development.

Compared to other app-based interventions in which caregivers interact with in-app features and researchers, the BabyTok Project included a social element between caregivers in small groups. As we plan to expand and scale the project, we will retain the group nature of the intervention to encourage interactions between caregivers in the comments section on the videos. Because we monitor the comments, we are able to correct any false or misleading information that may appear. The benefit of this approach is that it enables caregivers to encourage one another, share ideas, and ask questions. Although it is not possible to disentangle the contribution of the "social" element apart from the content of the videos themselves, we believe it may be an important component that keeps parents engaged and that may build caregiver confidence by sharing information with one another. This approach does, however, complicate the available engagement metrics because watch time data are not available from private pages. Researchers who use social media platforms will need to balance the nuance of information available with privacy and confidentiality requirements of research.

Social media–based video content reaches caregivers on platforms like Instagram, on which they already spend time and search for information. Because social media–based interventions in this area are rare, we do not have many other contexts for comparison as it relates to the video watch rates and amount of engagement. Compared to our own prior work, however, this study had the highest percentage of videos watched, perhaps due to stronger implementation infrastructure with a research team member helping to distribute and follow up with participants every 2 weeks. This could be an important feature to ensure that the videos reach the intended audience, rather than relying on the algorithm alone to alert the users to new content. In fact, participants in past versions have noted that the algorithm did not return them to the page's content, so the direct messaging was essential. Contact with the research team also provided a checkpoint to make sure that participants were doing well, and in the future, it could also be an avenue to weave in a place for caregivers to ask questions about their child's learning/development if concerns arise, or even to promote the use of very early developmental screeners.

Implications for Other Caregiver-Focused Social Media Interventions

Participants in this study had several suggestions that are relevant to other social media–based studies outside of early language development. First, they recommended a predictable video release schedule so that they know when the videos are going to be posted (ie, Mondays, Wednesdays, and Fridays at 12 pm), although they did not specify preferred days and times for video distribution. Across studies, participants appreciated the direct messaging of content rather than relying on them to seek out the page or for the algorithm to deliver it. Participant feedback to include videos of multiple types of caregivers (ie, grandparents, aunts/uncles, and siblings) in the videos is also an important implication for other social media–based interventions for caregivers.

Limitations and Future Directions

Although the findings from this pilot study are promising, there are several limitations to note. Our pilot sample was small, and we did not verify the identity of the participants with a synchronous virtual meeting. We followed the bot and masquerader procedures described above, but verifying identities in a virtual meeting over Zoom would have been ideal and will be used in future investigations. First, it would enable us to ensure that the participants are caregivers of infants and not masqueraders on the internet. Second, it would enable us to meet and connect with participants in a more personal way that will be essential in a longer-duration randomized controlled trial that includes follow-up data collection and other measurements (ie, LENA [Language Environment Analysis] samples, observations, etc).

It is also important to note that our pool of participants had higher levels of education than one might expect from a low-income sample. This could indicate that caregivers with higher levels of education might have self-selected into the study. In addition, the pre-post quasi-experimental design precludes causal conclusions about the ability of the intervention to create change in caregiver knowledge. It is possible that caregivers gained information from other sources during the time they were in the study or that there was a testing effect from taking the SPEAK-R twice. It is also important to view the usage/engagement metrics within the context of the approach

XSL•FO
RenderX

used in this study. The videos watched do not reflect the "organic" rate that we may have achieved with little researcher support and outreach. While we do not view this as a limitation, per se, we do view it as an important implementation feature that is key for social media interventions that use short-form videos. In addition, the measure used in this study, while not developed by the research team, does not appear to have external validation studies. Still, it is one of the only tools that assesses caregiver knowledge of early communication.

Conclusions

Multiple studies with different sets of caregivers endorse the BabyTok Project as a means to learn about children's early communication. Given the established feasibility and acceptability of the approach and preliminary evidence of changes in knowledge, future studies will examine whether the approach can enhance caregiver-child interactions during infancy and, as a result, if children whose parents received the intervention have stronger language outcomes than a control group. If future efficacy testing demonstrates positive changes in caregiver-child outcomes, the BabyTok Project and interventions like it could fill a persistent need for preventative, universal interventions to promote children's early language skills.

Abstract

Background: Patients with mucopolysaccharidosis (MPS) appear to have an increased risk of developing dental disease.

Objective: This study aimed to evaluate the status of dental caries and dental anomalies among Chinese patients with different types of MPS.

Methods: This retrospective study analyzed a consecutive cohort of 102 pediatric patients with MPS who visited the Department of Stomatology at the Capital Center for Children's Health between August 2010 and August 2025. Eligible patients were defined as those with a confirmed diagnosis of MPS who were aged ≤14 years at the time of their dental visit and had complete dental examination records available. Dental caries and anomalies were assessed through clinical records and radiographic data.

Results: Dental caries were observed in 55.9% (57/102) of patients, and no statistically significant difference was observed across the MPS subtypes (*P*=.72). Deep dentinal caries (d4-6mft) were observed in 40.2% (41/102) of the participants and contributed most to the total decayed, missing, and filled teeth index score. The overall prevalence of dental anomalies was 32.4% (33/102), with a statistically significant difference among MPS subtypes (*P*=.005). Patients with MPS type IV had a significantly higher risk of dental anomalies compared to those with MPS type II (odds ratio 6.32, 95% CI 1.55 - 28.28; *P*=.01), after adjusting for age and gender.

Conclusions: The prevalence of dental anomalies differed significantly across MPS subtypes, while that of dental caries did not. These findings emphasize the need for early, targeted preventive care and tailored dental interventions to improve oral health outcomes in this population.

KEYWORDS

mucopolysaccharidosis; dental caries; dental anomalies; pediatrics; retrospective

Introduction

Mucopolysaccharidosis (MPS) is a group of inherited conditions involving metabolic dysfunction. Lysosomal enzyme deficiency leads to the accumulation of glycosaminoglycans (GAGs), resulting in systemic symptoms, and is categorized into 7 primary types (I [Hurler], II [Hunter], III [Sanfilippo], IV [Morquio], VI [Maroteaux-Lamy], VII [Sly], IX [Natowicz]) caused by the deficiency of 1 of 11 different enzymes. The inability to break down GAGs leads to their abnormal accumulation within various tissues and cells, progressively resulting in cellular dysfunction [1,2]. Globally, the estimated prevalence ranges from 1.04 to 4.8 per 100,000 live births [3-5]. In China, a study conducted across 21 provinces and municipalities between 2006 and 2012 reported that among 376 diagnosed cases of lysosomal storage diseases, MPS accounted for 50.5% (n=190 cases), with MPS type II (MPS-II) being the most common subtype, comprising 47.4% of all MPS cases [6].

Dental and craniofacial abnormalities were frequently reported in patients with MPS [7,8]. Common oral manifestations included macroglossia, anterior open bite, delayed eruption of teeth, cystic lesions, and temporomandibular joint abnormalities [9,10]. These patients also exhibited a higher susceptibility to dental caries, underscoring the need for preventive oral health measures. Meanwhile, due to the low prevalence of MPS and the fact that oral health issues are not among the life-threatening manifestations of the disease, patients rarely seek dental care voluntarily, which explains the current paucity of research on dental caries in this specific population. While previous studies on dental health in patients with MPS have primarily consisted of case reports, small case series, and small cohort studies, the

XSL•FO
RenderX

overall oral health profile of these patients is poorly characterized.

Furthermore, MPS encompasses 7 distinct clinical subtypes, each exhibiting significant heterogeneity in systemic manifestations due to specific enzymatic deficiencies and the resultant accumulation of various GAGs (eg, dermatan sulfate, heparan sulfate, keratan sulfate, chondroitin sulfate, or hyaluronan) [11-14]. This systemic variability is likely reflected in oral health. For instance, the severe skeletal dysplasia, particularly prominent in MPS-IV, can lead to distinct craniofacial patterns, malocclusions, and potential impacts on tooth eruption and morphology [15]. Additionally, a Brazilian study involving 17 patients with either MPS-IV or VI found that enamel hypoplasia was observed exclusively in those with MPS-IV, while anterior open bite was present only in patients with MPS-VI [16]. Similarly, variations in the degree of soft tissue hyperplasia and the patient's capacity to maintain oral hygiene across different subtypes may influence caries risk. A UK single-center study reported a higher incidence of dental caries in patients with MPS-IV compared to the general population and other MPS groups [17]. Despite these plausible variations and growing international data, comprehensive and comparative analyses of oral phenotypes among MPS subtypes, particularly within the Chinese population, remain limited.

Therefore, based on electronic medical record data, this study investigated the prevalence of dental caries and dental anomalies among patients with different MPS subtypes and analyzed the correlation between dental anomalies and caries in patients with MPS to provide insights for improving preventive care and treatment strategies.

Methods

Ethical Considerations

This study was conducted in accordance with the Strengthening the Reporting of Observational Studies in Epidemiology (STROBE) statement. The study was approved by the ethics review board of Capital Institute of Pediatrics (SHERLLM2024031) and was registered with the Chinese Clinical Trial Registry (ChiCTR2400090276). All study procedures were in strict compliance with the principles of the Declaration of Helsinki, and written informed consent was waived due to the retrospective nature of the study. To protect patient privacy, all data were anonymized and deidentified prior to analysis. Access to the original medical records was restricted to the research team, and no personally identifiable information (eg, names, medical record numbers, or exact dates) was extracted or reported.

Patients and Study Design

This retrospective cross-sectional study included pediatric patients diagnosed with MPS who visited the Department of Stomatology at the Capital Center for Children's Health between August 2010 and August 2025. This study used a convenience sampling method based on consecutive cases. The inclusion criteria were as follows: (1) a confirmed diagnosis of any subtype of MPS based on enzymatic or genetic testing, (2) age ≤14 years, and (3) availability of a complete dental examination record. Patients were excluded if they had concurrent major systemic conditions (unrelated to MPS) that could severely confound oral health status, such as uncontrolled diabetes, severe congenital heart disease, autoimmune diseases with oral manifestations, or a history of radiotherapy to the head and neck region. On the basis of these criteria, a total of 102 eligible patients were included in the final analysis.

The retrospective collection of electronic medical records was initiated after the study was registered on September 29, 2024. For patients who had multiple visits, only data from their first visit were included in the analysis. It should be noted that the hematology department of our single-center hospital is the largest MPS center in the country, and most patients visiting the stomatology department were referred for routine pretransplantation check-ups prior to stem cell transplantation, rather than presenting with specific oral problems. Therefore, although the data were derived from the stomatology department, the primary purpose of the patients' visits was stem cell transplantation, not specifically for oral issues. This indicates that the results of the oral examinations do not solely reflect the oral health of patients who actively seek treatment for oral problems in the stomatology department, thereby reducing the likelihood of selection bias to some extent. The findings of this study are more representative of the oral health status of patients with MPS, rather than being confined to those with severe oral problems.

Data Collection

The dental conditions of these patients were assessed by reviewing historical clinical records and radiographic data. Data were systematically extracted from oral health records, including demographic information (eg, age and gender), MPS subtype classifications, and comprehensive dental evaluations.

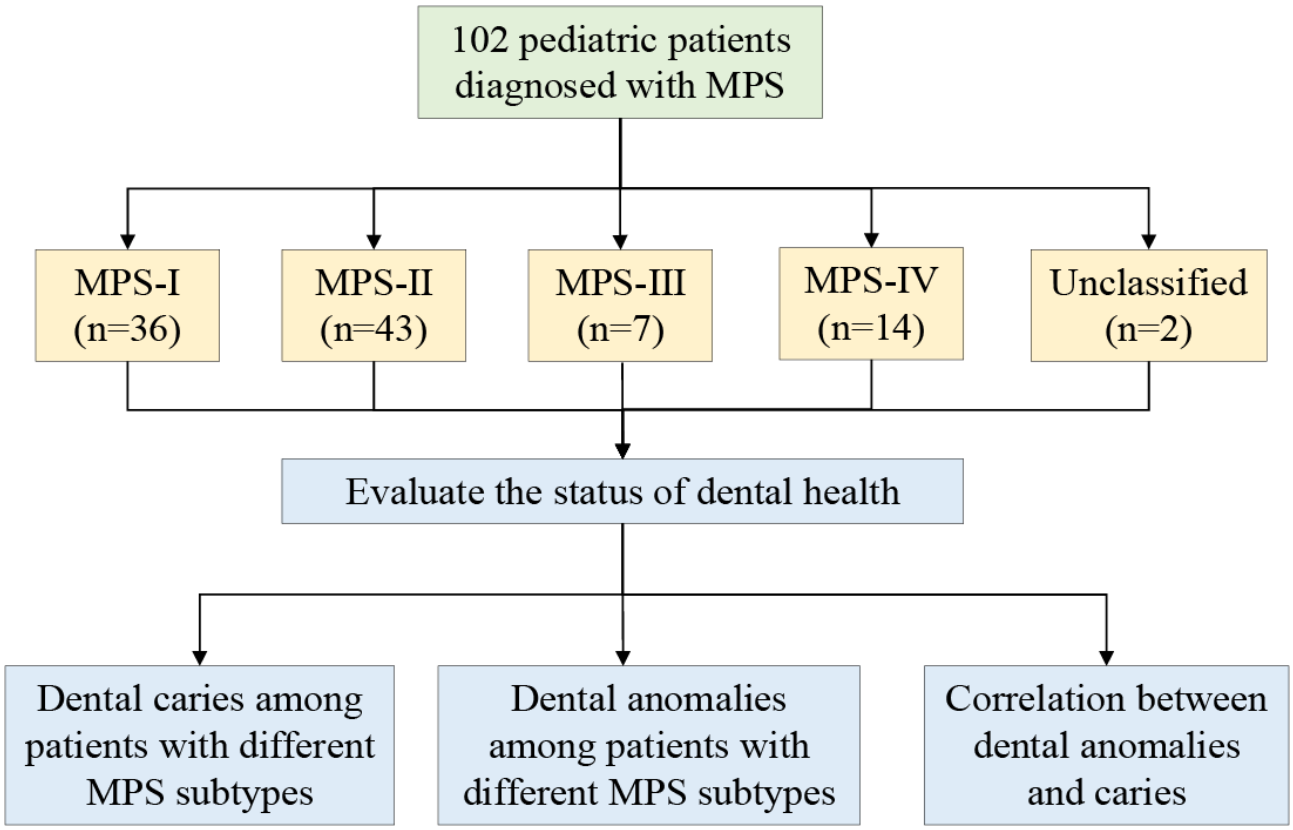
Dental anomalies were categorized into developmental (delayed or retained eruption, delayed tooth germ formation, delayed tooth development, and prolonged retention of primary teeth), morphological (conoid teeth, taurodontism, enamel hypoplasia, and microdontia), numerical (hypodontia and supernumerary teeth), positional (ectopic eruption, impaction, diastema, tooth inversion, and migration), and occlusal abnormalities (biprotrusion, crossbite, crowding, and spaced arches) [8]. Root developmental features (delayed formation, dilaceration, and elongated roots) and periodontal conditions (bone rarefaction and radiolucent lesions) were documented alongside dental follicle abnormalities.

Caries assessment used standardized diagnostic criteria through the International Caries Detection and Assessment System (ICDAS) [18] and the decayed, missing, and filled teeth index (dmft) [19]. All ICDAS codes were assigned based on standardized clinical intraoral visual examination. Lesion characteristics were recorded in terms of frequency (per-arch counts), anatomical distribution (maxillary or mandibular and anterior or posterior), and progression depth (ICDAS scores 1 - 6). All clinical examinations were performed by attending dentists as part of routine patient care over the study period. Consequently, multiple examiners were involved. While formal, prospective interexaminer calibration specific to this study was not feasible due to its retrospective design, the consistent use

XSL•FO
RenderX

of the ICDAS and dmft criteria across the department provided a standardized framework for diagnosis and recording. In addition, a single primary investigator reviewed all original clinical notes. Any ambiguous, inconsistent, or missing entries were coded as “data missing” rather than inferred to avoid interpretation bias.

Statistical Analysis



All statistical analyses were performed using R software (version 4.3.2; R Foundation for Statistical Computing). Continuous variables were described using mean (SD), while categorical variables were summarized using frequency (percentage). The normality of continuous variables was assessed using the Shapiro-Wilk test. Differences in the prevalence of dental caries and anomalies among MPS subtypes were analyzed with the chi-square or Fisher exact test. The Kruskal-Wallis test was used to compare the dmft index across subtypes. Where these tests revealed a statistically significant difference, post hoc pairwise comparisons were carried out to identify the specific pairs of subtypes that differed. Multivariable logistic regression was employed to evaluate the association between different MPS subtypes and dental health after adjusting for age and gender. Odds ratios (ORs) with 95% CIs were calculated to quantify effect sizes. A *P* value of less than .05 was considered statistically significant.

Results

Participant Characteristics

A total of 102 patients with MPS were included in this study (Figure 1), and their baseline demographic and clinical characteristics are presented in Table 1. Of these, 73.5% (75/102) were male, with a mean age of 4.8 (SD 2.6) years, ranging from 1 to 12.9 years. Regarding the age at diagnosis, 42.2% (43/102) of patients were aged 3 years or younger, 36.3% (37/102) were aged between 4 and 6 years, and 21.6% (22/102) were aged 7 years or older. MPS-II was the most common subtype (43/102, 42.2%), followed by MPS-I (36/102, 35.3%), while MPS-IV and MPS-III accounted for 13.7% (14/102) and 6.9% (7/102), respectively. Two cases (2/102, 2%) were unclassified. In terms of oral health status, the mean dmft index of the cohort was 2.7 (SD 3.4), with dental caries experience observed in 55.9% (57/102) of patients. Dental anomalies were detected in 32.4% (33/102) of the patients.

MPS Subtypes and Dental Caries

Table 2 presents the detailed characteristics of dental caries among patients with different MPS subtypes. There was no statistically significant difference observed across the MPS subtypes in dental caries (*P*=.72). Specifically, caries prevalence was 58.3% (21/36) in MPS-I, 51.2% (22/43) in MPS-II, 71.4% (5/7) in MPS-III, and 50% (7/14) in MPS-IV.

A total of 279 carious teeth were recorded. Patients with MPS-II had the highest number of carious teeth, followed by MPS-I, MPS-IV, and MPS-III. The majority of carious teeth were deciduous across all groups. By tooth type, molars were the most commonly affected, particularly in MPS-IV (35 carious molars among 7 patients) and MPS-II (66 carious molars among 22 patients). Carious lesions were more frequently observed in the maxillary teeth than in the mandibular teeth in all groups except MPS-IV.

For the dmft index, MPS-II showed the highest value (mean 5.68, SD 3.47), while MPS-III had the lowest (mean 2.40, SD 2.51). No statistically significant difference was observed among the 4 subtypes (*P*=.15). Further analysis of caries severity showed that the d4-6mft (deep dentinal lesions) were observed in 40.2% (41/102) of the participants and contributed the most to the total dmft score. Molar teeth had the highest mean dmft values in patients with MPS-IV (mean 5.00, SD 2.45), whereas patients with MPS-II exhibited the highest caries experience in maxillary teeth (mean 3.55, SD 1.99).

[c]Not applicable.

[d]dmft: decayed, missing, and filled teeth.

MPS Subtypes and Dental Anomalies

Table 3 summarizes the prevalence and types of dental anomalies across different MPS subtypes. The overall prevalence of dental anomalies was 32.4% (33/102), with a statistically significant difference among MPS subtypes (*P*=.005). A post hoc analysis revealed a statistically significant difference between MPS-II and MPS-IV (*P*=.007). Patients with MPS-IV exhibited the highest prevalence of dental anomalies (9/14, 64.3%), followed by MPS-I (15/36, 41.7%), MPS-III (2/7, 28.6%), and MPS-II (7/43, 16.3%). No anomalies were detected in the 2 (100%) patients with unclassified MPS.

Table . Dental anomalies in patients with different types of mucopolysaccharidosis (MPS).

Characteristics	MPS-I (n=36), n (%)	MPS-II (n=43), n (%)	MPS-III (n=7), n (%)	MPS-IV (n=14), n (%)	Unclassified (n=2), n (%)	*P* value[a]
Total anomalies	15 (41.7)	7 (16.3)	2 (28.6)	9 (64.3)	0 (0)	.005

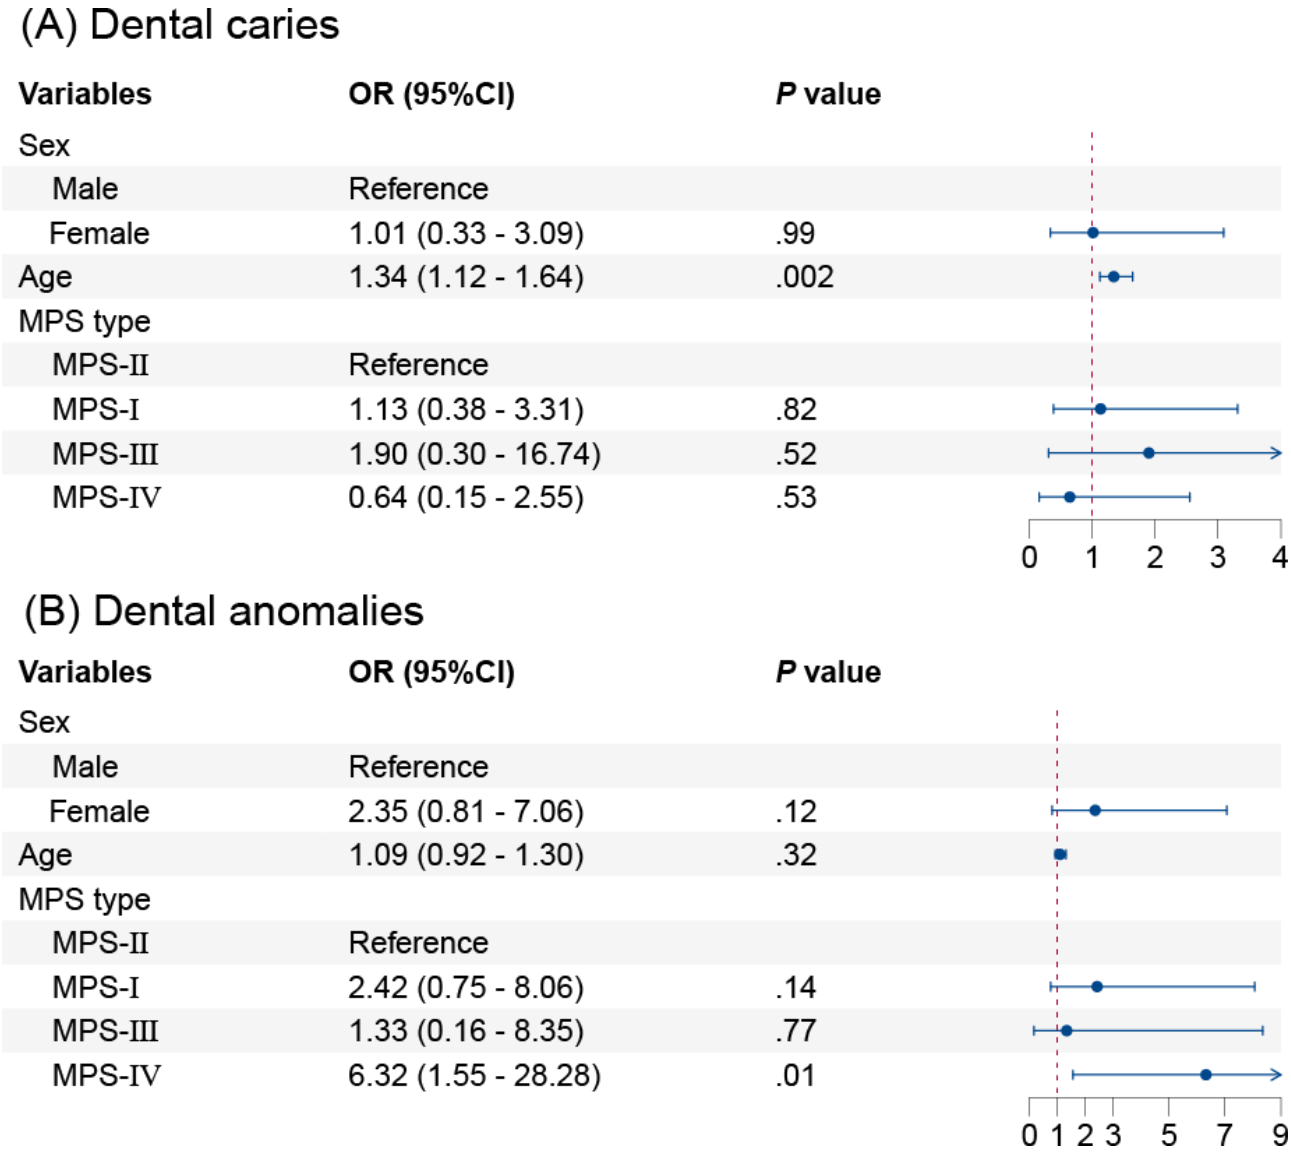
[b]Not applicable.

XSL•FO
RenderX

Developmental anomalies were the most common type observed in patients with MPS-I (9/36, 25%), while morphological anomalies were notably frequent in patients with MPS-IV (4/14, 28.6%). Patients with developmental anomalies primarily exhibited the following 4 manifestations: delayed or retained eruption, delayed tooth germ formation, delayed tooth development, and prolonged retention of primary teeth. Among these, delayed tooth germ formation occurred exclusively in patients with MPS-II, and delayed tooth development was only observed in patients with MPS-I and MPS-II. Only one 9-year-old patient (2.8%) with MPS-I presented with 3 types of developmental anomalies simultaneously, and all other patients (97.2%) exhibited only 1 type. Among patients with morphological anomalies, one 9-year-old patient with MPS-IV (14.3%) exhibited conoid teeth in 2 maxillary permanent molars, while all other cases (85.7%) presented with enamel hypoplasia.



Numerical anomalies were observed only in patients with MPS-III (1/7, 14.3%) and MPS-IV (1/14, 7.1%). All patients with numerical anomalies exhibited missing teeth. Positional anomalies were present in patients with MPS-I (3/36, 8.3%) and MPS-III (1/7, 14.3%), whereas root anomalies were rare and detected in only 1 (2.3%) patient with MPS-II. Among all patients with positional anomalies, one case presented with an anterior crossbite, while the others exhibited malposition of unerupted teeth. The patient with root anomalies (MPS-II) showed root dilaceration. Bone anomalies were most prevalent in patients with MPS-I (7/36, 19.4%), and follicle anomalies were exclusively found in patients with MPS-I (2/36, 5.6%) and MPS-II (2/43, 4.7%). Patients with bone anomalies primarily presented with radiolucent bone lesions and condylar resorption. Those with follicle anomalies mainly exhibited large dental follicles.

Multivariable Analysis of the Association of MPS Subtypes With Dental Health

Multivariable logistic regression analysis was used to evaluate the association between MPS subtypes and dental health outcomes after adjusting for sex and age. Patients with MPS-II were the most prevalent and were therefore designated as the reference group. No significant association was observed between MPS subtypes and dental caries. In contrast, patients with MPS-IV had a significantly higher risk of dental anomalies compared to those with MPS-II (OR 6.32, 95% CI 1.55 - 28.28; *P*=.01; Figure 2).

XSL•FO
RenderX

Figure 2. Multivariable analysis of the association of mucopolysaccharidosis (MPS) subtypes with dental health: (A) dental caries and (B) dental anomalies. OR: odds ratio.

Relationship Between Dental Anomalies and Dental Caries in Patients With MPS

The relationship between dental anomalies and dental caries in patients with MPS is presented in Table 4. No significant difference was observed in the prevalence of total dental anomalies between patients with and without caries (33.3% vs 31.1%; *P*=.81). Similarly, the presence of developmental anomalies was not significantly associated with dental caries (15.8% vs 13.3%; *P*=.73).

However, morphological anomalies were significantly less frequent in patients with dental caries compared to those without (3.5% vs 17.8%; *P*=.04), with an OR of 0.17 (95% CI 0.02 - 0.72). In contrast, bone anomalies were significantly more common among patients with caries (19.3% vs 2.2%; *P*=.008). The odds of having dental caries were approximately 10.5 times higher in patients with bone anomalies (95% CI 1.3 - 84.93).

Table . Relationship between dental anomalies and dental caries in patients with mucopolysaccharidosis.

Dental anomalies	Without dental caries (n=45), n (%)	With dental caries (n=57), n (%)	*P* value	OR[a] (95% CI)
Total anomalies	14 (31.1)	19 (33.3)	.81	1.11 (0.48 - 2.56)
Developmental anomalies	6 (13.3)	9 (15.8)	.73	1.22 (0.4 - 3.91)
Morphological anomalies	8 (17.8)	2 (3.5)	.04	0.17 (0.02 - 0.72)
Bone anomalies	1 (2.2)	11 (19.3)	.008	10.52 (1.3 - 84.93)

[a]OR: odds ratio.

Discussion

This retrospective analysis of 102 pediatric patients with MPS in China revealed distinct oral health characteristics across MPS subtypes. The primary findings include an overall dental caries prevalence of 55.9% (57/102), with no significant differences among subtypes (*P*=.72). In contrast, dental anomalies were observed in 32.4% (33/102) of patients, showing significant subtype-specific variation (*P*=.005), with the highest prevalence in MPS-IV (9/14, 64.3%). Further analysis indicated that deep dentinal lesions (d4-6mft) contributed the most to the total dmft score, and molars were the most frequently affected teeth.

These findings are significant because they systematically characterize oral phenotypic variability among MPS subtypes in a Chinese pediatric population for the first time. The subtype-specific distribution of dental anomalies suggests that the underlying pathophysiology of MPS may differentially affect odontogenesis, while the relatively uniform caries prevalence indicates that common risk factors, such as impaired oral hygiene maintenance, may transcend subtype-specific differences. This understanding can assist clinicians in developing tailored oral health management strategies for different MPS subtypes.

Our findings align with and extend the existing body of evidence regarding oral manifestations in patients with MPS. The overall dental caries prevalence of 55.9% (57/102) observed in our cohort corresponds with previous reports of elevated caries experience in this population. For instance, a Brazilian cross-sectional study documented significantly higher caries rates among patients with MPS relative to unaffected individuals [20,21], while a study of Indian children reported increased caries indices in both deciduous and permanent dentitions in the MPS group compared to healthy controls [22]. Similarly, individuals with rare genetic disorders, including MPS, have been shown to possess a substantially elevated likelihood of developing dental caries [23]. Notably, our observation of a predominance of deep dentinal caries adds granularity to these earlier reports, suggesting that MPS-specific factors—such as enamel structural alterations, restricted mouth opening, and functional limitations—may predispose patients to more advanced carious lesions.

Regarding dental anomalies, our results corroborate the established understanding that such abnormalities are a frequent component of the MPS phenotype. Carneiro et al [8] highlighted a range of common radiographic findings in patients with MPS, including supernumerary teeth, peg-shaped teeth, taurodontism, tooth impaction, and dilated dental roots. This is consistent with the spectrum of anomalies identified in our cohort. Further supporting this pattern, Almeida-Barros et al [16] reported supernumerary teeth in 23.5% of patients with MPS-IV and MPS-VI, and another cross-sectional study noted a high frequency of cyst-like dental crypts, taurodontism, and tooth impaction among patients with MPS [21]. The convergence of these international findings underscores that dental anomalies are a core, recurrent feature across diverse MPS populations, likely stemming from the underlying disruption of craniofacial and dental development by GAG accumulation.

A key contribution of our study lies in the comparative analysis across MPS subtypes. We found no statistically significant difference in caries prevalence or the dmft index among subtypes, suggesting that universal risk factors, such as the profound challenges in maintaining oral hygiene common to all patients with MPS, may outweigh potential subtype-specific pathophysiological differences in caries susceptibility. This homogeneity contrasts with the distinct subtype-specific pattern observed for dental anomalies, particularly the significantly higher burden in patients with MPS-IV. This divergence indicates that while caries risk may be broadly elevated across MPS due to common functional limitations, the development of specific dental anomalies is more closely linked to the particular skeletal and developmental pathology of each subtype.

Although we attribute the subtype-specific differences in dental anomalies primarily to the severe skeletal dysplasia characteristic of MPS-IV, alternative explanations should be considered. Variability in medical management, such as the timing and availability of enzyme replacement therapy, across subtypes may indirectly influence oral and dental development. Additionally, differences in the average age at dental examination among subtypes could affect the detection rate of certain anomalies, particularly those associated with tooth eruption and development.

The clinical implications of this study are 3-fold. First, patients with MPS-IV should be prioritized for early and comprehensive screening of dental anomalies to allow for timely orthodontic intervention. Second, all patients with MPS require intensified caries prevention strategies, with particular emphasis on pit and fissure sealing of molars. Third, those subtypes with significant neurocognitive impairment, such as MPS-III, necessitate the development of adapted oral hygiene aids and caregiver-assisted protocols. These findings support the integration of standardized oral evaluation into the multidisciplinary management framework for MPS.

Several limitations warrant careful consideration. First, the retrospective design and extraction of dental data from historical clinical records introduce potential information bias. As multiple dentists conducted examinations over the 15-year study period without formal interexaminer calibration, variations in diagnostic thresholds and recording practices are possible. To mitigate this, a standardized data extraction protocol aligned with ICDAS criteria was applied by a single primary investigator. Nevertheless, such nondifferential misclassification would likely have biased effect estimates toward the null. Second, the sample size remained limited for some subtypes after stratification, potentially reducing statistical power. Third, the absence of a healthy control group precluded direct comparison with the general population. Finally, unmeasured confounders, such as dietary habits and detailed oral hygiene practices, could not be accounted for.

Future studies should prioritize prospective, multicenter designs with precalibrated examiners to ensure diagnostic consistency. Incorporating objective biomarkers, salivary microbiological analysis, and standardized imaging protocols would help elucidate the mechanisms underlying caries susceptibility and dental anomalies in MPS. Moreover, longitudinal studies are

XSL•FO
RenderX

needed to evaluate the long-term effectiveness of subtype-specific preventive and therapeutic oral health interventions.

In conclusion, this study demonstrates that Chinese pediatric patients with MPS experience a substantial burden of dental caries and anomalies, with the latter showing marked subtype-specific variation. These findings underscore the necessity of subtype-tailored oral health strategies and the integration of structured dental assessment into routine MPS follow-up care to enable early detection and intervention.

Abstract

Background: The gut microbiota plays a crucial role in infant nutrition through its effects on energy metabolism, nutrient absorption, and immune regulation. However, evidence from Indonesian infants remains limited.

Objective: This study aimed to examine the association between genus-level gut microbiota abundance and weight-for-age *z* scores (WAZ) among 6-month-old infants in coastal Banggai District, Central Sulawesi, Indonesia.

Methods: We conducted a nested follow-up cross-sectional observational analysis of 88 six-month-old infants, including 42 (47.7%) who were born to mothers who were assigned to receive *Moringa oleifera* enriched with royal jelly group and 46 (52.3%) who were assigned to receive a multiple micronutrient supplement in a previous maternal supplementation trial. Maternal and infant characteristics were collected via structured interviews and standardized anthropometric measurements. WAZ was calculated using the World Health Organization Child Growth Standards, and underweight (WAZ <−2 SD) was reported as a secondary indicator. Stool samples were analyzed using genus-specific quantitative polymerase chain reaction to quantify *Bifidobacterium*, *Lactobacillus*, *Bacteroides*, *Clostridium*, and *Escherichia coli* (log_{10} colony-forming unit/mL). Associations between bacterial abundance and WAZ were assessed using multivariable linear regression adjusted for maternal supplementation allocation and relevant maternal, environmental, and infant covariates.

Results: The pooled mean WAZ was −0.47 (SD 1.09), and 8% (7/88) of the infants were underweight. The combined abundance of beneficial genera was higher than that of opportunistic bacteria (*E coli* and *Clostridium;* Wilcoxon signed-rank test; *P*=.002). Higher *Clostridium* abundance was inversely associated with WAZ (unadjusted β=−.094, 95% CI −0.173 to −0.015; *P*=.02; adjusted β=−.091, 95% CI −0.172 to −0.010; *P*=.03). No statistically significant associations were observed for *Bifidobacterium* (*P*=.13), *Lactobacillus* (*P*=.19), *Bacteroides* (*P*=.70), or *E coli* (*P*=.18) in adjusted models.

Conclusions: Among 6-month-old infants in coastal Central Sulawesi, higher genus-level *Clostridium* abundance was independently associated with lower WAZ. Given the cross-sectional design and genus-level quantitative polymerase chain reaction assessment, temporality and species-level mechanisms cannot be established. Longitudinal studies using more comprehensive microbiome profiling are warranted to clarify potential pathways linking gut microbiota and early-life growth.

KEYWORDS

Clostridium; gut microbiota; weight-for-age z score; infants; Indonesia

Introduction

The growth of infants aged 0 to 6 months represents a critical period that is strongly influenced by nutritional status. One of the most sensitive indicators for assessing nutritional status is the weight-for-age *z* score (WAZ), where values below −2 SD are classified as underweight. Undernutrition, which may result from stunting, wasting, or both, is reflected by being underweight and contributes substantially to morbidity,

XSL•FO
RenderX

mortality, and long-term developmental impairments in early life [1,2].

Globally, the prevalence of underweight among children under 5 has declined considerably over the past decades. According to the World Bank's World Development Indicators, derived from the Joint Child Malnutrition Estimates, the global prevalence has decreased from approximately 25% in the early 1990s to around 12% to 13% in recent years [3]. In Indonesia, the 2024 Indonesian Nutrition Status Survey reported a prevalence of 14.5%, showing a decline from the previous year but still above the national target [4]. At the regional level, disparities persist, with the 2023 Indonesian Health Survey reporting an underweight prevalence of 24.4% in Central Sulawesi and 22.7% in Banggai District [5]. This prevalence exceeds the World Health Organization (WHO) threshold for a high public health burden (20% - 29%), indicating a persistent challenge for child nutrition in these areas.

Although these figures illustrate the magnitude of the problem, understanding the underlying biological and environmental determinants remains essential. In addition to inadequate dietary intake and infectious diseases, recent scientific evidence has highlighted the critical role of the gut microbiota in shaping infant nutritional status. The gut microbiota influences energy metabolism, nutrient absorption, and immune regulation [6,7]. Emerging studies have shown that early-life variations in microbiota composition can affect linear growth and the risk of undernutrition [8]. Reviews have also emphasized the close link between microbial diversity, immune system maturation, and overall infant health [9,10].

Several studies have demonstrated associations between gut microbiota dysbiosis and growth impairment. Research in Bangladesh and Malawi found that children with growth faltering generally had lower levels of *Bifidobacterium* and *Lactobacillus*, along with a higher abundance of opportunistic bacteria such as *Enterobacteriaceae* [11-13]. Similarly, a study in Finland reported that probiotic supplementation could restore microbiota balance and promote infant growth [14]. However, evidence from Indonesia remains limited, particularly in coastal regions such as Central Sulawesi, where nutritional challenges and environmental exposures may influence early-life microbial colonization.

Moreover, most previous studies have primarily focused on stunting, while limited research has examined the association between gut microbiota balance and WAZ during early infancy. Therefore, this study aimed to examine the association between genus-level gut microbiota abundance and WAZ among 6-month-old infants in coastal Banggai District, Central Sulawesi, Indonesia.

Methods

Study Design and Setting

This study was a nested follow-up cross-sectional observational analysis of infants born to mothers who had previously participated in a randomized maternal supplementation trial conducted in coastal areas of Banggai District, Central Sulawesi, Indonesia, specifically in the rural subdistricts of Batui Selatan and Moilong. In the original trial, pregnant women were randomly assigned to receive either multiple micronutrient supplements (MMS) in accordance with national guidelines or *Moringa oleifera* enriched with royal jelly (MRJ) during pregnancy. Supplementation was provided from the second trimester until delivery (September 2023-June 2024).

This study used follow-up data from the infant cohort to examine the association between gut microbiota composition and infant nutritional status at 6 months of age, measured using WAZ. Because the infants originated from the previous maternal supplementation trial, the original supplementation allocation (MRJ vs MMS) was considered in the statistical analysis to account for potential confounding. This study did not evaluate the efficacy of the maternal supplementation intervention and did not involve new randomization or intervention during infancy. The original trial was not registered in a public trial registry; therefore, this manuscript is reported as a nested observational follow-up analysis rather than as a primary randomized trial report.

Follow-up data collection was conducted between August and December 2024 through household visits. Anthropometric measurements and questionnaire-based information on maternal, infant, and environmental characteristics were obtained, and infant fecal samples were collected for microbiota analysis. Laboratory analyses of the fecal samples were completed by April 2025 at a university-affiliated medical research center. Reporting followed the STROBE (Strengthening the Reporting of Observational Studies in Epidemiology) guideline for cross-sectional studies because this manuscript reports a nested observational follow-up analysis rather than the primary outcomes of the original randomized trial (Checklist 1).

Participants

Infants included in this study were born to mothers who had participated in the original randomized controlled trial of maternal supplementation. In that trial, 160 pregnant women were randomly assigned to receive either the MRJ supplement—a daily capsule containing *M oleifera* leaf extract enriched with royal jelly—or a standard MMS in accordance with national guidelines. Supplementation was provided from the second trimester until delivery (September 2023-June 2024).

During the follow-up phase (August-December 2024), infants were assessed when they reached 6 months of age. The follow-up analysis focused specifically on infants at 6 months of age. Infants who had already exceeded 6 months of age at the time of follow-up or whose families had relocated outside the study area were not included in the analysis. Because the outcome assessment was restricted to infants aged 6 months, anthropometric measurements were not obtained for those who were not eligible for follow-up. A total of 88 infants met the inclusion criteria and were enrolled in this analysis (n=42, 47.7% from the MRJ group and n=46, 52.3% from the MMS group).

Ethical Considerations

This study was approved by the ethics committee of the Faculty of Public Health, Hasanuddin University (protocol code 281024093076; approval 3505/UN4.14.1/TP.02.02/2024).

XSL•FO
RenderX

Written informed consent was obtained from all participants prior to enrollment.

Sample Size Considerations

The sample size for this nested follow-up analysis was determined by the number of infants who met the predefined eligibility criteria (assessment at 6 months of age) and were available during the follow-up period, rather than by an a priori sample size calculation for microbiota outcomes. To contextualize statistical power, a post hoc assessment indicates that with 88 participants and a 2-sided α level of .05, the study has approximately 80% power to detect a moderate association (equivalent to a correlation of r=0.30) in unadjusted analyses. We acknowledge that power may be lower in multivariable models after adjustment for multiple covariates; therefore, smaller associations may not have been detected, and nonsignificant findings for some genera should be interpreted cautiously.

Variables and Outcomes

The primary outcome was infant nutritional status assessed using WAZ based on the WHO Child Growth Standards (2006) and analyzed as a continuous variable. Underweight (WAZ<−2 SD) was defined and reported as a secondary descriptive indicator. The primary exposure variable was gut microbiota composition at 6 months of age, focusing on 5 bacterial genera: *Bifidobacterium*, *Lactobacillus*, *Bacteroides*, *Clostridium*, and *Escherichia coli*. Potential covariates included infant sex, birth weight, mode of delivery, maternal age and education, household socioeconomic status, breastfeeding practices, and the maternal supplementation group (MRJ or MMS).

Data Collection

Data were collected during home visits conducted by the research team in collaboration with trained enumerators. Structured questionnaires were administered to obtain information on maternal and infant characteristics, feeding practices, and sociodemographic factors. Following the interviews, anthropometric measurements of the infants were taken using calibrated equipment and standardized procedures, with assistance from the enumerators. In addition, fecal samples were collected from the infants for subsequent microbiota analysis.

Anthropometric Measurements

Anthropometric assessments were performed when infants reached 6 months of age. Weight was measured using a calibrated digital infant scale, and recumbent length was recorded as supplementary information. Measurements were taken twice; if discrepancies were detected, a third measurement was performed, and the mean of the 2 closest values was used in the analysis. WAZ values were calculated using WHO Anthro software (version 3.2.2), and underweight was defined as WAZ<−2 SD according to WHO standards.

Gut Microbiota Analysis

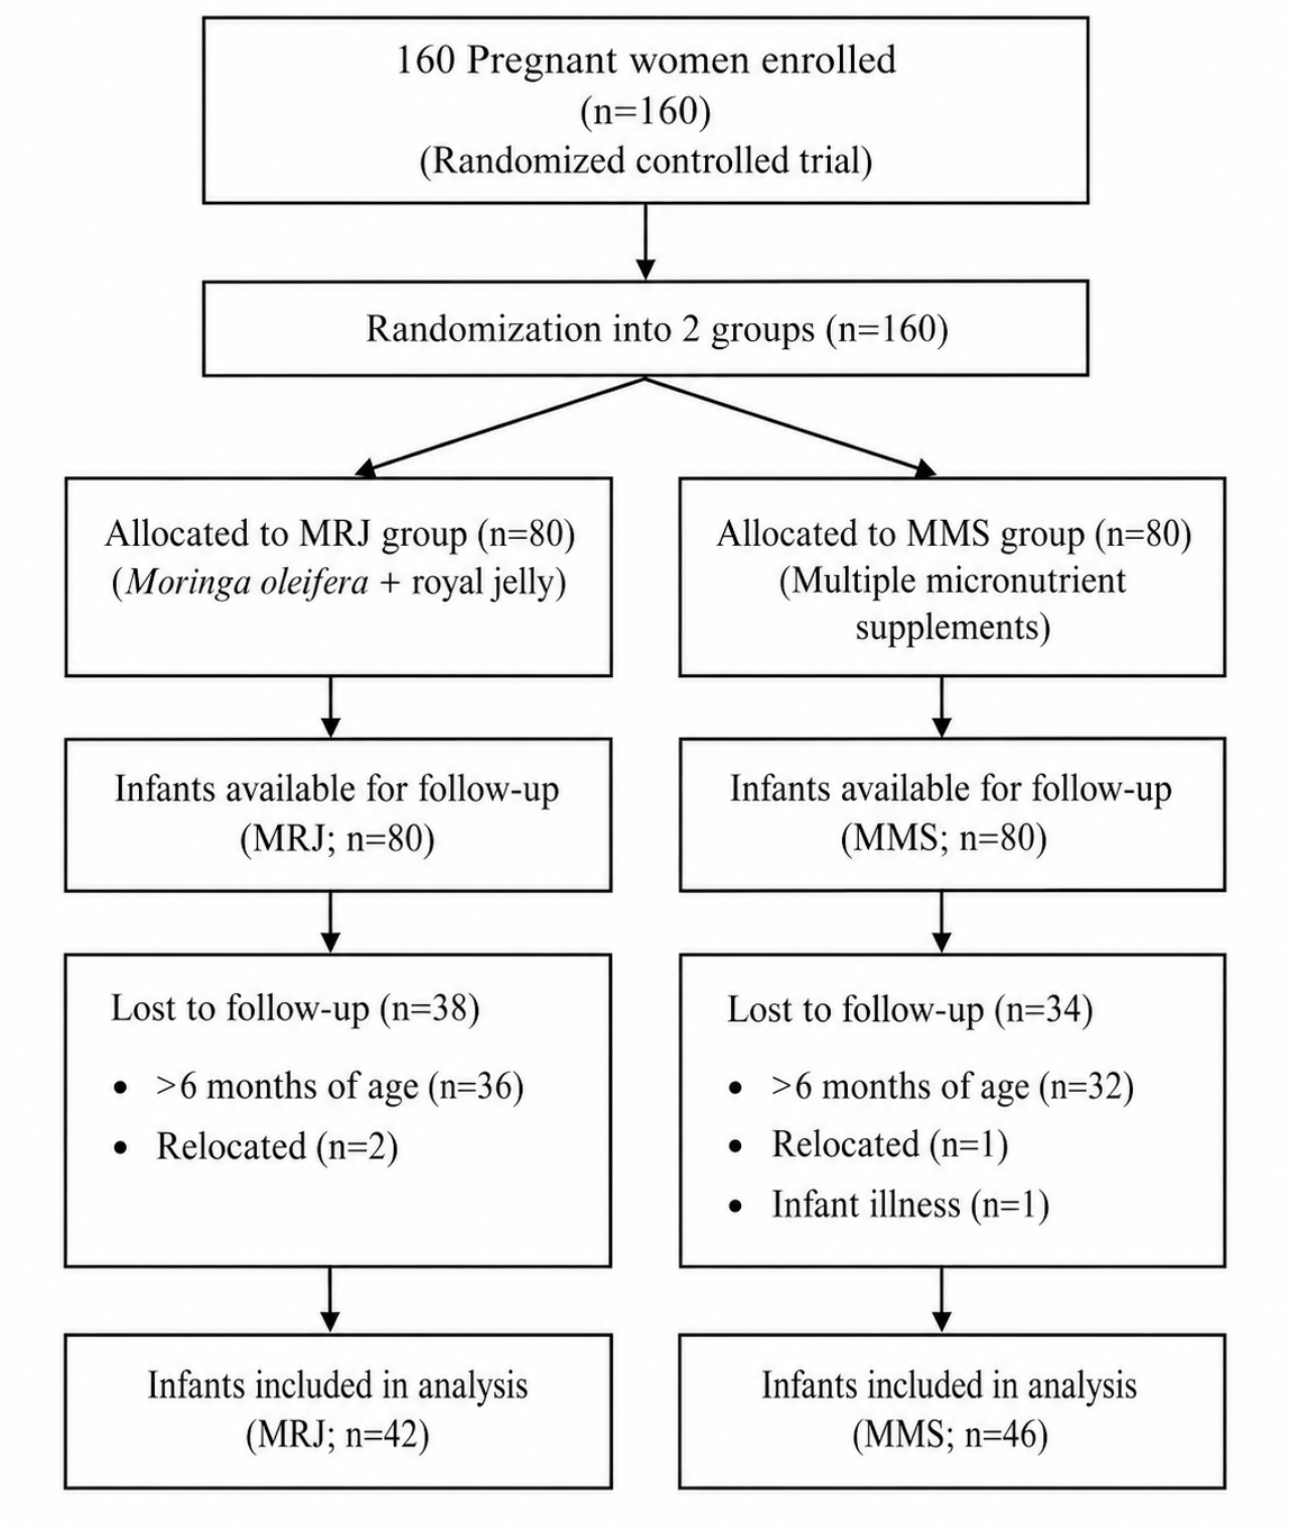
Fecal samples were stored at −20 °C and analyzed at the Hasanuddin University Medical Research Center. DNA was extracted using the Presto Stool DNA Extraction Kit (Geneaid Biotech Ltd) following the manufacturer's protocol. Quantitative analysis of gut microbiota was performed using quantitative polymerase chain reaction (qPCR) with genus-specific primers targeting *Bifidobacterium*, *Lactobacillus*, *Bacteroides*, *Clostridium*, and *E coli*. Results were expressed as $\log_{10}$ colony-forming units (CFU)/mL. Additional laboratory details for DNA extraction and genus-level qPCR procedures are provided in Multimedia Appendix 1.

Statistical Analysis

Data were analyzed using SPSS software (version 23; IBM Corp). Descriptive statistics were used to summarize maternal, infant, environmental, and microbiota characteristics. The Shapiro-Wilk test was applied to assess normality. Group comparisons between supplementation groups were performed using the chi-square test for categorical variables and the Mann-Whitney U test for continuous variables with nonnormal distributions. Paired differences in bacterial abundance within the same infants were assessed using the Wilcoxon signed-rank test. Associations between gut bacterial abundance ($\log_{10}$ CFU/mL) and WAZ were examined using multivariable linear regression models.

There were no missing data for variables included in the regression models; therefore, all regression analyses used n=88. Covariates were selected a priori based on biological plausibility and evidence from previous studies as potential confounders of the microbiota-growth relationship, including maternal supplementation group (MRJ vs MMS), maternal education, environmental health status, gestational age at birth, mode of delivery, infant illness history within the first 6 months, immunization status, exclusive breastfeeding, and birth weight category. To maintain parsimony given the modest sample size, we used this prespecified covariate set and fitted separate adjusted models for each bacterial genus (ie, without data-driven covariate selection procedures). Linear regression assumptions were evaluated using residual diagnostics for linearity and homoscedasticity and Q-Q plots for normality of residuals. Multicollinearity among covariates was assessed using variance inflation factors, and influential observations were examined using standardized residuals and the Cook distance. Model fit was summarized using R^2 and adjusted R^2. All tests were 2-tailed, and statistical significance was set at P<.05.

Results



Characteristics of Study Participants

A detailed participant flow diagram is presented in Figure 1. A total of 88 six-month-old infants were included in the analysis (n=42, 47.7% MRJ and n=46, 52.3% MMS). Baseline household, maternal, and infant characteristics are summarized in Table 1. Maternal and paternal education were categorized as low (primary and junior secondary school) and high (senior secondary school or higher, including diploma and university). Most baseline characteristics were comparable between groups; however, the MRJ group had a higher proportion of fathers with low education than the MMS group (15/42, 35.7% vs 6/46, 13%; P=.01), and households in the MMS group more often reported a drinking water source within ≤10 m (12/46, 26.1% vs 3/42, 7.1%; P=.02). Infant sex distribution also differed

XSL•FO
RenderX

between groups (male infants: 26/46, 56.5% in MMS vs 14/42, 33.3% in MRJ; *P*=.03). Anthropometric outcomes at 6 months were similar between groups, including WAZ (*P*=.63). Overall, mean WAZ in the pooled sample was −0.47 (SD 1.09), and 8% (7/88) were classified as underweight. These pooled data were used in subsequent analyses to examine associations between gut microbiota composition and growth outcomes.

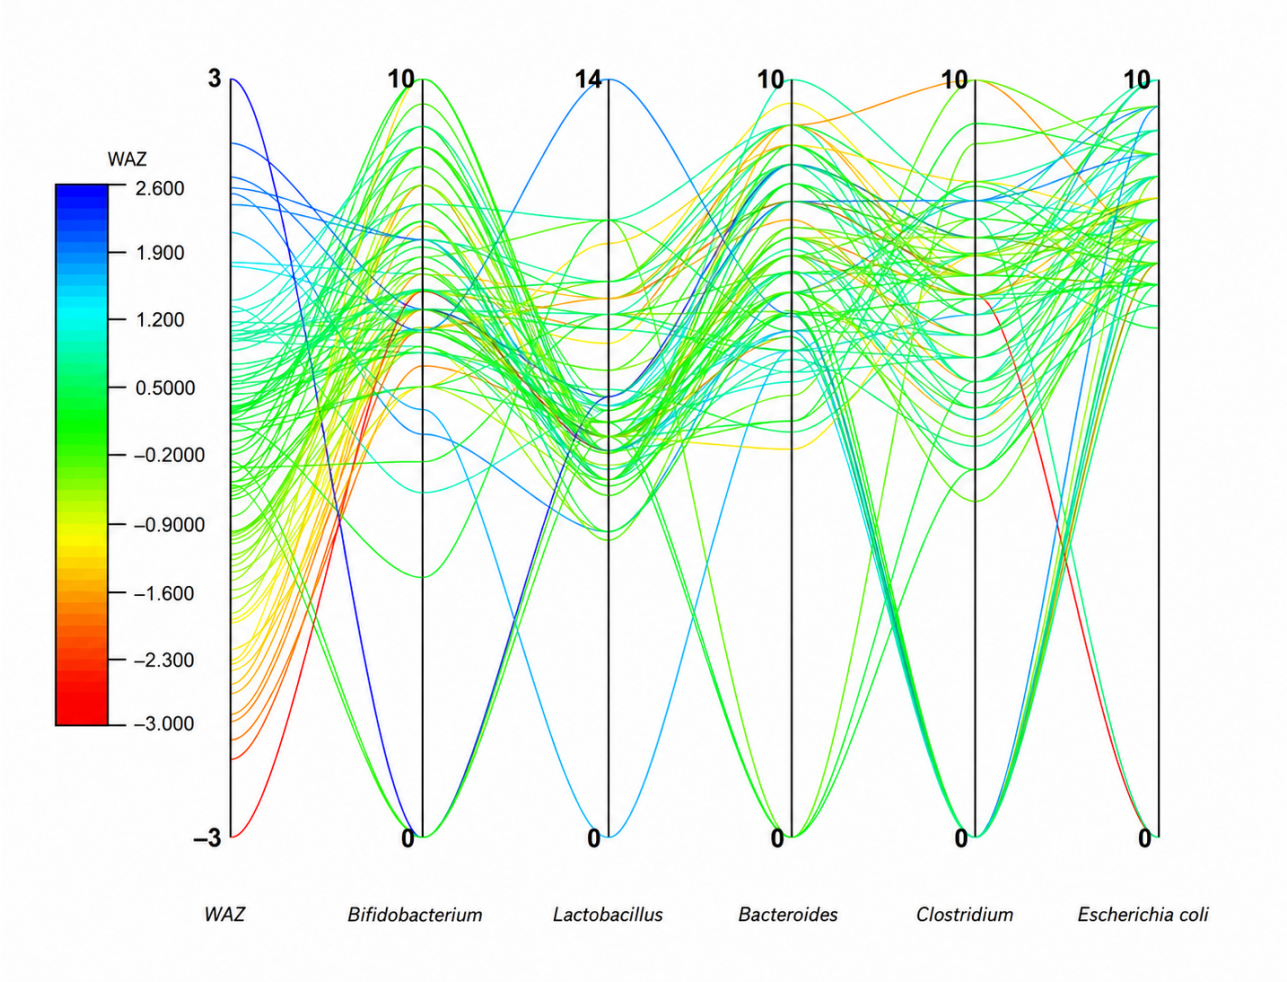
Gut Microbiota Composition and Distribution by Nutritional Status in 6-Month-Old Infants

The gut microbiota composition of 6-month-old infants is summarized in Table 2. Among the beneficial bacterial genera, *Lactobacillus* exhibited the highest mean concentration (mean 7.83, SD 1.75 log CFU/mL), followed by *Bifidobacterium* (mean 7.44, SD 1.88 log CFU/mL). The commensal genus *Bacteroides* was detected at comparable levels (mean 7.52, SD 1.82 log CFU/mL). In contrast, the mean concentrations of opportunistic bacteria were 8.03 (SD 1.43) log CFU/mL for *E coli* and 6.00 (SD 2.73) log CFU/mL for *Clostridium*. When grouped, the combined abundance of beneficial bacteria (*Bifidobacterium* and *Lactobacillus*) was significantly higher than that of opportunistic bacteria (*E coli* and *Clostridium;* mean 7.64, SD 1.36 vs mean 7.01, SD 1.82 log CFU/mL; Wilcoxon signed-rank test: *Z*=1204.5; *P*=.002).

Table . Gut microbiota composition of 6-month-old infants (n=88, log colony-forming unit [CFU]/mL).



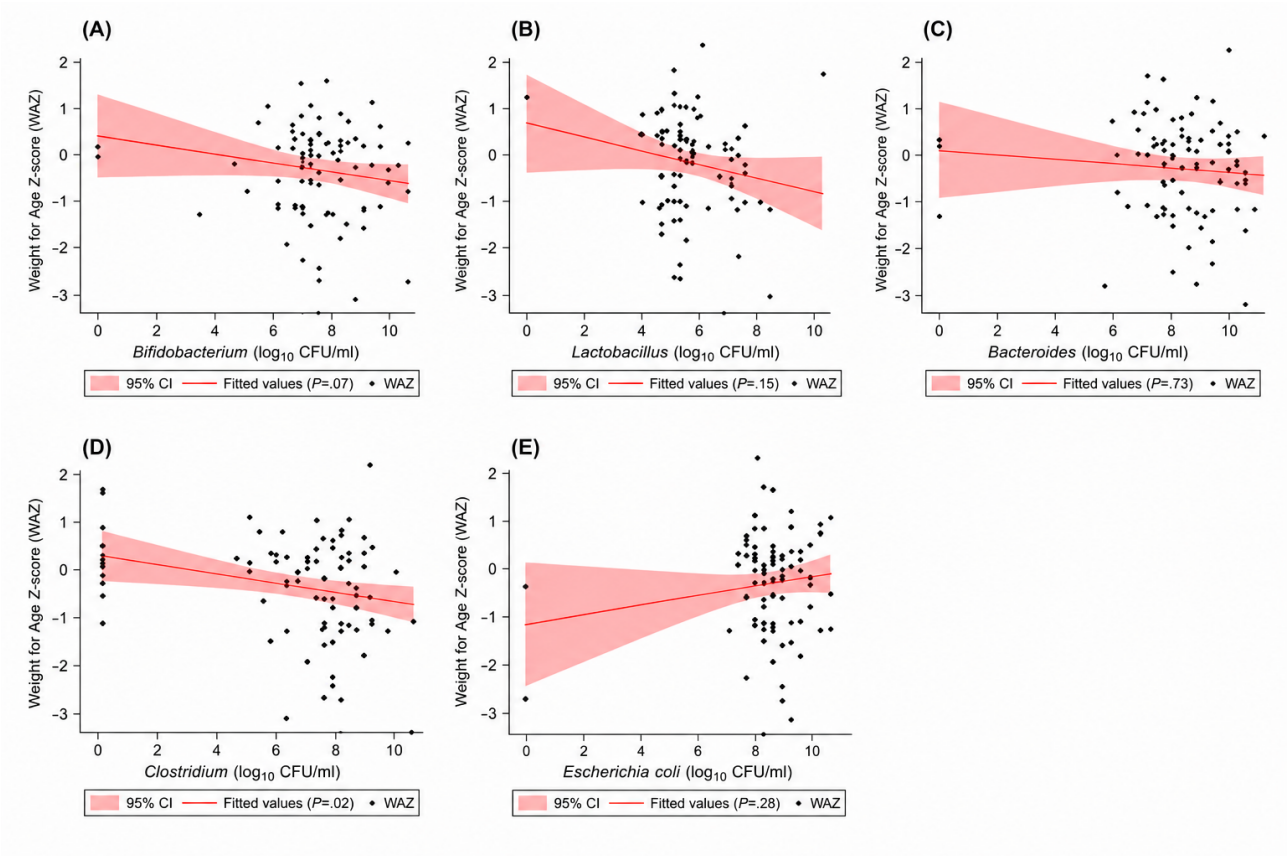
Gut microbiota	Values, mean (SD)	Values, median (IQR)
Bifidobacterium (beneficial)	7.44 (1.88)	7.69 (6.98 - 8.51)
Lactobacillus (beneficial)	7.83 (1.75)	7.78 (6.50 - 9.27)
Bacteroides (commensal)	7.52 (1.82)	7.54 (6.77 - 8.26)
Clostridium (opportunistic)	6.00 (2.73)	7.03 (5.55 - 8.12)
Escherichia coli (opportunistic)	8.03 (1.43)	7.84 (7.27 - 8.70)
Beneficial bacteria[a]	7.64 (1.36)	7.69 (6.98 - 8.51)
Opportunistic bacteria[a]	7.01 (1.82)	7.44 (5.89 - 8.12)

[a]Wilcoxon signed-rank test (beneficial vs opportunistic bacteria): *Z*=1204.5; *P*=.002.

Figure 2 illustrates the distribution of the 5 dominant bacterial genera (*Bifidobacterium*, *Lactobacillus*, *Bacteroides*, *Clostridium*, and *E coli*) according to infant nutritional status. Each line in the figure represents an individual infant, and the color gradient indicates WAZ, ranging from very low values (red, <–3 SD) to high values (blue, approaching 2 SD). Infants with lower WAZ demonstrated greater variability in microbial abundance, particularly for *Lactobacillus* and *Clostridium*. Conversely, infants with normal or higher WAZ values exhibited more uniform distribution patterns across the analyzed genera. These results indicate that underweight infants tended to present more heterogeneous gut microbiota profiles, whereas well-nourished infants showed a more balanced bacterial composition.

XSL•FO
RenderX

Figure 2. Parallel coordinates plot of genus-level gut microbiota abundance (log_{10} colony-forming unit [CFU]/mL) and weight-for-age *z* scores (WAZ) in 6-month-old infants (n=88). Each line represents one infant. Line color indicates WAZ (red=lower WAZ; blue=higher WAZ; observed range −3.0 to 2.6). Vertical axes show WAZ and bacterial genus abundance measured by quantitative polymerase chain reaction.



Association Between Gut Microbiota Genus and WAZ

The associations between gut microbiota composition and WAZ are illustrated in Figure 3. Overall, the regression patterns indicated a predominantly negative trend between bacterial abundance and WAZ across most genera. For *Bifidobacterium* (panel A) and *Lactobacillus* (panel B), the regression lines exhibited a slight downward slope, suggesting that higher levels of these bacteria were associated with lower WAZ; however, these associations were not statistically significant. *Bacteroides* (panel C) showed a nearly flat regression line, indicating a weak relationship with WAZ.

XSL•FO
RenderX

Figure 3. Scatterplots showing unadjusted associations between genus-level bacterial abundance (log_{10} colony-forming unit [CFU]/mL) and weight-for-age *z* scores (WAZ) in 6-month-old infants (n=88). Each point represents one infant. The solid line shows the fitted linear relationship and the shaded area represents the 95% CI for the fitted line. Panels (A-E) correspond to *Bifidobacterium*, *Lactobacillus*, *Bacteroides*, *Clostridium*, and *Escherichia coli*, respectively.

In contrast, *Clostridium* (panel D) demonstrated a clear negative association, with a decreasing regression line, suggesting that greater *Clostridium* abundance was related to lower WAZ. For *E coli* (panel E), the regression line indicated a positive but nonsignificant trend, which should be interpreted with caution.

Table 3 summarizes the linear regression results examining the associations between bacterial genera and WAZ among 6-month-old infants. In the unadjusted model, none of the beneficial genera (*Bifidobacterium* and *Lactobacillus*) were significantly associated with WAZ, although both demonstrated a negative trend. Similarly, *Bacteroides* and *E coli* showed no significant associations. Conversely, *Clostridium* exhibited a significant negative association with WAZ (β=–.094, 95% CI –0.173 to –0.015; *P*=.02), indicating that higher *Clostridium* abundance was linked to lower weight-for-age status. This association remained significant in the adjusted model (β=–.091, 95% CI –0.172 to –0.010; *P*=.03) after controlling for maternal, perinatal, and environmental covariates. These findings indicate that higher *Clostridium* abundance was independently associated with lower WAZ, suggesting a potential link with early-life growth faltering.

Table . Association between gut microbiota genera and weight-for-age *z* scores (WAZ) in 6-month-old infants.

Genus	Model 1[a]		Model 2[b]	
	Unadjusted β (95% CI)	*P* value	Adjusted β (95% CI)	*P* value
Bifidobacterium	–0.105 (–0.220 to 0.010)	.07	–0.090 (–0.207 to 0.027)	.13
Lactobacillus	–0.091 (–0.215 to 0.033)	.15	–0.087 (–0.218 to 0.043)	.19
Bacteroides	–0.021 (–0.139 to 0.097)	.73	–0.024 (–0.149 to 0.101)	.70
Clostridium	–0.094 (–0.173 to –0.015)	.02[c]	–0.091 (–0.172 to –0.010)	.03[c]
Escherichia coli	0.083 (–0.067 to 0.233)	.28	0.110 (–0.051 to 0.271)	.18

[a]Model 1 (unadjusted): without confounding variables.

[b]Model 2 (adjusted): after controlling for confounding variables (maternal supplementation, maternal education, environmental health, gestational age, delivery process, infant illness history, immunization status, exclusive breastfeeding, and birth outcomes).

Discussion

Principal Findings

This study found a significant inverse association between *Clostridium* abundance and WAZ among 6-month-old infants living in coastal areas of Central Sulawesi, Indonesia. This finding indicates that higher abundance of opportunistic bacteria was associated with lower WAZ and may be a marker of early-life growth faltering. In contrast, *Bifidobacterium*, *Lactobacillus*, *Bacteroides*, and *E coli* were not significantly associated with WAZ in the adjusted models. Although infants from both maternal supplementation groups (MRJ and MMS) exhibited a relatively low prevalence of underweight (7/88, 8%), mild growth faltering persisted, indicating that postnatal influences such as feeding practices, environmental exposures, and gut microbiota composition likely continue to shape infant growth outcomes beyond prenatal nutritional interventions. Because the microbiota assessment in this study included only 5 bacterial genera quantified by genus-level qPCR, interpretations should be limited to genus-level associations. Recent systematic evidence supports a broader link between gut microbiota composition and child growth outcomes, including growth faltering and stunting, although findings vary across settings and methods [15], and recent reviews emphasize the intersection of undernutrition, microbiome development, and early child health outcomes [16].

The gut microbiota plays a critical role in nutrient metabolism, immune regulation, and intestinal homeostasis during infancy. In this study, beneficial genera such as *Bifidobacterium* and *Lactobacillus* were predominant, consistent with their established roles in carbohydrate fermentation, production of short-chain fatty acids, and support of mucosal immunity [15-17]. These genera are often enriched in breastfed infants and are linked to favorable nutritional outcomes. However, neither *Bifidobacterium* nor *Lactobacillus* demonstrated significant associations with WAZ in this cohort, which may reflect limited variability within a generally adequate range and/or limited power to detect smaller effect sizes. The nonsignificant association observed for *Bifidobacterium* should be interpreted with caution and does not necessarily indicate that this genus is not relevant to infant growth. *Bifidobacterium* is widely recognized as a key early-life gut colonizer involved in human milk oligosaccharide metabolism, short-chain fatty acid production, gut barrier maturation, and immune development [16,18]. Recent evidence also supports the role of *Bifidobacterium* in infant immune development and highlights species- and strain-specific functional differences, which may not be captured by genus-level qPCR assessment [18,19]. In this study, the lack of a significant association may therefore be partly explained by the modest sample size, limited between-infant variability, cross-sectional assessment at a single time point, and the inability to distinguish species- or strain-level variation.

In contrast, *Clostridium* exhibited a robust negative association with WAZ after adjusting for maternal, perinatal, and environmental factors, including maternal supplementation allocation. This aligns with previous studies reporting that differences in the abundance of opportunistic taxa are associated with impaired intestinal barrier function, low-grade inflammation, and decreased nutrient absorption efficiency [18-21]. Recent evidence further suggests that colonization during key developmental windows may be linked to microbiota-dependent shifts in growth and immunity during undernutrition [22]. However, because our microbiota assessment was conducted at the genus level using qPCR, the observed association reflects *Clostridium* at the genus level only; species-specific composition, pathogenicity, enterotoxin production, and functional activity cannot be inferred from these data. Accordingly, mechanistic interpretations should be made cautiously, and the findings should be interpreted as an association rather than evidence of causation. Similar findings from Indonesian and other low-resource populations have linked microbial dysbiosis, including increased *Clostridium* and reduced phylogenetic diversity, with growth faltering and stunting [19,22,23]. These observations underscore the relevance of gut microbiota composition as a determinant of infant growth and metabolic health. Recent studies from Indonesia also report gut microbiota differences between children with impaired growth and those with normal growth, including findings from East Nusa Tenggara, Aceh, and urban low-income settings, supporting the relevance of microbiota-growth relationships in diverse Indonesian contexts [20,24,25]. Consistent with this, recent work also reports that stunting can be associated with persistent and potentially transferable gut microbiome alterations [26].

The predominance of beneficial bacteria in this population, alongside the observed negative effect of *Clostridium*, highlights the delicate balance between protective and pathogenic microbial communities in early life. Maintaining this balance is influenced by breastfeeding, maternal diet, hygiene, and environmental exposures. Previous trials have demonstrated that supplementation with human milk oligosaccharides promotes the growth of *Bifidobacterium* while suppressing opportunistic bacteria, resulting in improved gut maturation and growth outcomes [22,27]. Similarly, meta-analyses have shown that infant formulas supplemented with prebiotics or synbiotics beneficially modify gut microbial profiles and improve feeding tolerance and growth [28]. Furthermore, transitions from exclusive breastfeeding to mixed or complementary feeding have been shown to alter microbial diversity and metabolic activity, influencing growth trajectories during infancy [29]. The interaction between nutrition, immunity (eg, secretory IgA), and microbiota composition supports the need for integrated interventions that sustain gut health and optimal growth [30].

From a public health perspective, these findings emphasize that gut microbiota composition is not merely a biological variable but a potentially modifiable correlate of child growth and nutrition [17,22]. The observed association between *Clostridium* abundance and lower WAZ suggests that environmental and behavioral factors influencing microbial colonization, such as hygiene, breastfeeding practices, and maternal nutrition, represent actionable targets for community-based interventions [12,16,31]. The predominance of *Bifidobacterium* and *Lactobacillus* in well-nourished infants further reinforces the importance of promoting exclusive breastfeeding and dietary

XSL•FO
RenderX

diversity during lactation [32-34]. Incorporating probiotic and prebiotic strategies into maternal and child nutrition programs could enhance resilience against microbial dysbiosis and strengthen early-life growth outcomes [35,36].

Limitations

This study has several limitations. The cross-sectional design precludes causal inference, and temporality between gut microbiota composition and WAZ cannot be established. The modest sample size (n=88) may have limited statistical power to detect smaller associations, particularly in adjusted models; thus, nonsignificant findings should be interpreted cautiously. Because this analysis was nested within a prior randomized maternal supplementation trial, prenatal exposures—including supplementation adherence, maternal diet, and health during pregnancy—may have influenced infant gut microbiota through pathways not fully captured in the current models. Although supplementation allocation (MRJ vs MMS) was included as a covariate, residual confounding cannot be excluded. Maternal anthropometric data, including BMI at enrollment, were not available for this analysis and could not be adjusted for. Exclusive breastfeeding was included as a covariate; however, no dedicated subgroup analysis by breastfeeding status was conducted, and interpretations related to breastfeeding practices should therefore be made cautiously.

Furthermore, the use of qPCR quantification provides genus-level data and does not capture species-specific or functional microbial diversity. Future longitudinal studies using metagenomic and metabolomic approaches are warranted to elucidate the mechanistic pathways linking gut microbiota and early growth. Despite these limitations, this study provides locally relevant evidence from an understudied coastal population and highlights the potential role of *Clostridium* overabundance as a biomarker of growth faltering in early infancy.

Conclusions and Recommendations

In this study of 6-month-old infants from coastal areas of Central Sulawesi, Indonesia, *Clostridium* was the only bacterial genus independently and inversely associated with WAZ, even after controlling for maternal, perinatal, and environmental factors. In contrast, *Bifidobacterium*, *Lactobacillus*, *Bacteroides*, and *E coli* showed no significant associations with WAZ.

These findings indicate that higher *Clostridium* abundance is associated with lower WAZ and highlight the importance of maintaining a balanced gut microbiota for optimal infant nutrition. Future longitudinal studies should further examine how breastfeeding practices, maternal nutrition during pregnancy and lactation, and microbiota-supportive approaches may influence infant gut microbiota composition and growth outcomes in coastal and resource-limited settings.

Acknowledgments

The authors acknowledge the support of the government of Banggai Regency, especially the community health centers in Batui Selatan and Moilong, for their contributions to this research. They also thank the Hasanuddin University Medical Research Center for assistance and expertise in gut microbiota analyses.

Funding

This research did not receive any specific grant from funding agencies in the public, commercial, or not-for-profit sectors. No external funding was received for this study.

Abstract

Background: In Saudi Arabia, unintentional injuries among children represent a prevalent and significant public health issue and severe injuries are of the leading indications for hospitalization and impairments.

Objective: This study aimed to describe the pattern of unintentional trauma in children admitted to Abha Maternal and Children Hospital, South region of Saudi Arabia.

Methods: This study was a prospective descriptive, cross-sectional, hospital-based study, which was conducted in the Pediatric Intensive Care Unit, Maternity and Children's Hospital, Abha, Aseer region, Saudi Arabia. This is the central and main hospital in the region but not the only hospital receiving childhood injuries. The study period was from January 2023 to January 2024. Children's age groups were from 0 to 12 years old. All children in the study were admitted with a diagnosis of unintentional injuries, like RTAs (road traffic accidents), falls, and other home accidents. The study included 104 children and the data collected were analyzed using SPSS (version 27; IBM Corp). Appropriate statistical tests were used for the analysis and all tests were two tailed and probability $P \leq .05$ is considered significant.

Results: The sample size of the study was 104 children. The gender distribution was 35 females (33.7 %) and 69 males (66.3 %). The patients were recruited from 18 cities in the Aseer region. About half of the patients (49%) were aged 6 - 12 years. Road traffic accidents (RTA) represent the highest percentage of accidents, with 66 (63.5%) children, followed by falls from height with 38 (36.5%) patients. The most significant types of injuries were head and brain injuries 37 (35.6%), followed by chest and lung injuries 12 (11.5%). Most patients (n=62, 59.6%) remained admitted to the pediatric intensive care unit (PICU) for one to three days. Followed by three to seven days (27), then eight to 14 days (14). Head/brain axonal injury is also the most common injury associated with complications, followed by polytrauma.

Conclusions: Road traffic accidents are a significant cause of death and disability in Saudi Arabia for all age groups. A strong association existed between the PICU admission duration and the outcome (P=.02). Health and community institutes and governments should increase community education about the risks and consequences of RTA, strengthen traffic rules and laws, and punish violators.

KEYWORDS

pattern; characteristics; unintentional injuries; children; complications

Introduction

Worldwide unintentional injuries contribute enormously to childhood mortality with nearly 1 million deaths per year in children and adolescents below 18 years [1]. Around 12% of the deaths due to injuries occur in children, the most common causative injuries of death in this age group are: road traffic accidents, drowning, burns, falls, and poisonings. Many of these mortalities are preventable [2]. In children and also the injuries largely contribute to child hood morbidity and can lead to severe occupational malfunctioning or non-functioning and/or social and psychological impairment [3]. There may be background

XSL•FO
RenderX

risk in many cases [4]. Unfortunately, there is a paucity of data regarding trauma incidence and prevalence, specifically for Saudi Arabian children [5].

Injuries, especially unintentional injuries, are a leading cause of death among children and adolescents and a severe public health problem worldwide [6,7]. Unintentional injury is a disability that occurs under accidental circumstances [8]. The World Health Organization Report 2002 stated that injuries are the sixth leading cause of morbidity and mortality in childhood [9]. One of the most unintentional injuries in the world is road traffic accidents (RTA), which are the primary cause of unnatural deaths in the world and children, causing a loss of more than 260,000 lives in the 0 - 19-year age group annually [10] and a significant effect on the world's economy [11-13].

Investigations have shown that children and adolescents are most vulnerable to accidents. Due to physiological limitations, the growth process and behavioral characteristics (experience, need to test, explore, adventure, and risky behaviors) provide accident conditions for this group. Along with other environmental factors, for example, parents' low ecological safety levels and children's supervision and care have led to more severe and dangerous forms [14]. Every year, millions of children lose their lives because of preventable accidents. Burning, poisoning, falls, and trauma (accidents) are the four leading causes of mortality in children. Accidents represent 50% of all deaths among children, and one in every six children admitted to a children's hospital emergency department is related to accidents [15]. . Therefore, accidents are one of the leading health problems that continually threaten children's health [16]. This study was conducted due to limited data about the epidemiology of unintentional injuries among Saudi children and adolescents to increase the knowledge about the characteristics of these injuries for further appropriate intervention and to decrease the burden of such terrible events.

The study aimed to determine the pattern and clinical types of the unintentional injuries and trauma in children aged 0 - 12 years admitted to the PICU in Abha, Aseer region in KSA; together with determining of the short-term outcome and utilization need of the health facilities of the hospital including ICU admission and duration of hospital stay in this study group.

Methods

Study Design

This study is a prospective descriptive, review with follow up of children admitted with unintentional trauma since admission to the hospital and use of the pediatric intensive care unit database during the period of the study.

Study Setting

Pediatric Intensive Care Unit, Maternity and Children Hospital, Abha, Aseer region, Saudi Arabia.

Study Population and Sample

The study sample includes 104 of the children admitted with unintentional trauma to the Pediatric Intensive Care Unit, Maternity and Children Hospital (MCH), Abha. Fifteen to twenty pediatric patients were admitted to the pediatric department monthly due to unintentional injury.

Age group: From 0 to 12 years (because MCH receives pediatric patients up to 12 years)

Study period: January 2023–January 2024

Inclusion criteria: Any pediatric patient admitted with a diagnosis of unintentional injury, such as RTA, pedestrians, and falls

Exclusion criteria: Children with burns, poisoning, drowning, foreign bodies, and strangulation were excluded because these cases usually were admitted to other hospitals

Sample size: The formula used for calculation of sample size is:

n = (Z^2 * p * (1-p)) / d^2

Where:

n=sample size

Z=*z* score corresponding to the desired confidence level (eg, 1.96 for 95% CI)

p=expected prevalence or proportion (use 0.5 if unknown)

d=margin of error (eg, 0.05)

Sampling technique: Prospective review of the department database or Logbooks, as well as review of pediatric patients with a diagnosis of trauma

Data Analysis

Data were collected on a research data collection sheet and Data management and analysis were performed using SPSS (version 27.0; IBM Corp). Numerical data were summarized using medians and/or ranges. Categorical data were summarized as numbers and percentages. Estimates of the frequency were done using the numbers and percentages. χ^2 or Fisher tests were used to compare between the independent groups with respect to categorical data, as appropriate. Time to discharge was estimated using the Kaplan and Meier method. It was calculated from date of admission to date of discharge. Differences between the survival curves were assessed with the log-rank test. All tests were two-tailed and $P \leq .05$ is considered significant.

Study Recruitment

This included identifying and sourcing of the study population group according to the criteria of the study.

Ethical Considerations

The study was conducted in accordance with the Declaration of Helsinki and the research committee of Aseer Institutional Review Board, Directorate of Health Affairs, Aseer Region, Ministry of Health, Saudi Arabia, approved the study (REC 8-3-2023 dated 4/3/2023). Informed consent to participate was obtained from families (verbal approval) before being asked about the child. Privacy and confidentiality of the hospital data used was strictly kept and the data used was deidentified.

Results

The current study included 104 pediatric patients. Ninety-nine patients were admitted to the PICU, three to the pediatric surgical ward under PICU team care, and two to the ER. More than two-thirds (n=69, 66.3%) of cases were males. Nearly half of the cases were aged 6 to 12 years (n=51, 49%). Most cases were of Saudi nationality (n=96, 92.3%). The patients were recruited from 18 cities in the Aseer region. Abha (n=53, 51%) and Khamis Mushet (n=17, 16.3%) had the highest percentage of patients, respectively. Most cases (n=99, 95.2%) had no past medical history. In contrast, a small proportion of patients had medical conditions, such as factor VIII deficiencies, global developmental delay, preterm birth with congenital heart disease, or nonspecific conditions. Road traffic accidents (RTA) represent the highest percentage of accidents, with 66 children representing 63.5%, followed by falls from height with 38 patients representing 36.5%, and both are notably more frequent in the 6 - 12 age group. Meanwhile, home accidents accounted for only 3 cases (2.9%) of all accidents. The most used method for transferring patients from the accident site to the nearest hospital was a red-crescent ambulance 47 (45.2%) patients, followed by a family car 46 (44.2%) patients.

More than one-third of patients arrived at MCH 6 - 10 hours after the first presentation 41 (39.4%), and nearly one-third at the first 2 hours 31 (29.8%). More than one-third of cases had head and brain injuries 37 (35.6%), followed by polytrauma (24%). More than half of patients 62 (59.6%) remained admitted to the PICU for [1-3] days, with a median length of stay of about two days, ranging from [1-24] days. Most patients 93 (89.4%) were transferred to the pediatric surgical ward (PSW) from the PICU. Only 6 (5.8%) patients were transferred to another hospital, and 5 (4.8%) patients died in the PICU due to severe injuries, such as multiple fractures and head/brain axonal injury. Most patients (n=89, 85.6%) were discharged from the hospital in improved and stable conditions (Table 1).

Died	5 (4.8)
Length of hospital stay (days), median (range)	2 (1-25)

[a]The percentage of the whole group discharge is taken out of the total number of 104 admitted children; while the percentage of discharge in the subgroups inside the table is taken in relation to the total of the same subgroup (e.g. age group).

[b]Maternity and Children's Hospital.

[c]CT: computed tomography.

[d]PICU: pediatric intensive care unit.

As shown in Table 2, most deaths (n=4/5, 80%) occur among females , and this was statistically significant (*P*=.04). However, there was no statistically significant difference in mortality concerning age, nationality, presence of past medical history, type of trauma, and diagnosis.

XSL•FO
RenderX

Table . Mortality concerning different factors.

Variables	Alive (n=99), n (%)	Died (n=5), n (%)	*P* value
Age groups			.82
Less than 1 year	12 (12.1)	1 (20)	
1 - 5 years	38 (38.4)	2 (40)	
6 - 12 years	49 (49.5)	2 (40)	
Sex			.04
Female	31 (31.3)	4 (80)

Normal CT[b]	8 (8.1)	0 (0)	

[a]Not applicable.

[b]CT: computed tomography.

As shown in Table 3, the median time to discharge from the hospital was 2 days (Figure 1). The type of trauma significantly impacts time to discharge from the hospital. At one week, 34 out of 37 (93%) of patients who fell from a height were discharged, compared to 50 (81%) of patients who had a RTA. This difference was statistically significant (*P*=.41) (Figure 2). One child who sustained a severe RTA with multiple injuries and disability stayed in the hospital for an exceptional period of 25 days. Meanwhile, there was no statistically significant difference in time to discharge with age, gender, nationality, and diagnosis. The details of the injuries sustained by the children in the study group include the following:

1. Head/brain injuries: 37/104 (35.6%) children, of which 22 (21.2%) were associated with different degrees of brain hemorrhage (epidural, subdural , subarachnoid or intraparenchymal); 6 (5.77%) cases of brain injuries were associated with axonal injury, and 2 (1.9%) cases with fracture base of the skull. Skull fractures were found in 27 (26%) of the cases. Of these, 15 were isolated skull fractures without brain insult and most of them were single bone and nondisplaced with 4 (3.8%) depressed fractures and 3 (2.9%) multiple displaced fractures. A total of 8 cases (7.7%) of head trauma in the group show no abnormal computed tomography or magnetic resonance imaging findings
2. Lung injuries: In 12 (11.5%) cases with chest cage/lung trauma, 2 children (1.9%) had lung contusions, 2 (1.9%) had pneumothorax, 2 (1.9%) cases sustained pulmonary hemorrhage and 1 (0.96%) patient had surgical emphysema
3. Intraabdominal soft tissue organ injuries: 3 cases (2.9%) had splenic lacerations, 2 (1.9%) with liver injury and lacerations, 1 case (0.96%) with renal injury, and 1 case (0.96%) with direct arterial vascular injury
4. Multiple or major limb fractures: i5 cases (4.8%) of polytrauma were seen in the group

Discussion

Principal Findings

Unintentional injuries are accidents or mishaps that cause physical harm to a person. These can include falls, traffic accidents, burns, poisonings, drowning, and various other incidents. Over 900,000 deaths are reported annually due to unintentional injuries in the group of children and adolescents below the age of 18 years , representing 10% of all deaths worldwide [17].

The major findings in this study: of the 104 children with unintentional injuries admitted to Pediatric Intensive Care Unit, MCH, Abha, were as follows: A total of 69 (66.3 %) of patients were males, about half of the patients (n=51, 49%) were aged 6 - 12 years. Road traffic accidents (RTA) represent the highest percentage of accidents, with 66 (63.5%) children, followed by falls from height with 38 (36.5%) patients, The most significant types of injuries were head and brain injuries (n=37, 35.6%), followed by chest and lung injuries (n=27, 26.1%). Most patients (n=62, 59.6%) remained admitted to the PICU for one to three days. Followed by three to seven days in 27 patients (26%) then eight to 14 days in 15(14.1%). Head/brain axonal injury is also the most common injury associated with complications, followed by polytrauma. Overall, 89 (85.6%) patients improved and discharged with no sequelae, 10 (9.6%) were transferred to other units or develop disabilities and 5 patients (4.8%) died.

This study included 104 pediatric patients. Males dominated, accounting for 69 (66.3%) of the study population. This percentage is similar to that reported in studies conducted in Saudi Arabia [16,18,19]. Although there is male predominance, the rate of death was significantly higher (*P* value =.043) in females. Four female patients from the 31 admitted to the PICU died. Most patients were 6 - 12 years old, unlike in previous studies in China and the Netherlands, where age groups 1 - 3 predominated [20,21]. .

The commonly admitted age group in Saudi Arabia was 1 - 5 years [18,19]. This variation in our study can be attributed to RTA, the most common cause of unintentional injuries (representing 66.3% of the study population), followed by falls from heights. RTA has a high incidence in Saudi Arabia, with 81 percent of deaths due to road traffic accidents in the Ministry of Health hospitals, and 20% of the hospital beds occupied by traffic accident victims [22]. Falls represented a higher percentage in similar studies where the smaller age group dominated [16,18]. There is variation in the type of injury according to age group, where RTA predominates in the 6 to 12-year age group, while falling is more common in the younger age groups of 1-to 5-year-olds and less than one year. A study conducted in Makkah explained the higher incidence of falling as a cause of unintentional injuries in their research because of the predominance of the younger age group from one to five years. It attributed this to this age group's curious nature and immature judgment [18]. Another study stated that the incidence of falling decreases with increasing age [23]. The mechanism

XSL•FO
RenderX

of injury can differ in different societies. Foreign body aspiration and suffocation were the most common admission causes leading to death in China, where RTA came in third place [17,20]. The incidence and type of unintentional trauma can be attributed to environmental factors, parental neglect, or maltreatment [17,24]. The most used method for transferring patients from the accident site to the nearest hospital was a red-crescent ambulance 47 (45.2%), followed by a family car 46 (44.2%). More than one-third of patients arrived at MCH 6 - 10 hours after the first presentation 41 (39.4%), and nearly one-third at the first 2 hours 31 (29.8%). Eighty-nine of patients (85.6%)were discharged from the hospital in an improved and stable condition. The mortality rate among the patients was comparatively low 5 patients (4.8%). This suggests that although some individuals exhibited injuries that were too grave to survive, the mortality rate remained regulated, possibly indicative of adequate medical care in most cases. The outcome was also good in other studies in Saudi Arabia, where the majority improved; however, the percentage of discharge with complications and disabilities was higher in different studies [18,19]. . The incidence of death was higher in patients with a longer duration of admission to the PICU. A strong association existed between the PICU admission duration and the outcome (P=.023).

The most significant types of injuries were head and brain injuries 37 (35.6 %), followed by polytrauma 22 (21.2%). Head and brain injuries and polytrauma carry a higher percentage of disabilities, complications, longer duration of admission, and death than other diagnoses. This result agrees with similar studies in Saudi Arabia [16,18] Similar results were also found in other countries [24].

Road traffic accidents are a significant cause of death and disability in Saudi Arabia for all age groups. Health and community institutes and governments should increase community education about the risks and consequences of RTA, strengthen traffic rules and laws, and punish violators. Expanding road safety measures to prevent head injuries is also important.

Limitations of Discussion

For more generalizations of the results and implications of this study; further elaboration of the problem on a wider basis is needed for this area of KSA to include all the hospitals in the region of Aseer

Conclusion and Implications

Many cases of the unintentional trauma in children in Aseer region in KSA are preventable by using measures to raise the population safety of the RTA as they represent a major type of injury in this region and also safety measures for decreasing the incidence of fall especially the area is a high altitude area in KSA.

Abstract

Background: Digital health programs are increasingly important in the treatment and prevention of mental health problems in young children. However, suboptimal family engagement with a program may hamper its effectiveness. Family engagement in digital mental health programs is multifaceted and poorly understood, with ill-defined relationships among aspects of participation and program outcomes (ie, what constitutes *effective* engagement). Moreover, little is known about the barriers and facilitators to effectively engaging families at risk for anxiety, who may not be actively seeking treatment.

Objective: *Making Mistakes* is a novel, internet-based, cognitive behavioral preventive program for caregivers and their 5- to 7-year-old children, which aims to reduce the risk of anxiety by targeting family transmission of perfectionism or error sensitivity—that is, negative overreactivity to mistakes. This mixed methods study examined multiple facets of parent-and-child engagement in *Making Mistakes*, including adherence, cognitive and affective engagement, barriers, facilitators, and perceived outcomes associated with involvement.

Methods: A total of 87 dyads were included in a quantitative analysis of adherence to the program, including overall adherence and sustained engagement. Eighteen dyads completed qualitative interviews, which were subjected to a qualitative thematic analysis. Finally, a sample of *Making Mistakes* activity journals was qualitatively reviewed and synthesized.

Results: Parent and child adherence were strongly positively correlated (r_{85}=0.95). Dyads had low adherence to the weekly modules, which did not differ by intervention condition. Completion rates averaged 20%, with adherence declining over time. In contrast, qualitative data indicated high levels of investment in program content and topics, elucidated barriers and facilitators to program engagement, and highlighted numerous psychosocial benefits.

Conclusions: Engagement, operationalized as rote adherence to an intervention developer's criteria, may insufficiently capture the aspects of participation that are most meaningfully related to positive outcomes. Researchers and intervention developers should prioritize cognitive and affective aspects of engagement with program content, along with promoting and assessing behavioral engagement beyond adherence to program components. *Making Mistakes* shows promise as a low-cost, disseminable strategy to reduce intergenerational risk for anxiety. These findings have particular relevance for digital health programs focused on prevention, parent-child dyads, and anxiety and perfectionism.

Introduction

Engagement With Digital Health Programs

Despite the potential of digital health programs (DHPs) to prevent and treat mental health conditions in young children, DHPs have yet to make a significant mental health impact at scale. Many DHPs have faced suboptimal engagement [1], which also tends to decrease over time (ie, "the law of attrition") [2]. Engagement in DHPs is multifaceted, encompassing affective (eg, enjoyment), cognitive (eg, attention), and behavioral (eg, adherence to intervention prompts) components

XSL•FO
RenderX

[3]. Moreover, interaction with a DHP's user interface is distinct from the enactment of the DHP's specific behavior change techniques, which is further distinguished from engagement in relevant health behavior changes [4]. Importantly, *effective* engagement is defined as the quantity and timing of energy investment into a stimulus or task that is required to bring about a desired outcome [3]. Understanding effective engagement across multiple dimensions is important to DHP development, dissemination, and evaluation.

Typical patterns of participation vary widely across DHPs, consumers, target conditions, and settings, and depend on how engagement is operationalized [5]. Thus, rather than assuming a rigid, "one-size-fits-all" approach, authors have called for research that focuses on the degree of improvement as a primary metric of engagement success while also exploring multifaceted patterns of involvement [5,6]. Meta-analytic work has shown that engagement in a DHP for mental health is positively associated with clinical improvement, regardless of the intervention focus or whether the intervention is guided or unguided [7]. In one anxiety-focused DHP, the *Unwinding Anxiety* mobile app, completing a higher proportion of modules, as well as specific behavior change techniques, was associated with greater improvements in mental health symptoms [8]. Few preventive, parent-mediated digital interventions for youth 7 years or younger have been rigorously evaluated [9]. Moreover, typical patterns of participation in these programs remain unstudied. Inclusion of consumer perspectives in intervention design, development, and dissemination may help to overcome challenges with program engagement, thereby enhancing outcomes [10]. Understanding consumer engagement in digital mental health interventions is critical, particularly for programs focused on young children.

In parent-mediated interventions, caregiver participation engagement (CPE) refers to active participation in a program, including follow-through with homework and behavior change plans [11]. A meta-analysis found that CPE in youth-focused prevention programs was associated with increases in positive parenting behaviors and decreases in child internalizing and externalizing symptoms [11]. Given that family engagement in mental health intervention programs continues to be a challenge [12], especially in prevention programs [13,14], and that the determinants of CPE are understudied [11], more attention is needed to identify the barriers and facilitators to effective involvement in family-focused behavioral health interventions.

Families With Elevated Error Sensitivity

In search of empirically informed targets for the prevention of anxiety, over 50 studies to date have linked higher error-related brain activity with anxiety, in both adult and pediatric samples [15-17]. This neural marker, the error-related negativity (ERN), is generated when mistakes are made on a task and can be recorded using an electroencephalogram. A larger ERN in children is related to higher anxiety. Furthermore, an elevated ERN in early childhood independently predicts the risk for clinical anxiety in later childhood [18]. The ERN has been associated with *error sensitivity*, or the tendency to react negatively to one's own mistakes [19]. Concern over making mistakes is also a hallmark of maladaptive perfectionism [20]. Given these findings, our research team developed an intervention that aims to impact the ERN by targeting overly negative responses to making mistakes (ie, behavioral error sensitivity or perfectionism) in young children [21].

Families high in error sensitivity or perfectionism may face unique challenges in engaging with preventive DHPs. Perfectionistic families may not always seek psychological services; thus, understanding engagement in non–treatment-seeking perfectionistic families is important, consistent with a *prevention* or health-promotion perspective [22]. According to the social expectations model, parents with unreasonably high expectations for their children may have an overcontrolling parenting style, thereby increasing the risk of maladaptive child perfectionism [23]. Moreover, the social learning model (also [23]) suggests that parents pass on perfectionistic behaviors to their children via modeling. These hypotheses are supported by meta-analytic research, which has revealed that parental self-oriented perfectionism, expectations, and criticism positively relate to child perfectionism [24]. Maladaptive perfectionism may result from child traits that dynamically interact with parental factors, such as harsh or critical communication, authoritarian or controlling parenting, psychological control, perfectionistic modeling, and excessive performance feedback focusing on error avoidance [25-31]. Furthermore, behavioral genetics has shown that perfectionism is moderately heritable, meaning perfectionistic families likely share genetic diatheses [20].

Few interventions have targeted perfectionism in youth [32,33] (see [34] for a cursory review). Parent-mediated interventions for perfectionism should target theorized intergenerational mechanisms of children's maladaptive perfectionism, such as setting excessively high standards, encouraging avoidance of mistakes, and modeling perfectionism [23,24,35]. Published recommendations on preventive interventions for perfectionism include adopting a positive psychology focus; providing a rationale and discussing risk; targeting maladaptive perfectionistic beliefs; providing cognitive reappraisal strategies; promoting a growth mindset, self-acceptance, and self-compassion; and engaging parents in reducing criticism, modeling calm responses to errors, and reiterating anti-perfectionistic messages [36].

Current Digital Health Intervention Program

In accordance with empirical findings, theory, and guidelines, a preventive DHP targeting error sensitivity in 5 - to 7-year-old child-parent dyads has shown pilot efficacy [21]. A randomized controlled trial (RCT) of an expanded version of this program is underway.

Mixed methods approaches can elucidate engagement and implementation outcomes in parent-mediated digital interventions (eg, [37-43]). However, little is known about program participation in error-sensitive families. Likewise, there is limited research on family engagement in preventive interventions for anxiety or on DHPs with children under the age of 7 years. Given the increasing importance of DHPs in preventing and treating pediatric mental illness, it is critical to understand *how* families participate in and benefit from these programs, the factors that facilitate participation, and the facets

XSL•FO
RenderX

of involvement that contribute most to program success (ie, *effective* engagement). The findings will enhance the potential effectiveness and reach of DHPs by advancing knowledge of typical family participation in preventive DHPs, clarifying the relationship between engagement and program outcomes, and contributing to a deeper understanding of the factors that influence program participation.

In this study, we examine family participation in a preventive DHP targeting error sensitivity in young children and their parents. We delineate patterns of engagement with *Making Mistakes*, including adherence within dyads; perceptions of program outcomes; and cognitive, affective, and behavioral facets of engagement. We also explore facilitators and barriers to family involvement. The research questions are as follows: (1) To what degree do dyads engage in *Making Mistakes* with fidelity, including program adherence and enactment of content learned? (2) How is participation perceived to impact family functioning? (3) What are facilitators and barriers to family engagement? (4) How do qualitative descriptions of engagement contextualize quantitative findings? This study builds on the emerging body of parent-mediated and digital mental health interventions by using mixed methods to explore families' patterns of program participation. We incorporate robust qualitative methods to contextualize quantitative findings on program adherence and gain an in-depth understanding of participation. Understanding barriers and facilitators to engagement—and what constitutes *effective* engagement—may improve mental health outcomes for families by augmenting the impact of *Making Mistakes* and similar programs.

Methods

Recruitment and Participants

This mixed methods study included families who were randomized to the 3 active treatment arms of an ongoing RCT evaluating *Making Mistakes*, a web-based program targeting anxiety risk in 5‐ to 7-year-old children. Parent-child dyads were recruited from a community, nonclinical sample. In the larger study, dyads were interviewed about their experience, including program acceptability and appropriateness. Procedures and methods for the RCT can be found elsewhere ([34]; also see Multimedia Appendix 1).

Parent-child dyads were recruited for quantitative assessment as part of their participation in the larger RCT. Inclusion criteria were as follows: (1) elevated error sensitivity as measured by elevated scores on the Child Error Sensitivity Index, Child Error Sensitivity Index–Parent Report, or the Parent Sensitivity to Child Errors Index [19] and (2) completion of the baseline intervention module. Two dyads were excluded because they did not receive the weekly text message or email reminders as prescribed, due to clerical errors. An additional 7 dyads were excluded for not completing the entirety of the baseline intervention module, resulting in a final sample of 87 dyads for the quantitative assessment (n=30 with both parent *and* child in the active condition [P+/C+], 30 parent-active+child-control [P+/C–], and 27 child-active+parent-control [P–/C+]). Reported reasons for not completing the baseline module indicated barriers related to childcare requirements (ie, siblings), busy schedules, and factors potentially related to child age or developmental level (eg, child refusal to continue the study).

Families were eligible for qualitative interviews if they were randomized into 1 of 3 active intervention arms and completed at least a portion of the baseline module. The lead author (IAM) conducted all interviews, which were solicited across various phases of intervention completion. Random and convenience sampling were used for the first 10 interviewees. Strategic sampling was used for the remainder, which prioritized P+/C+ dyads. Sampling aimed to match or surpass the demographic diversity of the overall participant sample with respect to the timing of the interview vis-à-vis the phase of the study or intervention, race or ethnicity, gender and sexual orientation, and relationship status. Recruitment goals were based on data saturation, which often occurs between 10 and 17 interviews [44]. Data saturation was reached at 18 dyads (n=18 adults, 14 children). Additional information regarding qualitative data collection is reported elsewhere [45].

Ethical Considerations

Study procedures were approved by Florida State University's Institutional Review Board (STUDY00000605). Informed consent was obtained from parents, and assent was obtained from children. Participant information was kept private and confidential. We compensated participants with a US $25 gift card.

Study Design and Procedure

Overview

We used a qualitative-dominant, convergent mixed methods design [10,46] to elucidate family engagement in a preventive DHP targeting error sensitivity. The convergent design—wherein qualitative and quantitative data were collected during the same phase of the research process, analyzed separately, and integrated during interpretation—allowed us to gain a deeper understanding of effective family engagement. As a complement to the RCT's ongoing efficacy evaluation, this study focused on process-oriented features, implementation characteristics, and multidimensional indices of engagement [10]. The first author conducted the semistructured interviews both virtually and face-to-face in the lab setting. Interviews lasted, on average, 48 minutes and were audio-recorded and transcribed.

Intervention

Making Mistakes (described elsewhere in greater detail) [34] includes independently delivered child and parent modules. Child content included cognitive tools (eg, "mistakes are how we learn"; "mistakes can be funny"), listening to your "mistake buddy," and standing up to your "mistake bully," as well as behavioral components such as making mistakes on purpose (exposure) and challenging oneself to try hard things. Parent or caregiver modules similarly focused on exposure, encouraging "challenge-zone" child behavior, emphasizing effort over outcome, providing psychoeducation about error sensitivity, modeling positive reactions to mistakes, and responding positively to child mistakes. Furthermore, parent modules also included general positive parenting tools, such as the use of

XSL•FO
RenderX

positive attention and one-on-one, child-led play (special time). Parents and children, respectively, completed the core intervention: a 45-minute baseline module, which was followed by 6 months of less than 5-minute video lessons, thrice monthly. Paper journal activities corresponded with the weekly content, and parents received weekly text and email reminders with links to access modules accompanied by brief messages to reinforce program content (eg, "You can encourage your child to do something challenging, even if they might make mistakes!"). Links were specific to each weekly video, and parents received 2 separate links (one for weekly parent content and one for child content). Participants "logged in" to each respective module by entering their study ID#, which was used to estimate rates of adherence. Thus, if both the parent and child content were accessed for a respective week, 2 separate ID "logins" were recorded.

Measures

Quantitative Measures: Adherence

Adherence was estimated via metadata extracted from the study website, which logged whether each respective module was accessed at any time between baseline and the 6-month follow-up assessment. If a particular module was associated with 2 or more logins for the same participant, only the first login was counted. As both conditions were housed on the same website, rates of condition contamination for the weekly modules were moderate; 1 active-condition parent (P+) accessed a control module, 2 P– parents accessed an active module, and 1 C– child accessed an active module. Given that all these participants had completed the correct initial (primary) module, they were included in the analyses. A summative measure of adherence was computed for parents and children, respectively, and the proportions of module adherence were calculated by dividing the total number of modules completed by 18. Parent and child adherence were then averaged to create a single adherence score. Finally, for sensitivity analyses, a composite variable was created for each of the 18 modules: whether any member of the dyad (including parent, child, or both) had logged into the respective module.

To characterize *sustained adherence*, a more sensitive metric of engagement, an additional variable was computed for parents and children, respectively: the number of *unique weeks* a participant logged in. Parent and child sustained adherence were averaged into a single score.

Qualitative Measures: Semistructured Interviews and Journal Entries

An interview guide [34] was developed for this study based on similar guides (eg, [40]). Interviews adhered to existing guidelines on semistructured interview research, including the use of fieldnotes and the incorporation of author positionality [47-50]. To further characterize patterns of CPE and child participation, a sample of paper journal entries was qualitatively reviewed. These included 32 journals photocopied following the baseline module (n=16) or returned at post treatment (n=16), including child (n=16) and parent journals (n=16). Patterns of engagement were reviewed holistically by the lead author (IAM), with a focus on the degree of completion, thoroughness and coherence of responses, common themes, and behavioral commitment language. The findings were integrated with qualitative and quantitative findings on engagement and fidelity.

Data Analyses

Adherence was reported descriptively for children and adults, including rates of overall and sustained adherence. A Welch's ANOVA examined differences in adherence by intervention condition. To interpret the qualitative data, a standard thematic analysis informed by the framework method was performed [51,52] using the NVivo software (version 12.7.0; by Lumivero). This study relied on a codebook generated for a prior study, and data preprocessing is described elsewhere in further detail [45]. Summarily, the analysis used a thematic framework [53], data familiarization, iterative development of a coding scheme and coding, double-coding and coauthor consensus building, recoding, development of a thematic matrix, and interpretation of data via the themes. The thematic matrix was developed using a combination of deductive and inductive processes. Rigor and trustworthiness were established through the use of previously published inquiry methods, strategic sampling methods to achieve a diversity of perspectives, triangulation of multiple data types, consultation, integration of author positionality, negative case analysis, and member checking [47,54].

Results

Overview

Our quantitative and qualitative results provided complementary insights. Although quantitative patterns revealed relatively low fidelity of adherence, this did not translate to poor engagement with the content. Importantly, barriers to high-fidelity participation were not always barriers to overall program success. Qualitative results highlighted diverse and idiosyncratic barriers and facilitators to engagement and suggested numerous positive outcomes of the program that, in turn, facilitated engagement.

Quantitative Findings

Demographics are summarized in Table 1; additional demographics of the qualitative sample are reported in Table S1 in Multimedia Appendix 1. Parent and child overall adherence were strongly positively correlated (r_{85}=0.946, 95% CI 0.919-0.965; P<.001). The overall rate of adherence to the weekly modules was approximately 20%, with substantial variability; indeed, 43.7% (n=38) of the parents and 44.8% (n=39) of the children did not log into any of the weekly modules. Parent and child sustained adherence were also strongly positively correlated (r_{85}=0.949, P<.001, 95% CI 0.923-0.966). Table 2 shows adherence by parent and child (see Table S2 in Multimedia Appendix 1 for analogous data within the qualitative sample). Furthermore, adherence declined over time (Figure 1).

[a]n=83 for relationship status and parent age ($n_{missing}$=4). Full sample: mean parent age 36.6 (SD 6.0; range 22-52) years; mean child age 6.2 (SD 0.8; range 5-8) years. Interview sample: mean parent age 36.4 (SD 6.3; range 25-48); mean child age 6.2 (SD 0.9; range 5-8).

Table . Overall adherence rates and sustained adherence to the weekly modules (n=87 dyads)[a].

Dyad member	Number of unique weeks		Number of total modules		Percentage of total modules	
	Mean (SD)	Median (IQR)	Mean (SD)	Median (IQR)	Mean (SD)	Median (IQR)
Parent	2.3 (3.7)	1 (0-2)	3.4 (5.2)	1 (0-4)	19 (29)	6 (0-22)
Child	2.2 (3.5)	1 (0-3)	3.8 (5.6)	1 (0-6)	21 (31)	6 (0-33)
Average	2.3 (3.5)	0.5 (0-2.5)	3.6 (5.3)	1 (0-6)	20 (30)	6 (0-33)

[a]Modules were delivered 3 out of 4 weeks, with assessments given every fourth week. Adherence ranged from 0 to 18 for number of modules completed (both parent and child); for unique weeks, it ranged from 0 to 14 (child) and 0 to 15 (parent).

Figure 1. Rates of parent and child adherence by weekly module. "Weekly module" refers to completion of the respective module at any time from baseline to 6-month follow-up.

ANOVA assumptions were not met (skewness=1.98; kurtosis=3.15; nonhomogeneity of variance). Thus, a Welch ANOVA, with Games-Howell post hoc comparisons, was used to test for differences in average sustained adherence (ie, number of unique active weeks) by intervention condition (P+/C+: mean 2.37, SD 3.48; P+/C–: mean 2.77, SD 4.26; P–/C+: mean 1.56, SD 2.54). The test was not significant ($F_{2,54.84}$=1.05, ω^2_random=−0.002, 95% CI −0.012 to 0.038; *P*=.36), indicating no differences in sustained adherence rates by condition. Post hoc comparisons revealed that sustained adherence in P+/C– was not significantly greater than in *P*+C+ (95% CI −2.02 to 2.82; *P*=.92, or P–/C+, 95% CI −1.01 to 3.43; *P*=.39); nor was there a difference between P–/C+ and *P*+C+ (95% CI −2.74 to 1.12; *P*=.57). (As a sensitivity analysis, we fit a population-averaged logistic model using generalized estimating equations with exchangeable working correlation to account for within-dyad dependence across weeks. The Condition × Week interaction was not significant (Wald χ^2_2=4.36; *P*=.11), indicating that completion trajectories across modules did not differ by condition. This result converged with the primary Welch ANOVA findings.)

Qualitative Themes

Overview

Table 3 shows a summary of qualitative themes and subthemes with example quotes. The themes titled (1) diverse family characteristics and needs and (2) program benefits are described in greater detail below. Patterns of journal completion revealed meaningful parental participation in the baseline intervention module. Journal review revealed detailed, specific written responses indicating deep cognitive and affective engagement with the content, as well as concrete behavioral intentions. A review of completed child journals indicated that some journal activities (eg, intentional misspelling tasks) were inappropriate for some younger children and that adult assistance facilitated journal completion. In addition, children's journal entries

XSL•FO
RenderX

showed a mix of internally consistent responses (eg, endorsed positive self-talk such as "Everyone makes mistakes!" and did *not* endorse "trouble making mistakes"; ie, error sensitivity) and inconsistent responses (eg, circling *all* response options available, even when conflicting).

Table . Qualitative themes and subthemes with example quotes[a].

Theme and subtheme	Example quote
Diverse family characteristics and needs	
Broad applicability	"… she kind of fell into all the categories … being shy, being critical of herself … and like what other people thought, um, that fit her like a tee. Um, she has big feelings, deep feelings and... it resonated." (Parent 15)
Life circumstances and family structure	"I really have a desire to model trying new things, and putting myself out there, like being vulnerable to maybe not being great at first and, you know, working to get better … It's just so hard with kids and … I have four kids, [aged] seven and under." (Parent 4)
Program benefits	
Mindful parenting	"I'm, like, trying to be more mindful of it … Because I normally would overreact ... I feel like, 'Oh, my God, I'm such— like, 'I can't believe I did that'. (Parent 9)"
Ripple effects	"I tried to change the way I do things, which, honestly, it positively affects her … she's a lot more open, willing to talk and, um, you know, she doesn't get as … upset or anything, or have breakdowns and all." (Parent 6)
Improved parent-child relationship	"We have completely changed up everything [we do] in the house… If she did something wrong, we would say … 'is that a good choice?'… 'what are some better choices?' … 'because if you do this, this is what happens'... So now it's completely different … We redirect, and we talk about it and … actually figure—solve the problem." (Parent 6)

[a]Eighteen individual interviews were conducted with parent-child dyads, which were coded and subjected to a thematic analysis.

Diverse Family Characteristics and Needs

Overview

Families reported diverse barriers and facilitators to engagement. However, interviewees felt that *Making Mistakes* was broadly appropriate for their family and could offer at least *something* to other families. "I think it definitely should be a thing that, that's like, done by every parent" (Parent 12). Some respondents expressed that the program might be most useful for families of children with behavioral or emotional challenges, or overwhelmed parents in need of encouragement.

Facilitators and barriers to participation emerged with respect to both parent and child traits. Parental facilitators included a willingness to troubleshoot difficulties, along with perseverance in practicing strategies learned, even in the face of perceived failures or setbacks. Individual child differences also served as facilitators and barriers, such as attention span or ability to sit still, rambunctiousness, and tolerance of uncertainty. "My daughter is a planner. She doesn't like surprises … She's not great with … change … or transitions, so I kind of have to talk her through … her plan for the day" (Parent 15).

Broad Applicability

Children varied in their error sensitivity and other challenges. Some parents described moderate child error sensitivity, with bouts of low frustration tolerance. Others' children tended to actively approach challenges and had low error sensitivity. Still others described more significant behavioral or emotional challenges or expressed that their child perfectly fit the program's description of being highly error-sensitive (eg, shy, perfectionistic, avoids challenging tasks, or easily discouraged). Some parents felt their young children had not yet developed the "bad habits" of responding poorly to their own errors. Indeed, *Making Mistakes* content was suggested in some cases to be even more relevant to other children, including older siblings or others outside the home.

> *I also try to be mindful of it with my students … My niece and nephew, I'm like, "They need this …" He is going to be the type of kid that's at MIT, and he's gonna be like, real stressed out … and ready to like, [jump] off a bridge if something happens.* [Parent 9]

Interestingly, parents also varied in their own error sensitivity. Some communicated a desire to break cycles of "intergenerational trauma"—or maladaptive cognitions and behavior. Furthermore, some identified immense difficulty resisting the urge to correct their child's mistakes, with some equating mistakes with *failure*.

> *I used to not treat [mistakes] correctly … I am [no longer] … pushing him to, to do all the things perfect[ly], I think, you know mainly [Making Mistakes] was for me (chuckles)…* [Parent 18]

> *… the way I've been raised, is like, always, like push, and, you know, achieve, and kind of compared [myself to others] a lot too. So, mistakes are kind of … not looked upon well … I do just see a value in [the weekly activities], umm, for me personally.* [Parent 3]

Commonly, parents desired to engage their spouse or coparent in the content. "[My spouse is] a Veteran so … for him, it's

XSL•FO
RenderX

separating that mindset of 'okay, this is not soldiers, this is a child'… he's still working on that … because he's very much sometimes in that military mindset" (Parent 6). Facilitators of parent and spousal or coparent participation emerged, including elevated parental error sensitivity, interest in learning about child development, a growth mindset, and favorable views of science; some postulated that younger and more "progressive" parents would find the intervention compelling. Despite heterogeneity in families' perceived problems, challenges, and circumstances, interviewees resoundingly felt *Making Mistakes* was applicable in some way.

Life Circumstances and Family Structure

Engagement was influenced by circumstances including family composition, busyness, employment status, and unpredictable or temporary stressors. However, no simple pattern of participation emerged; indeed, some with minimal circumstantial barriers engaged with low fidelity, and others with myriad external barriers were highly motivated to engage. Thus, engagement was dynamic, complex, and influenced by multiple factors. Specific barriers included single parenthood, excessive childcare demands (especially having multiple young children), busy family schedules, and a desire to avoid overfilling their child's plate. Busyness decreased adherence to the program.

Temporary circumstances dynamically impacted interest or ability to engage in *Making Mistakes*, including moving or job loss (barriers); resolution of a problem such as bullying, leading to a reduction in child psychosocial problems (decreased motivation to engage); or having an infant child, which led to higher perceived program relevance yet more barriers to actual participation. Overall, family or household structure, employment, and busyness were viewed as barriers, with short-term stressors (eg, moving, newborn care, child bullying) also contributing to the ability and motivation to participate. However, life circumstances, along with perceived child problems, only explained a portion of the variation in program engagement.

Program Benefits

Overview

Dyads consistently expressed that their family had benefited in some way from *Making Mistakes*, which, in turn, facilitated participation fidelity. Cognitive and behavioral change came from the repeated implementation of strategies including reframing mistakes, modeling positive reactions, and responding positively to children's mistakes. Parents described positive changes in the intervention targets (ie, child error sensitivity) as well as in their own error sensitivity, parent-child communication, and family emotional health. Cognitive changes (eg, increased awareness, modified beliefs about mistakes) were framed as leading to behavioral changes in parents and their children, as well as in other family members or individuals outside of the family. Interviewees also evidenced internalization of program concepts and strategies. For example, some parents struggled to recall specific program-related changes until the strategies were cued, after which they expressed strongly positive feelings toward the content.

> *[This program] put a name to [encouraging her to do hard things] and kind of highlighted and reminded me … to suggest those things and … explain that to her … I do remember thinking about those things, and being like, "that is extremely good information …" [Special time] is something I was not doing before, um, and then I kind of forgot that … this program was the one that kind of like, turned that light on.* [Parent 4]

Children struggled to identify changes; however, some described internalized cognitive strategies, such as listening to their "mistake buddy," often with helpful scripts. For some, perceived benefits included reduced performance anxiety and perfectionism, increased positive goal-setting and bravery, and improved attentiveness and self-regulation abilities.

> *Before, I tried not to make mistakes that mu- a lot, which I, which I did. And now it's, and now I know that it's okay to make mistakes. So, so, it's just fine for me… I messed up and I was like, "it's okay!".* [Child 12]

Mindful Parenting

Interviewees gained increased awareness of their impact on their children through a combination of psychoeducation on error sensitivity and being urged to pay more attention to their own behavior and their child's psyche.

> *I wondered why my son gets so angry. And ... [now I understand he gets angry when] he make[s] a mistake, or [when I punish him], stuff like that* [Parent 14]

Parents also gained an understanding of their children's developmental level, as well as naturalistic opportunities to reinforce healthy concepts.

Mindfulness also facilitated resisting the urge to correct or preempt children's mistakes. This reduction in "autopilot parenting" seemed to stem from increased awareness of parents' own behavior, improved frustration tolerance, and tolerance for child messiness. "I would say I've learned to be a little bit more patienter [sic]" (Parent 10). Mindfulness also led to more developmentally appropriate expectations of their children, which deemphasized perfection and outcomes, instead emphasizing effort and the "big picture." Respondents learned to pause before responding, when they would recall program concepts and respond accordingly. Interestingly, parents also highlighted a behavioral outcome not explicitly taught: correcting their own negative responses to mistakes.

> *I'll tell … all my kids like, "Mommy made a mistake," or "Mommy behaved really poorly. I was, uh, I was upset and I, I said a bad word and that was not nice …" Them knowing that I'm not perfect … it gives them the opportunity to not be perfect, too.* [Parent 4]

Ripple Effects

Indirect effects included reciprocal positive influences between child and parent behavior, changes in parents' own error sensitivity, and reported benefits to siblings or family members. "I think she did definitely gain some self-confidence, um, for

XSL•FO
RenderX

sure ... she does really well with the, with the positive reinforcement and praise and … one-on-one time …" (Parent 17). For some dyads, positive family changes were spurred by the child. For instance, parents intentionally reinforced children's *Making Mistakes* content, and some children reminded their parents and siblings to respond positively to mistakes. In addition, a family noted that their child's increased emotional vocabulary facilitated their ability to support him appropriately.

Parents learned to be kinder to themselves, which stemmed from modeling positive reactions to their own mistakes and from frequent, small reminders. "It kind of helped me to get my patience back in line and it, you know, kind of let me realize too, that, 'okay, you're Mommy, but you're not perfect; you're gonna make mistakes, too'" (Parent 10). Positive changes extended to other children and caregivers, as well. Indeed, *Making Mistakes* provided a rationale for parents to encourage coparents to be more mistake-friendly. Most interestingly, program content spread beyond dyads' immediate family, including the workplace, schools, extended family, and friends.

> *I would say something that's like, "Oh my God, I'm such an idiot, I left this out overnight." And she's like, "No, Mom, no negative self-talk" … I'll say something like, "Do you know what this is?" … she'll be like, "An overreaction?" … I think she even told my mom, like, "That's the mistake bully" (laughing).* [Parent 9]

> *… her brother, um, who is autistic and does not cope well with failure, and doing poorly, and making mistakes … she immediately took those ideas home, and does not just say them when she makes mistakes, she's helping to express them to him as well.* [Parent 16]

Improved Parent-Child Relationship

Interviewees also described improved parent-child functioning. This included more positive communication and quality time, more openness, and fewer negative disciplinary methods, as well as explanations provided to children in slower and simpler language, leading to reduced conflict and frustration. Parents replaced harsh and less effective discipline, such as spanking or yelling, with more effective and gentler methods, such as talking things through and using positive reinforcement.

> *We really [reduced his punishments], because in the past we used to say, "you are not going to play with … your Legos," or "you're not going to watch TV, you're not to go to the park." And, now we're being more relaxed with, with him [and only removing video-game privileges] … because it was [too much punishment] for him.* [Parent 18]

These changes led to children more openly discussing their mistakes with parents. "[She's more open about] how she feels… there not being like this fear cloud that, you know, (chuckles) 'Mom's gonna get upset', or 'Mom's gonna shut down'…" (Parent 6).

Families described myriad benefits from their participation. Improvements were noted as receiving helpful tips, which led to more aware and intentional parenting, in turn leading to improved child behavioral and emotional functioning. While respondents generally felt *Making Mistakes* positively impacted their lives, some families described more profound positive results that dramatically improved family functioning and child emotional health.

Discussion

Principal Findings

This study examined participation fidelity, family involvement, perceived outcomes, and barriers and facilitators to engagement in a web-based anxiety prevention program in parent-child dyads. Qualitative and quantitative data showed high levels of engagement in the initial module, albeit low levels of DHP adherence over the 6-month intervention period. Barriers and facilitators included competing demands and program credibility, respectively. Perceived benefits emerged as a key facilitator, resulting from engagement spanning cognitive, affective, and behavioral domains.

Engagement Barriers and Facilitators

Participants completed, on average, one-fifth of the weekly modules, with engagement dropping off over time; however, the modal dyad completed zero weekly modules. Online video and paper journal completion generally coincided, though more families completed the videos, and a few completed journals without the videos. In contrast to the weekly modules, in-lab engagement in the baseline module activities was high. Differences in lab versus home participation align with research demonstrating the utility of human facilitation in promoting DHP usage [55]. DHPs often face low adherence, which may limit therapeutic benefits [56]. Additional work should clarify the relative importance of—and strategies to optimize—different levels of digital engagement, including mechanical program usage, cognitive engagement with program notifications, and behavioral enactment of nondigital tasks resulting from the program [3]. Our findings suggest that this type of DHP may have a strong impact when integrated with human facilitators at the outset, followed by software-delivered engagement strategies tailored to the individual family's needs. Future research should determine the optimal forms of involvement needed to attain program benefits [57].

Numerous barriers and facilitators to family engagement were identified. Facilitators included programmatic factors, such as teaching specific content and strategies, rationale provision (ie, psychoeducation on error sensitivity), mobile-friendliness and navigability, regular reminders with repeated exposure to the content, participation in the in-lab baseline module, and approaching *Making Mistakes* as a shared family activity. Facilitators also included family characteristics, such as child enthusiasm for learning; perceived relevance to child *or* parent based on program descriptions of traits associated with error sensitivity (eg, shy, sensitive, socially anxious, reactive); belief in the program's potential and interest in child psychology and parenting improvement; personal negative experiences with high error sensitivity; and buy-in from co-caregivers. Indeed, the broad applicability of *Making Mistakes* appeared to be a key driver of parent participants' affective engagement, or

XSL•FO
RenderX

emotional investment, with the program, which facilitated behavioral change. Moreover, early improvements in family functioning facilitated buy-in and continued engagement. Facilitators overlapped with those found in previous research, including perceived need, appealing content and delivery, openness to prevention and health promotion approaches, individual motivation and interest, and increased insight into health [38,58]. Our findings on facilitators and barriers shed light on potentially important factors influencing CPE within a DHP [11]. Additional strategies, such as personalization and gamification, may enhance overall program adherence and efficacy.

Both program-related and family-related barriers were identified. Regarding program-specific barriers, some families cited issues related to poor customizability of content and delivery, too many steps to access the content, repetitive or overly simple content, intervention dose (ie, weekly) perceived as daunting, and insufficient incentives to complete the weekly activities. Family-level barriers consisted of low perceived relevance due to parent or child traits; multiple competing demands, especially work and childcare; single-parent status; and temporary stressors, such as moving, separation, or child psychosocial stressors. Barriers overlapped with those found in previous research (eg, [38,42]), including childcare demands, employment, low perceived need, difficulty with program navigability, and perceived burdensomeness. Many barriers were potentially related to social determinants of health and the limited sophistication of the program; therefore, just-in-time adaptive interventions could be developed to equitably address error sensitivity in at-risk families [59]. Of note, the sample only included study completers or partial completers, and thus barriers to initial participation were not captured (eg, see [60]). Overall, barriers and facilitators aligned with those predicted by the health belief model and the theory of planned behavior—such as perceived costs, threats, attitudes, and subjective norms—consistent with research demonstrating support for these models in parenting intervention engagement [61]. These findings also add to the growing body of evidence on engagement in youth mental health services [62,63]. However, the development and testing of theories of family engagement in DHPs will be needed to address barriers and optimize facilitators.

Program Outcomes

Abundant positive changes were highlighted via qualitative interviews. Commonly cited outcomes included direct intervention targets—including parent sensitivity to child errors and child error sensitivity—though broad changes to parenting and parent-child functioning were also described. Changes to beliefs or thinking (eg, reframing mistakes, increased parenting awareness) seemed to reflect evidence of cognitive engagement. These mental shifts were described as preceding behavioral changes. In addition, improvements in child emotional functioning appeared to be driven by changes in parental behavior, although perceived impacts were bidirectional. Participants described additional unanticipated outcomes, including benefits to siblings, other caregivers, friends, family, and community members. Indeed, these descriptions of wide-ranging improvements appeared to reflect a high level of behavioral engagement with *Making Mistakes*, even despite low rates of adherence to the weekly modules.

This apparent discrepancy—that is, abundant perceived positive outcomes and descriptions of strategies enacted, despite low weekly adherence—merits further attention. The findings support distinctions among aspects of behavioral engagement, such as using a DHP's interface, enacting specific techniques learned, and making broader changes to health behaviors [4]. It is possible that the initial in-lab intervention module was an adequate dose for many participants, and subsequent program interfacing was not necessary for broader enactment of concepts learned. Alternatively, the simple weekly reminder texts and emails may have spurred continued improvements, even for those who did not complete the activities. The findings extend the literature on CPE within a DHP, suggesting that cognitive and affective engagement, as well as more "downstream" indices of behavioral engagement, may be more important than traditional metrics of DHP *adherence*. To better understand what constitutes *effective* CPE [3,11], future research may directly compare different behavioral engagement strategies and explicitly link them to outcomes of interest.

Qualitatively, families also commented on the positive impact of study involvement, including participation in dyadic games during the lab, as well as routine outcomes monitoring via error-sensitivity measures [34]. Future research should clarify the relative importance of such nonspecific program components, including measurement and observation procedures. Indeed, given the known benefits of measurement-based care in youth mental health services [64] as well as the potential for observer effects or reactivity in parent-child interaction research [65], participant reports of program-related changes to functioning should be interpreted cautiously.

Enhancements to program design and structure may help to overcome common program-related barriers to participation. Beyond well-established DHP design recommendations, such as customizable reminders and intervention frequency, gamification, human facilitation, ease of access, and appealing content and delivery (eg, [66-68]), this study suggests several additional strategies that may enhance engagement. Participants responded well to psychoeducation about *error sensitivity*, including its causes and consequences, which increased the perceived relevance of the program. Additionally, DHPs and caregiver-mediated programs may be enhanced through options to engage cocaregivers in the program. Moreover, the findings suggested that offering the initial in-lab module, along with parent-child games, and the opportunity to approach the program as a dyadic activity may have facilitated program engagement. Finally, regular reminders (nudges), including periodic assessments, may have driven family investment even in the absence of repeated doses of the intervention content. These potential strategies should be empirically validated in future research.

This study has multiple strengths, including integrated qualitative and quantitative data; demonstration of qualitative rigor and trustworthiness; inclusion of young children in data collection; multiple novel foci (ie, DHPs for 5 to - 7-year-olds,

XSL•FO
RenderX

error sensitivity, preventive parent-child program development); intervention targets derived from a neural marker of anxiety; multiple operationalizations of adherence; and a critical focus on multiple aspects of engagement, a common pitfall of DHPs and of caregiver-mediated interventions [56].

This study must also be interpreted in light of several limitations. Both intervention conditions were housed on the same website, and thus, a few participants accessed a video from the other condition. Thus, analyses focused on rates of adherence by condition should be interpreted with some caution. In addition, our measures of behavioral engagement were somewhat limited, including overall adherence and sustained engagement. Future research should incorporate more dynamic and multidimensional metrics, such as the amount of time spent with the intervention or implementing strategies learned; explore temporal patterns of program participation; or use ecological momentary assessment methods to capture behavioral, cognitive, and affective engagement over time. In addition, though diverse perspectives were represented among the qualitative interviews, external validity is limited by the sample's makeup: mostly White, highly educated, multi-parent homes with relatively high household income. Thus, the results may not be fully generalizable to marginalized families facing additional participation barriers. Future studies must examine *Making Mistakes* engagement in diverse samples.

Conclusion

Preventive programs for young children and families may yield broad-ranging benefits, including transdiagnostic impacts beyond specific intervention targets. Our findings highlight the importance of qualitative assessment in trials of preventive programs and contribute to the sparse literature on prevention programs for young children [69]. The findings also contribute to the broader literature on perfectionism interventions for young people [36], digital health interventions [9,66] including those for preschool anxiety [70,71], and parent-based interventions for young children [72,73].

These findings support further evaluation of a low-intensity preventive intervention, *Making Mistakes*, which shows promise in promoting positive change within error-sensitive families. *Making Mistakes* included a single-session intervention (see [74]) in tandem with brief reminders or nudge interventions [75]. Future iterations of *Making Mistakes* or similar programs could benefit from further tailoring for very young or preliterate children, including the use of verbal recordings instead of written practice assignments. Finally, to meet the diverse needs of families with elevated error sensitivity (see [31]), *modular* DHPs could be developed to prioritize family preferences and accommodate additional areas of concern to the family [76]. Future research should evaluate the long-term impact of *Making Mistakes* and elucidate family engagement in diverse populations. Importantly, family-focused developmental models of perfectionism, including the social expectations, social learning, and anxious rearing models [23,24,31], should guide efforts to develop and implement engaging digital mental health interventions to prevent the development of pediatric anxiety disorders and cultivate resilience in families.

Acknowledgments

We thank Drs Anne Barrett, Michael Kofler, Lyndsay Jenkins, and Walter Boot for their insightful comments and support on an earlier draft of this manuscript, as well as Drs Ryan Coker, Jillian Volpe-White, and Karl Wissemann for their consultations. We deeply appreciate each of the families that participated in our research, especially those who completed qualitative interviews. Finally, we are grateful to the many research assistants who made this work possible, including but not limited to Mia Mantei, Madison Poisall, Sarah Conley, Catalina Borges, Cara Dillhyon, and Mateo Roldan. IAM and AMM were affiliated with Florida State University at the time of data collection. IAM is currently affiliated with the Department of Veterans Affairs/UCSF. AMM is currently affiliated with Santa Clara University.

Generative artificial intelligence tools, including ChatGPT by OpenAI and VA GPT by the Department of Veterans Affairs, were used in the development and editing of code for some quantitative analyses as well as in the preliminary interpretation of select statistical output. The authors take full responsibility for the accuracy, originality, and integrity of all manuscript content.

Funding

This work was funded by the National Institute of Mental Health (grant ID NIMH K01MH117366) and supported by the Department of Veterans Affairs, Office of Academic Affiliations VA Quality Scholars Advanced Fellowship Program (Program Award Number 3Q082019C). The views expressed in this paper are those of the authors and do not necessarily reflect the position or policy of the Department of Veterans Affairs or the United States Government.

Data Availability

The datasets generated and analyzed during this study are not yet publicly available due to the ongoing status of the broader randomized controlled trial. Upon completion of the randomized controlled trial, a portion of the deidentified data underlying this paper will be made publicly available.

Conflicts of Interest

None declared.

Abstract

Background: Infants with complex heart disease often have delayed development, learning difficulties, and mental health problems as they grow older. Their parents and other caregivers engage in online health information–seeking behavior to understand and support their children's health and development.

Objective: In this study, we analyze the presence, nature, and presentation of information about neurodevelopment on the websites of congenital cardiac surgical programs in the United States.

Methods: We used a mixed methods approach, specifically a convergent design. We correlated the presence and presentation of information about neurodevelopment on each program's website with state-level and program-specific factors extracted from multiple publicly available databases. Quantitative analysis methods included descriptive analyses, Student *t* tests, Pearson chi-square test, and multivariate logistic regression analysis, all performed using SPSS (IBM Corp). Qualitative methods included both inductive and deductive content analysis.

Results: Only 39% (50/129) of programs provided any information about neurodevelopment online. High surgical volume correlated with the presence of online information (P<.001). Websites were written at an average 7th to 10th grade reading level, and fewer than 5% of websites had information in a language other than English. Two semantic clusters of website format, content, and element selection were identified, reflecting distinct approaches to adult learners. Program websites clustered into "sage on the stage" and "guide on the side" formats. Few websites incorporated features caregivers previously identified as useful, with only 6% including the four most helpful features.

Conclusions: We highlight the paucity of accessible caregiver-oriented information about neurodevelopment on congenital cardiac surgical programs' websites in the United States and characterize two primary website models. The lack of information may negatively impact caregiver understanding of and engagement with neurodevelopmental services for their child with a congenital heart defect. Future research should explore the impact of each website model on caregiver understanding of and engagement with neurodevelopmental services, as well as the generalizability of these findings to other domains of pediatric subspecialty care.

Introduction

Congenital heart disease (CHD) is the most common type of birth defect, affecting nearly 1% of babies born in the United States every year [1]. Survival has improved with advances in medical and surgical management [2]. As survival has improved, neurodevelopmental impairments have emerged as the predominant morbidity for neonatal heart surgery. Such

XSL•FO
RenderX

impairments in gross motor skills, executive functioning, and mental health are considered one of the primary determinants of quality of life across the patient's lifespan [3-5]. Many of these impairments are amenable to treatment; however, many children do not receive appropriate screening, with parent and other caregiver understanding one likely barrier to screening [6,7].

Parents and other caregivers (grandparents, foster parents, etc) of children with CHD prefer more information than pediatric cardiologists provide, particularly about their child's future quality of life [8]. As with other patients and caregivers, they fill their knowledge gaps using online health information-seeking behaviors [9-13]. Websites rival health care professionals as the most common source of information caregivers use to learn about their child's heart condition (72% - 92% compared with 77% - 92%, respectively), with 30% of those caregivers reporting the use of hospital websites [11,12]. While most parents report searching for information about their child's cardiac condition (88%), many also search for information about long-term outcomes (73%) and challenges associated with CHD (59%) [11]. A handful of studies have evaluated online information about congenital heart defects, but no previous studies have evaluated congenital cardiac surgical program websites, either overall or for information specifically related to the neurodevelopmental impacts of CHD [14,15]. It is unclear if currently available information is adequate to inform caregiver understanding of the need for and engagement with neurodevelopmental supports for their child.

This study analyzes the information about neurodevelopment available on the websites of congenital cardiac surgical programs in the United States. Given heterogeneity in both congenital cardiac surgical outcomes and health care funding and delivery across the United States, we hypothesized that center-specific factors as well as state-level sociodemographic variables would predict the presence, reliability, and models of information provided on these websites.

Methods

Sample Selection

A total sample of all US congenital cardiology surgical programs was defined using the 2021 - 2022 Congenital Cardiology Today directory. Given the impact of funding, politics, and values on institutional priorities and behaviors, a database containing program-specific and state-level characteristics of each program was created. Metrics reflecting the size and robustness of each congenital cardiac surgical program, sociodemographic characteristics of the children in the state being served by each program, and each state's investment in the health and education of children, all extracted from publicly available data, were included in this database (Table 1).

Websites for each congenital cardiac surgical program with information on cardiac neurodevelopment were identified between June and October 2022 using a two-step strategy. First, congenital cardiac surgical program websites were identified. Second, each website was queried for information on neurodevelopment. All web searches described below were conducted by an undergraduate researcher from the Midwest with no prior exposure to the topics of pediatric cardiology or cardiac neurodevelopment.

Website Identification

To maximize search results, a two-pronged approach was used to find congenital cardiac surgical program websites. First, the websites listed in the Congenital Cardiology Today directory were visited. If the listed website was specific to the congenital heart program at that institution, the URL was saved and the splash page was saved as HTML. If the listed website was an institutional website not specific to the congenital heart program, the institutional website search bar was queried sequentially for nontechnical keywords: “heart,” “heart defect,” “heart surgery,” “congenital heart defect,” “pediatric cardiology,” and “cardiac defect.” English language terms were chosen as this is the official language of the country in which all programs were located. Approximating the strategy used by individuals searching for health information online, the first 10 results of each search were reviewed [16]. If a congenital heart program website was found, the URL was saved and the splash page was saved as HTML. This search strategy generated a repository of institutional congenital heart program websites.

Neurodevelopmental Information Identification

Overview

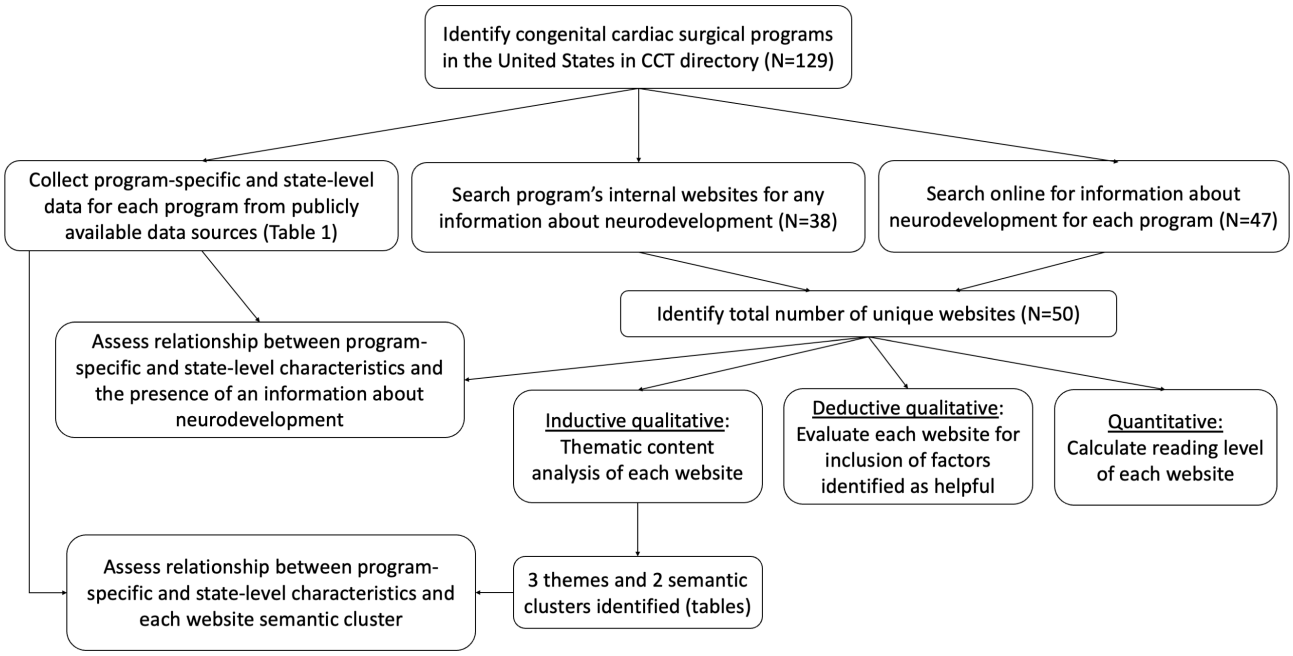
Each congenital cardiac surgical program website was then searched for information about neurodevelopment. Once again, a two-pronged approach was used, this time to allow for the evaluation of internal and external search engine optimization. First, all previously identified congenital cardiac surgical program websites were reviewed to identify the presence of any information related to neurodevelopment. Second, a Google

XSL•FO
RenderX

(Google LLC) search was performed to identify information about cardiac neurodevelopment on the institutional website. The webpages identified using this process formed the units of analysis for subsequent qualitative analysis.

Institutional Website Search

Each congenital cardiology program website, regardless of whether it was identified through the *Congenital Cardiology Today* directory or via a search of the institutional website, was reviewed to identify any information about neurodevelopment. Search terms were preselected and included "development," "neurodevelopment," "neuropsychology," and "brain." If no mention was found on review of each website, the websites were searched using Command-F and through the site search bar on the institutional website. The first 10 results of each search were reviewed [16]. If information about cardiac neurodevelopment was identified, the URL was saved, the splash page was saved as HTML, and all text and images were scraped and archived in the archived qualitative data analysis software Dedoose (Sociocultural Research Consultants, 2022).



Google Search

A Google search for each program's name as listed in the Congenital Cardiology Today directory, in conjunction with preselected keywords, was performed. To maximize search results, keywords were selected based on the verbiage found on the websites of institutions with program websites and included "neurodevelopment," "cardiac psychology," "neurodevelopmental follow-up," and "cardiac neurodevelopment." The first 10 results of each search were reviewed [16]. If a program website was found, the URL was saved, the splash page was saved as HTML, and all text and images were archived as described above.

Mixed Methodology

A convergent mixed methods design was used with parallel quantitative and qualitative analyses, each informing the other (Figure 1) [17]. The central research question was: "How do congenital cardiac surgical programs in the United States communicate information about cardiac neurodevelopment online?" We also asked the subquestion: "Which program-specific and state-level factors impact how this communication occurs?" Results are reported following the Standards for Reporting Qualitative Research [18].

Figure 1. Study design overview. CCT: Congenital Cardiology Today.

Quantitative Analysis

A total population sample requires no inferential statistical analysis because descriptive analysis captures the full population. However, given imperfections in all sampling techniques, univariate and multivariate analysis of program-specific and state-level characteristics correlating with the presence of information about neurodevelopment on congenital cardiac surgical program websites were performed using chi-square tests, *t* tests for the equivalence of the means, and multivariate logistic regression analysis. The program-specific and state-level characteristics are listed in Table 1. For multivariate analysis, surgical programs were binned into even thirds based on surgical volume, with cut points at 125 cases and 270 cases per year, and based on surgical complexity with cut points at <21.75% Society of Thoracic Surgeons–European Association for Cardio-Thoracic Surgery 4+5 cases and >26.75% Society of Thoracic Surgeons–European Association for Cardio-Thoracic Surgery 4+5 cases. Program size was binarized, with larger programs being defined as those with at least 20 cardiologists. Two-sided significance was defined as $P<.05$, and all analyses were performed with SPSS (version 28).

XSL•FO
RenderX

Qualitative Analysis

Inductive Content Analysis

Inductive content analysis of the archived websites was performed between July 2022 and October 2023. This data-driven strategy involves approaching the data without an a priori code book. Instead, a code book is constructed as the data is reviewed in an effort to "remain open to new discoveries" [19]. Codes emerged as the team collaboratively examined the archived websites and created analytic memos documenting their analysis and coding structure. In this fully crossed design, all websites were coded by each coder.

The aims of this analysis were two-fold: (1) to identify semantic clusters based on the types and modalities of information shared on this diverse group of websites; and (2) to situate these clusters within the intersecting geographic, academic, medical, social, and interpersonal spaces occupied by congenital cardiac surgical programs within the United States [20].

Positionality and Reflexivity

The four primary coders have expertise in health equity (DC), psychology (GC), medical anthropology (KRO), and pediatric cardiology (JBA). One is the parent of a child with CHD (JBA). One has studied CHD at two heart centers in the Midwest, one in the urban Pacific Northwest, and one in the urban South (KRO). Two were undergraduate students with no previous exposure to CHD at the time of this study (DC and GC). This study grew out of one author's experience seeking information online about her son's heart defect and its long-term implications (JBA).

Deductive Content Analysis

Language Accessibility

The readability of each website was calculated using multiple measures, including the Flesch-Kincaid readability test, SMOG (Simplified Measure of Gobbledygook) index, and Gunning Fog [21].

Caregiver Utility

Each website was coded for the presence of the top four features preferred by parents of children with CHD [11]. These features include (1) a combination of words, pictures, and videos; (2) descriptions of current research; (3) patient stories; and (4) links to additional websites.

Transparency and Reliability

The transparency and reliability of each website were calculated using JAMA (Journal of the American Medical Association) benchmarks, a streamlined tool to assess "the quality of medical information on the internet" [22]. JAMA benchmarks uses four criteria: authorship, attribution, disclosure, and currency. Scores range from 0 to 4.

Results

Sample

All 129 congenital cardiac surgical programs in the United States listed in the Congenital Cardiology Today Directory were analyzed (Table 2). Only 50 (39%) programs included information about cardiac neurodevelopment on their program website. This information could be found by searching within the program website for 38 programs and via a Google search for 47 programs.

Quantitative Analysis

Five congenital cardiac surgical program–specific factors, and no state-level factors, correlated with the presence of information about neurodevelopment on surgical program websites (Table 3). Only surgical volume retained significance after multivariate analysis: programs averaging more than 270 surgical cases a year were significantly more likely than lower-volume programs to post information about neurodevelopment on their website (P<.001; Table 4).

[e]IDEA: Individuals with Disabilities Education Act.

[f]STAT: Society of Thoracic Surgeons–European Association for Cardio-Thoracic Surgery.

Table . Factors correlated with the presence of information about neurodevelopment on program websites (multivariate analysis).

Program-specific characteristics	Odds ratio (95% CI)	*P* value
Pediatric Cardiology Fellowship Program present	1.1 (0.30-4.40)	.86
Pediatrics residency program present	11.8 (0.80-178)	.07
Surgical volume[a]		
Lowest tertile	Reference	Reference
Middle tertile	3.4 (0.67-17.17)	.14
Highest tertile	65.3 (8.0-531.40)	<.001
Risk category[a]		
Lowest tertile of high-risk cases	Reference	Reference
Middle tertile of high-risk cases	0.5 (0.09-2.54)	.40
Highest tertile of high-risk cases	0.3 (0.056-1.75)	.19

[a]In multivariate analysis, only surgical volume significantly correlated with the presence of online information about neurodevelopment. Society of Thoracic Surgeons participation was excluded due to collinearity with surgical volume and surgical complexity. Programs were stratified into tertiles by ’15-’18 surgical volume and percent Society of Thoracic Surgeons–European Association for Cardio-Thoracic Surgery 4+5 cases. Highest annual surgical volume >270 cases; lowest <125 cases. Highest surgical complexity/risk of mortality >26.75% Society of Thoracic Surgeons–European Association for Cardio-Thoracic Surgery 4+5 cases; lowest <21.75% Society of Thoracic Surgeons–European Association for Cardio-Thoracic Surgery 4+5 cases.

RenderX

Qualitative Analysis

Sample Overview

The final dataset for qualitative analysis comprised 48 websites containing text, images, and videos. Data from one program were corrupted in the archival process, and one program had inadequate information for coding. Website content included information about neurodevelopment, the process for screening, and supports available at the individual institution, descriptions of research into the field, patient and family experiences, and links to external resources. The nature, amount, richness, and technicality of this information varied between programs.

Inductive Content Analysis

Three Cross-Cutting Functions

Taken in its entirety, the content and formatting of each website served three functions: (1) to convey information, (2) to form a connection with the reader, and (3) to establish the competence of the program. The information conveyed, the connection formed, and the emphasis on competence varied from site to site. Most websites described how CHD can alter children's physical, mental, and social development. However, while some focused on how clinicians can help, others focused on the impact of these challenges on the child's quality of life. Similarly, two primary strategies to connect with the reader emerged from the data: some websites used a formal, technical tone to establish authority, while others used a more collaborative style, sharing simplified, practical information. To establish competence, some websites referred to recommendations from organizations such as the Cardiac Neurodevelopmental Outcome Collaborative, American Heart Association, and the National Pediatric Cardiac Quality Improvement Collaborative, while others shared patient stories and testimonials [23].

Two Semantic Clusters

Differences across websites in terms of information conveyed, connection formed, emphasis on competence, and formatting formed the basis of two semantic clusters (Table 5). These two clusters parallel two previously described theories of adult learning and reflect the conceptualization of the institution as either a sage on the stage or a guide on the side [24]. The combined content and formatting used by websites in the first cluster emphasized the value of the services and expertise offered by the sponsoring institution, positioning their respective program as a sage on the stage. The features of the websites in the second cluster emphasized caregivers as partners in their children's development, positioning their programs as guides on the side. Websites that clustered around the sage on the stage model focused on institutional expertise and communicated "who we are and what we do," while those that more strongly reflected the guide on the side model focused on addressing children's needs in partnership with parents or other caregivers and were more effective at sharing "what your child needs and how we can help."

Table . Two semantic clusters were defined by the differential presentation and relative emphases of each website on the congenital cardiac surgical programs' competence, connection to the patient, and services offered.

Function and format	Sage on the stage	Guide on the side
Convey information	Clinician focused: • Centers on the clinician's role • Focuses on technical aspects of clinic visits • Describes research output	Child focused: • Centers on the child's needs • Focuses on practical details of clinic visits • Describes toll of CHD[a] on the entire family
Connect with the reader	Authoritative: • Specialized language and jargon • Technical images and illustrations • Headshots of providers • Emphasizes partnerships with other medical professionals • Shares recommendations from professional organizations	Collaborative: • Plain language • Simplified images and illustrations • Candid pictures of patients and providers • Emphasizes partnership with children and their caregivers • Shares patient stories • Social media links • Requests for donations • Describes patient participation in research
Establish competence	Formal validation: • Awards and certifications listed • Scope and experience of program and providers emphasized	Anecdotal evidence: • Patient testimonials
Format	Formal: • Third person language • Passive voice • Serif fonts, taller than wide • Few or no pictures or videos	Informal: • First or second person language • Active voice • Sans-serif fonts, wider than tall • Pictures and/or videos included

[a]CHD: congenital heart disease.

XSL•FO
RenderX

Sage on the Stage

Websites conforming to the sage on the stage model reflected an authoritative stance (Table 6). Introductory phrases tended to describe services offered by their programs, with a subsequent description of the neurodevelopmental challenges faced by children with CHD. In this way, they centered the institution, not the child. Institutional resources and expertise were emphasized by highlighting staffing, multidisciplinary collaboration, and specialization, as well as by using more technical images and formal typography.

Websites were more likely to use third-person and passive voice to describe both the challenges faced by children with cardiac concerns and the institution's services. While this created a sense of impartiality, it also distanced the author from the reader and weakened the reader's connection to the institution. Families and children were presented as the beneficiaries of partnerships between medical professionals and were described as the participants of, rather than collaborators in, research endeavors.

These features combined to create expert-centered websites, with children as the objects of their expertise, and characterized parents and other caregivers as assistants in their children's care.

Table . Examples of features associated with the sage on the stage websites.

Function and format	Feature description	Examples
Convey informatin	• Centers on the clinician's role • Focus on technical aspects of clinic visits • Describes research output	• The follow-up program, "tracks, monitors and manages the development of children with congenital heart disease who undergo surgical intervention as infants." • "Hammersmith Infant Screen and Bayley Developmental Scales." • "Conduct a range of translational and basic science research." • "Description of research of QI projects in cardiac neurodevelopment."
Connect with the reader: authoritative	• Picture: headshots of providers • Images: technical • Language: specialized/jargon • Partnership: with medical professionals • Appeals to authority	• Cross-sectional image of a 3D rendering of a heart. • "Impaired visual-spatial and visuo-motor skills." • "We partner with each family's local pediatrician to develop a transparent approach to care." • "The American Heart Association and American Academy of Pediatrics recommend that all children with complex congenital heart disease receive regular developmental monitoring."
Establish competence	• Awards and certifications listed • Scope and experience of program and providers emphasized	• "US News and World Report Best Children's Hospitals for Cardiology & Heart Surgery 2022 - 2023 logo. • American Nurses Credentialing Center Magnet Recognition logo. • "As a world leader in pediatric cardiac care." • "We're recognized across the country for establishing the first cardiac developmental follow-up program in the nation." • "The best care in the region for children with heart disease." • "Renowned experts." • "Revolutionary treatments." • "Team includes experts in physical and occupational therapy, speech therapy, a registered dietician, neuropsychologist, and pediatricians. A social worker is also available to support families."
Format: formal	• Third-person language • Passive voice • Font: serif, taller than wide • Few or no pictures or videos	• The heart center, "is dedicated to providing comprehensive care to all of our patients, including monitoring and treatment for any neurodevelopmental disabilities."

XSL•FO
RenderX

Guide on the Side

Websites conforming to the guide on the side model addressed parents and other caregivers directly, using first- and second-person language, and described them as an active part of the team, collaborating with medical professionals to promote their child's success (Table 7). They used plain language and defined technical terminology or jargon as it occurred.

Table . Examples of features associated with guide on the side websites.

Function and format	Feature description	Examples
Convey information	• Centers on the child • Focuses on practical details: insurance coverage, finding parking, paperwork involved, duration of visits, clinic phone numbers, links to online appointment desks, email addresses for coordinators • Describes patient participation in research • Toll of CHD[a] on the whole family	• "Your child's first visit to the Cardiac Neurodevelopmental Clinic involves a thorough screening by providers from many different medical services. Each is an expert in a specific area of pediatric growth and development. This exam will take about 3 hours." • "Some families have found it helpful to bring snacks, drinks, toys or books to occupy their children during the appointment." • "Having a child with a serious heart condition…may leave you with a jumble of thoughts and feelings, including anger and grief….any and all thoughts or feelings you experience during this time are normal."
Connect with the reader: collaborative	• Pictures: candid pictures and videos of patients and providers • Images: simplified • Language: plain • Partnership: with families • Patient stories • Social media links • Requests for donations • Research: invitation to participate	• Image of a female health care provider in a medical setting sharing a teddy bear dressed in scrubs with a girl in a wheelchair. • Image of a female nurse providing hands-on care to a female infant following open-heart surgery in an intensive care setting. • "Neurodevelopment is a term that describes how our brains grow and form connections that direct our function and behaviors." • Links to Facebook (Meta), SnapChat (Meta), Twitter (formerly known as Twitter; X Corp), LinkedIn (Meta), Instagram (Meta), and YouTube (Google LLC) accounts. • "We'll be right by your side providing care." • "Together, we will decide if any other support or programs can help your child." • "If families and children are willing, voluntary participation in clinical research studies remains the cornerstone of the process."
Establish competence	• Patient testimonials	• "Website section: "Stories to Inspire." • Stories about children at home with their families.
Format	• First/second person language • Active voice • Font: sans-serif, wider than tall • Pictures or videos included	• "We look forward to partnering with you to help your child reach their fullest potential." • We will refer you to "specialists in your community who can help your baby reach key developmental milestones, such as walking and talking."

[a]CHD: congenital heart disease.

Visual and verbal storytelling provided another mechanism for demonstrating mutual respect and building personal connections. Candid images of providers interacting with children in both inpatient and outpatient settings powerfully illustrated the relationships that can develop between children and their medical team. They also highlighted the approachability of these providers. Written accounts of children's challenges and successes invited the reader to imagine what the best possible outcome for their child might look like and reminded them that they are not alone on their journey. Solicitations for donations or research participation similarly invited readers to partner with the institution to further the work of caring for children with CHD in developmentally appropriate ways.

XSL•FO
RenderX

These features combined to create websites that were patient-centered, respected caregiver authority, and promoted collaboration in the care of children with CHD.

Degree of Conformity

Few websites reflected a single pattern; rather, combinations of various elements on each website conformed more or less closely to one or the other. About half (25/48, 52%) of program websites conformed most closely to a guide on the side model, 40% (19/48) of them reflected a sage on the stage model, and 8% (4/48) of them had overlapping features of both. Websites from larger programs (≥20 cardiologists) were statistically more likely to follow a guide on the side model (20/28 vs 5/16, χ^2_1=6.7, *P*=.01). No other program- or state-level characteristics correlated with a program conforming to one vs the other learning model.

Deductive Qualitative Analysis

Language Accessibility

All but two program websites were written above a 6th-grade reading level, with an average reading level between the 7th and 10th grade (Flesch-Kincaid mean 9.9, SD 2.4, Gunning Fog mean 9.0, SD 2.9, SMOG index mean 7.6, SD 1.9). Only two websites had information in a language other than English. Both offered information in Spanish.

Caregiver Utility

No more than one-third of websites included any one of the individual website features that most parents of children with CHD identified as useful. Only three program websites included all four features (Table 8).

Table . Inclusion of website features parents find useful.

Characteristic	Values, n (%)
A combination of words, pictures, and video	5 (10)
Descriptions of current research	16 (33)
Patient stories	16 (33)
Links to additional websites	16 (33)
All features	3 (6)

Transparency and Reliability

Of the 48 programs with codable data, the average JAMA benchmarks score was 1.5/4. Only four websites listed any authors, all of whom were authors for attached or embedded files, not for the main website. While nearly all programs included a copyright date on their website, only 1 program included information on when the website was most recently updated, with 3 other programs including the publication dates of attached or embedded files. A total of 15 programs cited sources for statements made on their website.

Discussion

Principal Findings

This study outlines the current paucity of information about neurodevelopment shared online by congenital cardiac surgical programs, identifies barriers to parents and other caregivers accessing that information, and identifies two website models corresponding to two models of adult learning.

Comparison With Prior Work

Overview

Despite the potential neurodevelopmental impacts of CHD, children's receipt of developmentally supportive care is inconsistent, and both short- and long-term outcomes remain variable [6,7,25-27]. Many factors associated with children receiving neurodevelopmental follow-up (hospital-initiated scheduling, antenatal diagnosis, and longer postoperative length of stay) suggest that caregiver understanding facilitates receipt of this care. Increased parent and caregiver education may improve follow-up with anticipated positive downstream impacts on patient outcomes [6]. Given caregivers' reliance on online sources of health information and their documented use of congenital cardiac surgical program websites, these sites may be one venue to provide such education.

Limited Searchable Information About Cardiac Neurodevelopment

Parents and other caregivers of children with CHD report that online resources help them better understand their child's diagnosis and the information from their child's health care team. However, approximately a quarter of parents note that information about their child's cardiac diagnosis is difficult to find online [11]. This study expands upon this parental observation, finding that only 39% (50/129) of congenital cardiac surgical programs in the United States include any information about one of the biggest contributors to these children's quality of life, the neurodevelopmental sequelae of CHD, on their institutional websites. Due to poor search engine optimization, this information was difficult to find, with only 38 programs having information that could be found by a search of their institutional website and 47 having information that could be found via a Google search.

This lack of searchable information is troubling, as more than a third (39%) of parents and other caregivers report using websites, not their child's health care provider, as their primary source of information about their child's heart condition [12]. These numbers are higher for caregivers of patients on public insurance (45%) and caregivers with less than a high school education (48%). These children from socioeconomically disadvantaged backgrounds, whose parents and other caregivers rely more on online sources of information, are the same children who experience higher rates of mortality, longer lengths

XSL•FO
RenderX

of stay, and higher medical costs following cardiac surgery [25-27]. This suggests a disproportionate impact of this missing information on those children already at risk for worse outcomes.

Language and Literacy Barriers

Parents and other caregivers face additional challenges accessing information, even when it is included on congenital cardiac surgical program websites. In this study, all but two program websites were written above a 6th-grade reading level, with an average reading level between the 7th and 10th grade. In addition, despite nearly 20% of US adults being foreign-born, many of whom speak English as a second language, in this study, only two congenital cardiac surgical program websites offered information in a language other than English [28].

Lower socioeconomic status, lower educational attainment, and speaking English as a second language are all associated with both lower literacy and lower health literacy [28,29]. Lower health literacy is associated with worse health outcomes in both children and adults [30-32]. No studies have explored the relationship between parent or other caregiver health literacy and outcomes following childhood cardiac surgery. However, children who live in lower-income neighborhoods, further from a specialized congenital cardiac surgical center, and who have public (as opposed to private) insurance have higher rates of mortality, longer lengths of stay, and higher medical costs following cardiac surgery [25-27]. This suggests that health literacy may be one of the mediators of health outcomes in these children and supports the American Heart Association recommendation that all health care communication be "accessible at any level of health literacy" [33].

Many medical organizations offer guidance on health care communication, for both print and online materials. The Joint Commission recommends that health care organizations know "the language needs and literacy levels of the population and community served" [34]. Practical recommendations can be found in the Health Literacy Universal Precautions Toolkit, created by the Agency for Healthcare Research and Quality [35]. Recommendations include having staff members skilled in assessing, selecting, and creating written materials that are easy to act on; obtaining patient feedback on written materials; routinely assessing whether written materials are easy to understand; and providing materials in the preferred language of the patients cared for.

The use of features that parents and other caregivers of children with CHD have previously identified as useful may also improve comprehension for parents and other caregivers with limited health literacy. These features include using a combination of words, pictures, and videos; sharing patient stories; and sharing summaries of recent research [11]. These features were infrequently found on the websites reviewed in this study, with each feature being found on no more than a third of the websites visited, and only three websites including all four features.

Sage on the Stage and Guide on the Side

Most surprisingly, we identified two semantic website clusters corresponding to two established adult educational models: the sage on the stage and the guide on the side. Those websites adhering to the sage on the stage model emphasized institutional expertise, reflecting an authoritarian and patriarchal stance toward patients and their loved ones. Those conforming more closely to the guide on the side model emphasized parental partnership and centered the patient and family experience with humility and empathy, reflecting a family-centered model of care.

Educational researchers continue to debate the relative merits of each model in promoting adult learning [24,36]. It remains to be seen if one, the other, or a combination of both models is most palatable to the parents and other caregivers of children with CHD and whether such differences impact parental follow-up adherence, parental stress, and child developmental outcomes.

Recommendations for Congenital Cardiac Program Website Development

Congenital cardiac surgical program websites have the potential to improve parents' and other caregivers' understanding of their child's unique developmental and mental health needs. This study reveals a lack of relevant information on surgical program websites, poor search engine optimization, language barriers, and a lack of features preferred by parents. To improve website effectiveness, there are several steps website developers can take (Textbox 1). These include the following: (1) including content about the developmental and mental health impacts of CHD; (2) performing internal and external search engine optimization; (3) removing language barriers by limiting jargon, using plain language, and providing information in their patients' preferred languages; (4) including more features that caregivers find useful; and (5) including links to local resources. These simple changes could increase the impact of existing websites by helping caregivers recognize the anticipated neurodevelopmental sequelae of their child's CHD and access services to support their child's development.

XSL•FO
RenderX

Textbox 1. Recommendations for website developers.

1. Include information about neurodevelopment.
2. Perform internal and external search engine optimization (use metadata tags such as “cardiac neurodevelopment,” “development,” “ADHD,” and “neuropsychology”).
3. Write website content at a level that parents and patients can understand (sixth-grade reading level or below with active voice, no jargon, short paragraphs, and simple illustrations).
4. Provide information in the languages spoken by patients and their caregivers.
5. Include website features that parents of children with CHD find useful (a combination of words, pictures, and videos; descriptions of current research; patient stories; and links to additional resources).
6. Include links to local, community-based resources.

Additional improvement could be realized by institutional application of the principles underpinning the guide on the side model—empathy, humility, and collaboration—through the process of human-centered design [37]. By seeking out and incorporating parent and other caregiver perspectives at all stages of website development, institutions could identify the preferred model of content delivery (sage on the stage vs guide on the side) for patients and families in their catchment area and develop strategies for cognitive alignment. Centering the parents and other caregivers of children with CHD will allow for optimized delivery of accessible, impactful, and usable information.

Limitations

There were several methodological limitations. While this study intended to include a total population sample of all programs performing congenital cardiac surgery in the United States, 1 surgical program was not included in the Congenital Cardiology Today directory for 2021 - 2022, and data for 1 program were lost during the archival process. While hospital catchment areas vary in size, from portions of a city to multiple states, this study compared congenital cardiac surgical programs to state-level sociodemographic data and may have missed local or regional factors. In addition, STS (Society of Thoracic Surgeons) Congenital Cardiac Public Reporting Data from 2015 - 2018 was used instead of 2019 - 2023 data. More recent data encompasses surgical volumes and outcomes during the height of the COVID-19 pandemic, which varied substantially from surgical program operations both before and after the pandemic, which would have skewed the data [38,39].

All web searches were conducted in English without the use of incognito mode, or clearance of caches and cookies, potentially influencing search results and leading to either missed or enhanced identification of neurodevelopmental information due to the heavy personalization of search engine algorithms based on browsing history. While many congenital cardiac surgical programs have a social media presence, this study did not evaluate their social media. This was an intentional choice, as more caregivers of children with CHD report using websites than social media (72% - 92% vs 20%, respectively) to learn about their child’s health and development [11,12]. Finally, the choice of inductive content analysis facilitated analysis of what was present on program websites, but not an analysis of potentially useful features that were absent, such as links to or descriptions of how to access local, community-based early intervention programs.

Next Steps

This analysis of information about neurodevelopment on the websites of congenital cardiac surgical programs invites future inquiry into both the topic at hand and the broader application of our findings to other pediatric medical subspecialties. First, what are parents’ and other caregivers’ impressions of available information, and how does the way in which the information is presented (guide on the side vs sage on the stage models) impact follow-up adherence, caregiver stress, and children’s outcomes? Second, how does health literacy mediate disparities in health and neurodevelopmental outcomes in children with CHD? Third, what is the quality of other online sources of information (nonprofit and governmental websites, social media sites, and parent support groups) about the neurodevelopmental outcomes of children with CHD? Finally, do these findings generalize to other areas of pediatric medical subspecialty care, and can we leverage our presentation of online information to improve children’s outcomes across multiple domains?

Conclusions

CHD is a complex, lifelong condition that creates ongoing informational needs for impacted patients and their parents and other caregivers. Neurodevelopmental impairments are the number one morbidity of CHD. Public-facing information about cardiac neurodevelopment on the websites of congenital cardiac surgical programs is sparse, with high-volume surgical programs being the most likely to have any information at all. For websites that do include this information, linguistic factors and poor search engine optimization create additional barriers for parents and other caregivers to access this information. Websites reflect two models of adult learning: the guide on the side, which emphasizes caregivers as key stakeholders and partners in their children’s development, and the sage on the stage, which emphasizes the value of the services and expertise offered by the sponsoring institution. Future studies should evaluate which, if either, model is preferred by caregivers or more strongly influences caregiver behaviors and patient outcomes. This would allow for the development of content that promotes caregivers’ pursuit of optimal neurodevelopmental supports for their children and may have application to other areas of pediatric medical subspecialty care as well.

Abstract

Background: Spina bifida (SB) is a congenital condition that requires long-term multidisciplinary medical collaboration for treatment. Previous research has primarily focused on the negative impacts experienced by caregivers of children with SB. However, with the development of positive psychology, the concept of benefit-finding (BF) has been explored in the context of caregivers of children with various chronic illnesses. Nonetheless, in Japan, BF among caregivers of children with SB remains unexplored, and no appropriate measurement tool has been developed for this population.

Objective: This study aimed to translate and validate the Japanese version of the University of Washington Caregiver Benefit Scale (UW-CBS) based on caregivers of children with SB and to examine the characteristics of BF in these caregivers. A comparative analysis with caregivers of able-bodied children was also conducted to elucidate the parenting stress and social support experienced by families rearing children with SB.

Methods: This 2-part study was carried out from January 2024 to December 2024. In Study 1, the UW-CBS was translated, then face validity was examined through a pretest (n=6) using cognitive interviews. In the main survey, construct validity, known-groups validity, and retest reliability were evaluated (n=60). In Study 2, the characteristics of BF of caregivers of children with SB were analyzed using data from the main survey. Parents of able-bodied children (n=66) completed the same questionnaire. Parenting stress, BF, and social support scores were then compared between caregivers of children with SB and the parents of able-bodied children.

Results: In Study 1, the reliability and validity of the UW-CBS were examined. Internal consistency was high (Cronbach α=0.92), while test-retest reliability had an intraclass correlation coefficient of 0.62 (*P*=.051). In Study 2, caregivers who had a partner (*P*=.009) and those who were rearing both a child with SB and a sibling reported higher levels of BF (*P*=.02). Compared with families rearing able-bodied children, no significant differences emerged in BF or parenting stress, but the level of social support was significantly higher in families of children with SB (*P*=.005).

Conclusions: This study demonstrated the reliability and validity of the Japanese version of the UW-CBS in families rearing children with SB. For caregivers of children with SB, assistance from other family members or shared childcare responsibilities may facilitate positive adjustment. Moreover, the higher level of social support received by caregivers of children with SB may mitigate their parenting stress and foster their perception of benefits.

spina bifida; benefit finding; caregivers; parenting stress; social support

Introduction

Spina bifida (SB) is a congenital disorder caused by incomplete closure of the neural tube that is generally accompanied by a variety of disorders, such as hydrocephalus, cognitive difficulties, bladder and bowel incontinence, and ambulatory dysfunction [1]. The management of SB requires not only multidisciplinary collaboration but also individualized care from caregivers because its clinical manifestations vary widely, with

XSL•FO
RenderX

severity primarily determined by the level of spinal cord lesions. Caregivers of children with SB often face a range of challenges, having to balance the demands of long-term medical care, such as urinary and fecal incontinence [2], while also focusing on their child's education and future [3].

Previous studies have primarily focused on the negative impacts of rearing children with SB, such as parenting stress [4,5]. A meta-analysis showed that families of children with SB and other chronic illnesses face the highest parental stress levels, highlighting the need for interventions aimed at improving marital relationships, enhancing social support, and equipping parents with strategies to manage parenting stress [6]. Compared with families with typically developing children, families of children with SB report higher levels of parenting stress related to managing children's behavior, reflecting the challenges they face in addressing complex caregiving demands [7]. Further research has shown differences in stress sources between parents of children with SB: Fathers experience greater stress when dealing with children's maladaptive behaviors and insufficient social support, whereas mothers' stress is more closely related to the medical characteristics and dysfunction of the children [8]. Age also emerges as a significant factor affecting maternal parenting stress because older mothers report higher stress levels [9,10]. Among the medical factors, Kanaheswari et al [11] identified clean intermittent catheterization as the only significant contributor to maternal parenting stress in families of children with SB. Moreover, ongoing issues such as limited mobility and bladder and bowel dysfunction in school-aged children also contribute to persistent stress among parents of children with SB [12].

In the process of coping with parenting stress among caregivers of children with SB, social support may play a buffering role. Studies have shown that higher satisfaction with social support is closely associated with greater positive emotional adjustment in mothers [13]. Greater support from the family is also strongly linked to better physical health in mothers [14]. Furthermore, greater levels of social support are strongly related to fewer behavioral problems in children [8,15,16]. Notably, Feldman et al [16] demonstrated that social support plays a crucial moderating role between parenting stress and child adaptation. The aforementioned studies demonstrate that social support plays a critical role in multiple aspects of rearing children with SB. Meanwhile, further research underscores that, in pediatric rehabilitation settings, the importance of social support for families of children with SB cannot be overlooked [17]. In addition to mitigating negative emotions, social support contributes to the positive adjustment of caregivers. A study focused on caregivers of children with developmental disorders suggested that social support facilitates cognitive adaptation, thereby promoting positive emotional changes in caregivers [18].

Although caregiving challenges are substantial in families of children with SB, the demands associated with caregiving roles may create opportunities for personal growth and positive adaptation. Benefit-finding (BF) refers to the recognition of positive life changes that emerge from the process of coping with difficult life events [19]. Research on BF often focuses on the patients themselves [20-22], but caregivers of patients also experience BF. An increasing number of studies have reported positive changes, such as BF in caregivers of children with chronic illnesses [23-25]. In a qualitative study involving nuclear family members of children with chronic food hypersensitivity, a hierarchical BF process model was constructed. The findings suggested that parental modeling and reinforcement facilitated the sharing of positive experiences among family members [25]. This process highlights how BF emerges within families including children with chronic illness as a dynamic mechanism, where shared positive experiences not only strengthen individuals but also contribute to the overall harmony of the family unit.

In the context of SB, a study focused on young adults with SB found that the most prominent aspects of BF they experienced were related to personal strengths, interpersonal relationships, and life philosophy [26]. In addition, Kritikos et al [27] developed a BF scale specifically for individuals with SB based on a sample of 20 adolescents and young adults with SB. Although caregivers of children with SB are likely to experience more challenges, their special caregiving roles may also foster opportunities for positive psychological adaptation. However, research on BF by parents of children with SB remains limited, and the experiences of these families in different cultural contexts, such as Japan, have yet to be fully explored. Whereas the study by Kojo and Fukumaru [28] found that parents of children with SB tend to report high levels of depression, there remains a notable gap in understanding other characteristics, such as BF, parenting stress, and social support, of families of children with SB in the Japanese context.

In Japan, the existing caregivers' BF scale was tailored specifically to caregivers of children with developmental disabilities [29], leaving a gap in measurement tools that adequately capture the BF experiences of caregivers of children with SB. The University of Washington Caregiver Benefit Scale (UW-CBS) developed by Amtmann et al [30] was designed to measure BF by caregivers regardless of whether their children have a medical condition. The flexible design of the UW-CBS makes it suitable for assessing BF in a variety of caregiving contexts.

Overall, this study sought to measure BF to explore the positive changes experienced by caregivers of children with SB. However, because no suitable scale exists in the Japanese context, the first objective of this research was to translate the UW-CBS into Japanese and evaluate its reliability and validity within the Japanese context. As little research in the Japanese context has focused on parenting stress, BF, and social support among caregivers of children with SB, the second goal of this study was to examine the current status of parenting stress, social support, and BF of caregivers of children with SB and clarify the unique characteristics of families of children with SB by including parents of able-bodied children as a comparison group.

Methods

This research consisted of 2 parts and was carried out from January 2024 to December 2024.

XSL•FO
RenderX

Study 1

Aim

Study 1 aimed to translate the UW-CBS [30] into Japanese and evaluate its reliability and validity using an anonymous cross-sectional questionnaire survey of caregivers of children with SB. To ensure the cultural equivalence and face validity of the UW-CBS, a small-scale pretest incorporating cognitive interviews was conducted, after which, the UW-CBS was revised for application in the main survey. Based on the Consensus-Based Standards for the Selection of Health Measurement Instruments (COSMIN) risk of bias checklist [31], an adequate sample size for cognitive interviews is 4 to 6 participants, and more than 30 participants is considered adequate for a quantitative main study.

Preparation

The International Society for Pharmacoeconomics and Outcomes Research [32] Good Practice for the Translation and Cultural Adaptation Process was adopted as the methodological framework. With the consent of the original author, the target population was defined as caregivers of children with SB. The research team consisted of 2 native Japanese speakers fluent in English with extensive experience in nursing research, together with a bilingual researcher involved in the study.

Forward Translation and Reconciliation

With the consent of the original author, 2 native Japanese speakers (TK and AY) independently translated the UW-CBS scale into Japanese. Discrepancies were discussed within the research team, and consensus was reached on the overall translation, with particular attention paid to the Japanese expressions of “feel closer” and “accepting person” and the use of sentence connectors to ensure natural and conceptual clarity. This reconciliation process resulted in Version 1, which was subsequently back-translated into English by the third bilingual researcher (XC). The back translation demonstrated conceptual equivalence with the original version.

Pretest and Cognitive Debriefing

Adult caregivers of children with SB were recruited using snowball sampling. After recruitment, questionnaires were mailed to the participating caregivers in advance, and subsequently, cognitive interviews were conducted with 6 caregivers via a videoconferencing application (Zoom Video Communications) or telephone. During this process, the time required to complete Version 1 of the UW-CBS was recorded. Using a verbal probing approach, caregivers were asked to comment on response ease, item clarity, discomfort in answering, relevance, and alignment with their experiences [33].

To explore caregivers’ BF experiences further, an open-ended question was included in the questionnaire, followed by approximately 30-minute interviews based on the caregivers’ responses. All interviews were audio-recorded and transcribed verbatim.

During the cognitive interviews, the caregivers indicated that the referent of “other person” was ambiguous. To address this issue, clarification was sought from the original author to ensure that the intended meaning was preserved in the translated version. Based on the feedback obtained, the research team discussed and refined Version 1 of the UW-CBS, resulting in Version 2.

Responses to the open-ended questions were qualitatively coded and categorized by one researcher (XC), with subsequent review and agreement within the research team.

Back Translation, Review, and Proofreading

Following an additional review by the research team to ensure wording and grammatical accuracy, back translation was performed by Editage, an independent professional translation service. Subsequently, the back translation was submitted to the original author for verification and formal approval.

Main Survey and Retest

Using Version 2 of the UW-CBS, the main survey was subsequently conducted (n=60). Caregivers of children with SB aged younger than 16 years were recruited through two methods. Caregivers undergoing treatment for depression or managing other children’s intensive care conditions were excluded. The caregivers’ responses were collected through both paper-based and online (Research Electronic Data Capture [REDcap] platform) methods. Among the caregivers of children with SB recruited through snowball sampling, 8 agreed to participate in the retest. The retest was conducted 2 weeks to 3 weeks after completion of the initial questionnaire and yielded 7 valid responses.

Questionnaire: Pretest

UW-CBS

The UW-CBS [30] is a publicly available, psychometrically sound instrument designed to measure the positive impacts of caregiving on adults. The UW-CBS is an item response theory–based tool composed of 13 items that evaluate the perceived benefits of caregiving, such as appreciation of life, discovering new strengths, and personal growth. Responses are rated from 1 (“Not at all”) to 5 (“Very much”), and scores are converted into an item response theory–based T-score to reflect BF levels. The UW-CBS has demonstrated good validity and reliability, with high test-retest reliability (intraclass correlation coefficient [ICC] >0.92) and strong internal consistency (Cronbach α=0.89). Moreover, to facilitate its use in diverse populations, the UW-CBS has been translated into Spanish, German, French, and Italian [34], demonstrating its potential as an internationally applicable tool for measuring the positive aspects of caregiving.

Open-Ended Responses

To investigate whether caregivers of children with SB experience unique aspects of BF, the following open-ended question was included: “While rearing a child with spina bifida, have you noticed any other aspects of your life where you have experienced positive changes?”

Parenting Stress Index-Short Form

The Japanese version of the Parenting Stress Index-Short Form (PSI-SF) [35], originally developed by Abidin as the Parenting Stress Index (PSI) [36], was used to assess parenting stress. The

XSL•FO
RenderX

PSI-SF consists of 19 items rated on a 5-point scale and measuring 2 subdomains: parent-related (10 items) and child characteristic-related (9 items) stress scores. Responses range from 1 (“Not at all”) to 5 (“Exactly so”), with higher scores indicating higher levels of parenting stress. The PSI-SF has also been specifically adapted for use with Japanese parents to ensure cultural relevance.

Japanese Short Form of the Multidimensional Scale of Perceived Social Support

The Japanese short form of the Multidimensional Scale of Perceived Social Support (JMSPSS) [37] is derived from the original scale developed by Zimet et al [38], which uses a 7-point Likert-type scale ranging from 1 (“Not at all”) to 7 (“Very much”), with higher scores indicating greater perceived social support. The JMSPSS has a 3-factor structure: family support, significant other support, and friend support. The overall Cronbach α coefficient for reliability is 0.91, indicating good internal consistency.

Tachikawa Resilience Scale

The Tachikawa Resilience Scale (TRS) [39] is a 10-item self-reported measure designed to assess the resilience of Japanese individuals. In this study, the TRS was used to assess the construct validity of the UW-CBS. The TRS uses a 7-point Likert-type scale, ranging from 1 (“Not at all applicable”) to 7 (“Very applicable”), with higher scores indicating greater resilience. The Cronbach α coefficient of the TRS is 0.90, indicating good internal consistency.

Demographic Characteristics

Child-related items included age, sex, bladder condition (International Consultation on Incontinence Questionnaire-Urinary Incontinence Short Form, urinary incontinence, clean intermittent catheterization use and independence), bowel condition (bowel management and method, bowel movement independence, fecal incontinence, bowel management caregiver), mobility status, and shunt utilization of the child with SB; total number of children; and presence of significant illnesses in other children.

Caregiver-related items included age, relationship to the child, educational background, marital status, current mental illness, and self-reported life satisfaction.

Data Analysis

The qualitative data from the pretest were transcribed verbatim, and interview data on BF experiences were analyzed using qualitative descriptive induction [40], which involves coding and categorization.

For the main survey, quantitative data were analyzed using SPSS for Windows (version 29; IBM Corp), with a significance level of $P<.05$. Descriptive statistics were used to summarize the demographic characteristics and the results from the administered scales. In this study, differential item functioning (DIF) was examined across gender and age using ordinal logistic regression, with McFadden $R^2<0.02$ as the criterion [31]. Reliability was evaluated by calculating the Cronbach α coefficient for internal consistency and using the 2-way random effects (2,1) ICC for test-retest reliability. Construct validity was examined by analyzing the correlation between the UW-CBS and TRS. Given the conceptual relatedness between BF and resilience and prior evidence reported in the original study ($r=0.28$) [30], we hypothesized that the UW-CBS would be weakly positively correlated with the TRS. Known-groups validity was also evaluated. Caregivers of children with more severe medical conditions were hypothesized to have higher BF based on prior evidence that posttraumatic growth is higher in more severe and life-threatening medical contexts [41]. Similarly, caregivers with a spouse were hypothesized to have higher BF based on evidence linking marital adjustment and spousal support with greater resilience [42] and psychological health [43] among caregivers of children with chronic developmental conditions.

Study 2

Aim

Study 2 sought to gain a deeper understanding of caregivers rearing children with SB in the main survey by including a control group consisting of the parents of able-bodied children. In the comparison, caregivers of children with SB constituted the SB group, and parents of able-bodied children constituted the able-bodied group. An anonymous cross-sectional survey was conducted to assess BF, parenting stress, and social support, with a subsequent analysis to compare differences between the two caregiver groups.

Comparison Between the SB Group and Able-Bodied Group

The members of the SB group were the participants in the main survey of Study 1 (n=60). Parents of able-bodied children (n=67) were recruited using the following 2 approaches: (1) a family-supporting specified nonprofit corporation (NPO) and (2) a participant recruitment company. The exclusion criteria included caregivers who were receiving treatment for depression or caring for their own children with conditions requiring intensive care. Parents recruited from the NPO responded to the questionnaire through REDcap.

Questionnaire

The same questionnaire used for the main survey of Study 1 was used. Regarding the UW-CBS, the Cronbach α coefficient in the able-bodied group was 0.96.

Data Analysis

We used 1-way ANOVA, independent samples *t* tests, Mann-Whitney *U* tests, and χ^2 tests to measure the characteristics of caregivers of children with SB and the differences between the SB and able-bodied groups. Cohen *d* (≥0.8 for a large effect) indicated the effect size.

Ethical Considerations

This study was approved by the Osaka University Hospital Ethics Committee (approval number: 23426‐4). Prior to participation, all participants received an information sheet explaining the purpose and procedures of the study, and informed consent was obtained through the consent confirmation section of the questionnaire. Participation was voluntary, and participants could withdraw from the study at any time without

XSL•FO
RenderX

penalty. The questionnaire survey was conducted anonymously, and no personally identifiable information was collected. Data were managed using identification numbers and stored securely in locked cabinets and password-protected computers accessible only to the research team. Participants received a ¥500 (US $3.17) gift card as appreciation for their participation.

Results

Study 1

Pretest

Participants

In the pretest, 9 caregivers of children with SB were recruited; however, 1 was lost to follow-up, and 2 were unable to participate in the interview, resulting in a final sample of 6 caregivers. The 6 caregivers took approximately 2 minutes to complete the UW-CBS.

Validity Assessment

During the face validity cognitive interview, although a few concerns were raised about items 1, 2, 3, 5, and 12, the majority of caregivers indicated that these items were clear and easy to understand. For example, regarding the item "Are you a better advocate for your child/children because of caregiving?," the caregivers mentioned that they felt confident in doing well when their child was younger. However, now that their child has his/her own opinions, they were uncertain about whether they fully and accurately convey their child's intentions. For item 10, which used the Japanese translation of the term "accepting person," most caregivers found the translation understandable but remarked that its phrasing felt slightly awkward. Thus, item 10, "accepting person," was revised to more natural Japanese phrasing without altering its meaning. Overall, the caregivers indicated that most items were clearly expressed and successfully conveyed the intended meaning.

BF Experiences

Interviews with open-ended questions were conducted to explore the BF experiences that emerged among caregivers in the process of rearing their children with SB. The results identified several key aspects of BF: psychological and emotional growth, improvement of knowledge and skills, expansion of social support networks, changes in perspective, and planning for the future.

Psychological and Emotional Growth

For instance, caregivers initially used blogs as a way to gather information about SB and connect with other caregivers in similar situations. Over time, their focus shifted from seeking support to providing it:

> *By starting the blog, I felt that I was able to connect with other children who have the same illness, and that it might also be helpful for children who will be born in the future.* [Caregiver C]

Improvement of Knowledge and Skills

Caregivers not only actively sought information about SB itself but also developed an understanding of how to use assistive devices commonly needed by children with SB, such as wheelchairs and lower-limb orthoses. In addition, caregivers' curiosity expanded beyond SB, leading them to explore information about children with other chronic conditions:

> *Information about leg braces—such as the different types, their names, how to use them, and why they are worn…* [Caregiver E]

Expansion of Social Support Networks

Caregivers expanded their social support networks by connecting with other parents of children with SB or chronic illnesses through activities such as their children's participation in sports or blogging. These interactions provided some level of support and practical insights, which helped them navigate the challenges of caregiving more effectively:

> *We talk about things like different types of wheelchairs. Even when there isn't a specific problem to consult about, we stay connected on a regular basis.* [Caregiver C]

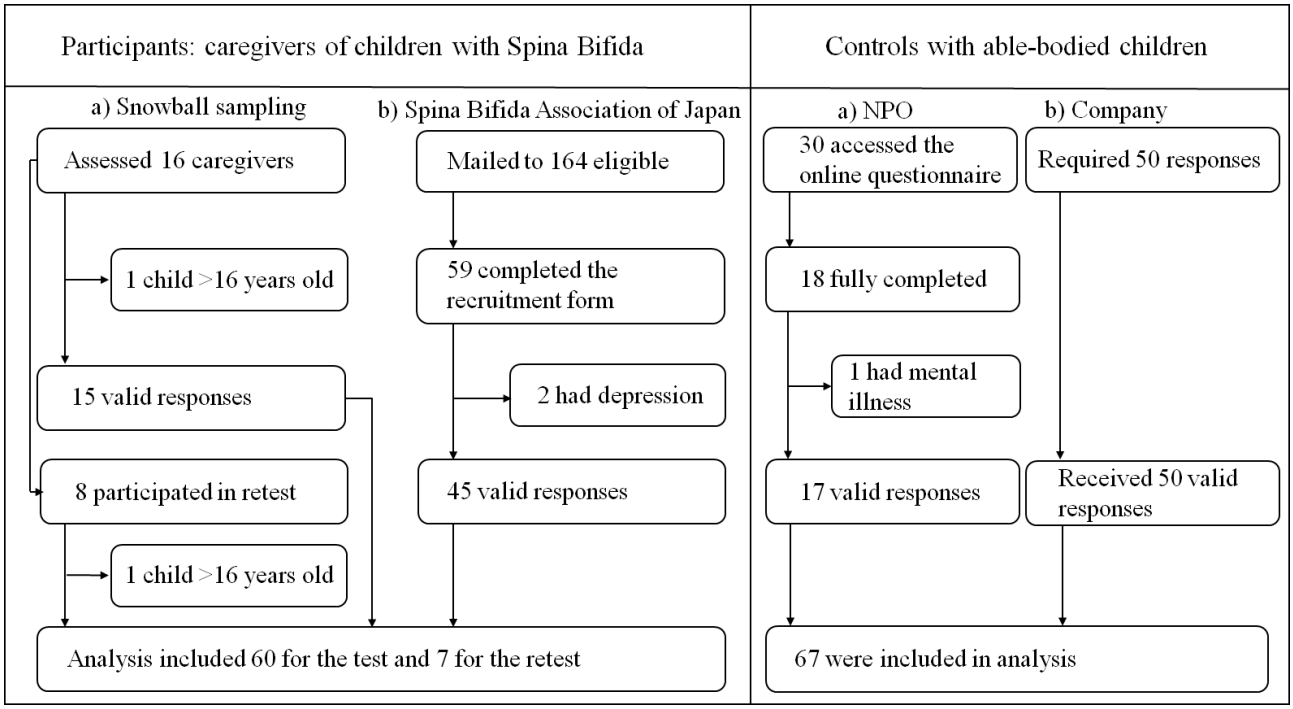
Changes in Perspective

Rearing a child with SB gradually led caregivers to adopt new perspectives in certain areas. For example, caregivers began to see things from the perspective of disabilities; they stated that they focus on celebrating small daily achievements rather than comparing their child with others, emphasizing a mindset of progress and acceptance:

> *It made me realize that there are so many different conditions out there, and I began to pay more attention to that.* [Caregiver A]

Planning for the Future

Due to the unique needs of children with SB, caregivers found it necessary to make more detailed plans for the future, particularly regarding schooling and other key aspects of their child's development:



> *We had submitted a request, and arrangements were made so that an elevator would be properly installed in time for the child's school enrollment.* [Caregiver A]

Main Survey

Through snowball sampling, 16 caregivers of children with SB were recruited, 8 of whom participated in the retest of the UW-CBS, as shown in Figure 1. Two responses (1 main survey and 1 retest) were excluded because the child was older than 16 years.

XSL•FO

Figure 1. Recruitment processes in this study. NPO: specified nonprofit corporation.

The study introduction was sent by mail to 164 members of the Spina Bifida Association of Japan. Among these, 45 caregivers completed the questionnaire online (2 reported depression), while 2 responded via mail. The respondents' demographic characteristics are summarized in Table 1. DIF was assessed across gender and age using ordinal logistic regression analysis, and all McFadden R^2 values were <0.012.

Total scores on the UW-CBS	43.20 (10.31)	44.00 (45.00)	53.51	32.90	N/A[a]

[a]Not applicable.

Reliability

The Cronbach α coefficient for the UW-CBS was 0.92. A total of 7 participants completed the retest, and the ICC yielded a result of 0.62 (*P*=.051).

Validity

The correlation between the TRS and UW-CBS was *r*=0.30 (*P*=.02), aligning with the hypothesis. Known-groups validity was examined by comparing UW-CBS total scores across groups defined by children's medical severity and caregivers' marital status. In both comparisons, the groups hypothesized to have greater BF showed higher UW-CBS total scores (Table 3).

Study 2

Characteristics of BF in Families of Children With SB

The UW-CBS scores for each characteristic are presented in Table 1. Two results with significant differences were identified: Single mothers reported lower UW-CBS scores (t_{58}=2.68, *P*=.009; *d*=0.95), and caregivers rearing only children with SB reported lower UW-CBS scores (t_{58}=2.40, *P*=.02; *d*=0.75). The results are shown in Table 4.

Table . Characteristics of caregivers (n=60) of children with spina bifida with regard to University of Washington Caregiver Benefit Scale (UW-CBS) scores.

Characteristic	Sample size, n	UW-CBS score, mean (SD)	*t* value (*df*)	*P* value	Cohen *d*
Total number of children			2.40 (58)	.02	0.75
1	15	37.80 (9.18)			
≥2	45	45.00 (10.12)			
Caregivers' relationship status			2.68 (58)	.009	0.95

Correlations Between BF, Parenting Stress, and Social Support Among Families of Children With SB

The JMSPSS had a significant positive correlation with the UW-CBS (*r*=0.30, *P*=.02) and a significant negative correlation with the PSI-SF (*r*=–0.47, *P*<.001). Although the correlation between the UW-CBS and the PSI-SF was not statistically significant, a negative association was observed (*r*=–0.22, *P*=.90).

Comparison Between the SB and Able-Bodied Groups

Comparison of Demographic Characteristics

For the able-bodied group, a total of 18 participants completed the questionnaire through recruitment by the NPO. One answer was excluded because the respondent reported a mental illness but declined to disclose the specific diagnosis. In addition, 50 parents of able-bodied children were recruited through the company. To ensure comparability, the characteristics of the SB and able-bodied groups were compared, but no significant differences were found.

Comparison of Scales

The results of the comparison of each scale between the groups are shown in Table 5. The analysis comparing the 2 groups revealed no significant difference in UW-CBS nor PSI-SF scores, but the SB group had higher JMSPSS scores (*U*=1428.50, *P*=.005).

XSL•FO
RenderX

Table . Results regarding the distribution of and the Mann-Whitney *U* or independent samples *t* tests of the University of Washington Caregiver Benefit Scale (UW-CBS), Parenting Stress Index-Short Form (PSI-SF), and Japanese short form of the Multidimensional Scale of Perceived Social Support (JMSPSS) scores between the spina bifida (SB; n=60) and able-bodied (n=67) groups.

Scale	SB group		Able-bodied group		Mean difference	
	Mean	Median	Mean	Median	Statistical test result	*P* value

Discussion

Study 1

The aim of Study 1 was to translate the UW-CBS into Japanese and validate its reliability and validity through a pretest and main survey. Because the UW-CBS was not developed in an Asian context, cognitive interviews were conducted as a critical step to address potential cultural differences in the process of scale adaptation. Overall, nearly all caregivers were able to understand the meaning of all items and found most of them to be clearly expressed. However, caregivers also experienced some hesitation and confusion while responding to certain items. Similar feedback was also provided when the UW-CBS was translated into European languages [34], suggesting that, although the scale is broadly applicable, some conceptual nuances require careful adaptation.

Regarding reliability, internal consistency was high (Cronbach α=0.92), but test-retest reliability yielded an ICC of 0.62 (*P*=.051), which did not reach the level of statistical significance. This marginal result likely reflects a lack of statistical power due to the small sample size (n=7) rather than the inherent instability of the scale. However, given that the original version demonstrated robust stability and our qualitative findings confirmed the items' conceptual clarity, these results provide a preliminary indication of the scale's reliability.

In adapting the UW-CBS to Europe, the mean score (44.50) was lower than that in the United States (47.90) [30]. In Japan, this study yielded an even lower mean score (43.20). In addition to the issues caregivers encountered while responding, this phenomenon may also be attributed to the cultural differences between Asian and Western contexts. Compared with those in the United States, Japanese adults report higher levels of pessimism and are less positive [44]. In addition, adults in the United States perceive self-esteem as both desirable and consequential, whereas Japanese people view self-esteem as desirable but not consequential [45]. Japanese respondents tend to use rating scales more moderately [46], which may also lead to lower observed mean scores. These differences in cultural perspectives may partially explain why the UW-CBS scores observed in this study were lower in the Japanese context, as a more pessimistic outlook and less emphasis on self-esteem may reduce the likelihood of identifying benefits in caregiving situations. In addition, interviews with caregivers about their BF experiences while rearing children with SB revealed several recurring themes, including psychological and emotional growth, improved knowledge and skills, expanded social support networks, changes in perspective, and planning for the future. The results of the semistructured interviews on BF indicated that experiences related to BF exist within caregivers of children with SB, and the themes appear to align with the content of most items on the UW-CBS, suggesting a potential connection between the scale's construction and the lived experiences of the target population.

In the main survey, no ceiling nor floor effects were observed for the 13 items on the UW-CBS, and the total score followed a normal distribution. The absence of meaningful DIF across gender and age, indicated by McFadden R^2 values <0.012, suggests that the UW-CBS demonstrates measurement stability. In addition, the overall Cronbach α coefficient for the Japanese-translated UW-CBS was 0.92. Whereas the original study reported that this correlation was lower than anticipated, the result obtained in this study was similar to the original result. A retest with 7 caregivers was conducted, and the test-retest reliability was 0.62, lower than that in the original study (0.92). Although the result in this study was not significant, likely because of the small sample size, the ICC of 0.62 still suggests that the UW-CBS demonstrates a certain degree of reliability. Construct validity was examined by exploring the correlation between the resilience scale and the UW-CBS. In this study, the correlation was *r*=0.30 (*P*=.02), which is comparable to the original study's correlation of *r*=0.28 (*P*<.01). The known-groups validity comparisons identified differences in BF between caregivers of children with SB who differed in

XSL•FO
RenderX

medical condition, as indicated by ventriculoperitoneal shunt use, as well as between caregivers with and without a partner, in the expected directions. These findings suggest that the UW-CBS is capable of capturing meaningful variation in BF across caregiver subgroups.

Study 2

The aim of Study 2 was to explore the characteristics of caregivers of children with SB. Because little research has explored BF among caregivers of children with SB, we first examined the characteristics of their scores on the UW-CBS. We found that parents rearing only children with SB scored lower on the UW-CBS than did those who were also rearing other children without serious conditions. This result suggests that a greater number of children may offer caregivers increased emotional support or family resources, which may foster more positive emotional experiences. Previous research concerning parents of children with autism spectrum disorder has indicated that parents and siblings themselves believe that they mature more quickly as a result of taking on a caregiver role [47]. Furthermore, in a study of resilience among families of children with autism, interviewers also noted that siblings tend to look after the child with autism, thereby bringing family members closer together [48]. These findings may also be applicable to families rearing children with SB, where the presence of additional children may contribute to the development of a stronger support network among family members, thereby influencing caregivers' perceptions of BF.

In this study, caregivers with partners had higher UW-CBS scores. This result aligns with previous research emphasizing the importance of marriage, as marital satisfaction contributes to improved psychological adjustment [6] and positive child adjustment outcomes [49]. Another study highlighted that a partner's companionship is an indispensable source for mothers of children with SB, which cannot be easily substituted by other forms of social support [50]. By contrast, single mothers of children with SB reported significantly higher parenting stress [7,11], suggesting that the absence of a partner may exacerbate parenting challenges. Further research should place greater emphasis on providing support for single-parent families of children with SB.

The comparison between caregivers of children with SB and parents of able-bodied children resulted in a significant difference in social support scores, but no significant differences were observed in parenting stress nor BF. The significant difference in social support may stem from the extensive medical needs of children with SB, which often require ongoing help from health care professionals and social workers. In addition, caring for a child with SB can lead caregivers to connect with others in similar situations, further expanding their support networks. These assumptions are partially supported by the pretest findings, in which the category *Expansion of social support networks* emerged. Caregivers mentioned having access to help from specialists in areas like rehabilitation and welfare during difficult times, as well as forming friendships with other caregivers of children with SB.

In prior studies, caregivers of children with SB reporting higher levels of social support also tended to report lower parenting stress [8,16] and distress [13]. Despite the fact that parents of children with SB have generally reported higher levels of parenting stress in most studies [6-12], greater social support may account for the finding in this study that caregivers of children with SB experience levels of parenting stress comparable to those of parents rearing able-bodied children.

Although the original UW-CBS paper reported higher BF scores in community samples compared with those in medical condition samples [30], in this study, no significant difference in UW-CBS scores was found between caregivers of children with SB and the control group. This result may be attributed to the relatively high levels of social support received by the caregivers of children with SB in this study. A study focusing on caregivers of children with developmental disabilities explored a BF-related model, identifying a positive relationship between social support and BF while suggesting that social support nourishes framework reconstruction and potentially facilitates the BF process [18]. This finding raises the possibility that caregivers of children with SB, as fellow caregivers of children with chronic conditions, might experience a greater degree of BF in the context of a well-developed social support network.

Limitations

This study has some limitations. First, the recruitment of caregivers was inherently challenging because of the medical complexity and care demands associated with SB, and recruitment was further constrained by the COVID-19 pandemic. As a result, the sample sizes for the main survey and retest were relatively small, which limited the statistical power. In particular, test-retest reliability did not achieve statistical significance, suggesting that the results regarding the scale's stability should be interpreted as preliminary. Second, the validation of the scale was restricted to caregivers of children with SB as the target group. In future research, the application of the UW-CBS is anticipated to be examined in larger sample sizes and among a broader range of caregivers of children with special needs to evaluate the stability and measurement properties of the UW-CBS. Second, because this study had a cross-sectional design and measured BF at a specific point in time, longitudinal research should be considered to gain a deeper understanding of the positive psychological adaptation process of parents of children with SB within the Japanese context. Third, the recruitment strategy, which relied on associations and snowball sampling, may have led to an overrepresentation of caregivers with higher levels of social support. This may reduce the representativeness of the study sample. Future studies should adopt broader and more systematic recruitment strategies to enhance representativeness and reduce potential selection bias.

Conclusions

This study, based on the context of Japanese caregivers of children with SB, translated and validated the UW-CBS, demonstrating its usability. In addition, BF was observed in families of children with SB, with more pronounced levels in families simultaneously rearing typically developing children and in households with a spouse or partner. Families of children with SB also reported receiving greater levels of social support than parents of able-bodied children.

Abstract

Background: The 42 days following childbirth are a high-risk period for birthing individuals and newborns. We created 2 rule-based chatbots, 1 for birthing individuals and 1 for newborn caregivers, to deliver information on postpartum and newborn warning signs, follow-up care, and other relevant resources during this high-risk period.

Objective: This study aims to examine strategies for implementing the chatbot following discharge from a large hospital center, initial chatbot reach, and subsequent reach after chatbot refinement based on end-user feedback.

Methods: Reach was defined as the number of users opening the chatbot out of those who received it. Birthing individuals' demographic (age, ethnicity, race, language, and insurance type) and clinical characteristics (delivery method and prenatal care location) and newborns' time in the hospital were obtained from the medical record. Descriptive statistics, chi-square tests, and multiple logistic regression models were used to analyze the association between demographic and clinical characteristics and chatbot reach.

Results: Both chatbots were developed and revised based on clinician, community, and patient feedback. Overall, 65.9% (4933/7489) of newborn caregivers discharged between October 2, 2022, and January 15, 2025, opened the newborn chatbot, and 63.6% (4140/6505) of birthing individuals discharged between November 21, 2022, and January 15, 2025, opened the postpartum chatbot. Older age (odds ratio [OR] 1.02, 95% CI 1.01-1.03), Black race (OR 0.73, 95% CI 0.61- 0.88; reference: White), languages other than English or Spanish (OR 1.90, 95% CI 1.21-2.98; reference: English), receipt of prenatal care external to the hospital system (federally qualified health center: OR 0.52, 95% CI 0.45-0.60; Kaiser: OR 0.34, 95% CI 0.29-0.39; reference: within the hospital system), and public insurance (OR 0.72, 95% CI 0.64-0.82; reference: private insurance) were significant predictors of postpartum chatbot reach. Older age (OR 1.02, 95% CI 1.01-1.03), Black race (OR 0.61, 95% CI 0.50-0.74; reference: White), receipt of prenatal care external to the hospital system (federally qualified health center: OR 0.50, 95% CI 0.44-0.57; Kaiser: OR 0.30, 95% CI 0.26-0.35; reference: within the hospital system), public insurance (OR 0.63, 95% CI 0.55-0.71) and self-pay (OR 0.56, 95% CI 0.38-0.83; reference: private insurance), and newborn time in the hospital of 2 - 4 days (OR 1.21, 95% CI 1.09-1.35; reference: less than 2 d) were significant predictors of newborn chatbot reach. Including a Spanish-language version in the newborn chatbot improved reach among Spanish-preferring caregivers (from 58% to 66.2%), but additional chatbot content revision and the addition of chatbot information to discharge paperwork did not change chatbot reach.

Conclusions: While there were differences in chatbot reach by patient demographics, the chatbot showed delivery of time-sensitive information and support to >60% of individuals. This intervention demonstrated that chatbots can be used to supplement patient care and help bridge the gaps in connecting patients to care and support after hospital discharge. Future work should address additional ways to improve chatbot reach and explore the impact on targeted health outcomes.

Introduction

The 42-day period after childbirth is widely viewed as high-risk both for the birthing individual and for the newborn [1-3]. Access to timely information about potential warning signs for when to seek emergency care, along with proper follow-up care and support, has the potential to improve maternal and infant health outcomes after discharge from the hospital. Top causes of death for birthing individuals in the 42-day period after delivery are mental health conditions, cardiovascular conditions, and infections [4], while top causes of mortality among infants are birth defects, preterm birth and low birth weight, and sudden infant death syndrome [5]. Previous work has cited the importance of monitoring women post-delivery, with an estimated 15% of severe maternal morbidity cases occurring after discharge [6]. Furthermore, a prior randomized control trial found that enhanced caregiver education via SMS text messaging, timed to the infant's age and most common reasons for emergency department visits, reduced emergency department visits in infants' first year of life [7]. In recent years, SMS text messaging services such as Text4Baby (National Healthy Mothers, Healthy Babies Coalition and Voxiva) [8,9] and apps such as BabyScripts (1EQ, Inc) [10,11] have been developed to provide information to patients during the prenatal and postpartum periods on maternal and infant health.

Chatbots are another mobile health (mHealth) strategy used to deliver timely information. Maternal chatbots are an acceptable and feasible strategy for postpartum and caregiving information and support [12,13]. For example, Rosie is a chatbot that leverages artificial intelligence (AI) to deliver personalized assistance related to pregnancy, labor, postpartum care, and newborn care [13,14]. Another chatbot, Dr. Joy, is an obstetric and mental health-related question-and-answer knowledge-based chatbot that also leverages AI for prenatal and postpartum care [15]. While these chatbots are effective in disseminating relevant health information among select patients, they have been deployed in small trials, as opposed to part of standard of care.

We developed and piloted 2 rule-based chatbots (one for birthing individuals and one for newborn caregivers) to provide timely health information and resources, including connection to care. This study aims to describe the process of developing and piloting an mHealth program aimed at improving education on postpartum and newborn warning signs and appropriate connection to care and resources after hospital discharge. We also aim to describe the chatbot reach (number of patients who opened the chatbot out of those who received it) among patients discharged from a large mid-Atlantic hospital that serves a socioeconomically and racially diverse population overall. We assessed reach after initial launch and after refining the chatbot in response to patient feedback. We hypothesized that with each chatbot refinement, there would be an improvement in reach. Finally, we explored how individuals' demographic and clinical factors were associated with reach for each chatbot.

Methods

Overview

This study was prepared in accordance with the iCHECK-DH (Guidelines and Checklist for the Reporting on Digital Health Implementations) [16].

Chatbot Development, Initial Implementation Strategies, and Setting

The postpartum and newborn chatbots were developed as part of a larger initiative, Safe Babies Safe Moms (SBSM), which was aimed at reducing infant and maternal disparities in the District of Columbia (DC) [17]. These chatbots were designed with key goals of helping patients connect with care teams (eg, information about recommended pediatric and postpartum appointments, list of pediatricians in the area), educating them on warning signs, and providing additional postpartum and newborn information and resources (eg, breastfeeding and wound healing after C-section) [18]. The chatbots operated on a rule-based system with fixed logic for interaction (ie, patients could not ask open-ended questions). Content was developed by a multidisciplinary team of experts in obstetrics, pediatrics, social work, psychiatry, mHealth, and health equity, designed to meet the needs of diverse patients.

We created 2 separate chatbots to account for instances where a birthing individual and newborn did not go home together (eg, adoption, surrogacy, neonatal intensive care unit, or postpartum complication) and provide appropriate information at the appropriate time. Thus, within a nonprofit health care system, caregivers of newborn patients discharged at a large, mid-Atlantic hospital between August 29, 2022, and January 15, 2025, received the newborn chatbot, and birthing individuals discharged between November 21, 2022, and January 15, 2025, received the postpartum chatbot within 24 hours of hospital discharge as standard of care. Individuals discharged after January 15, 2025, did not receive the chatbots due to the funding period ending.

The postpartum chatbot messages were sent in the morning, delivering messages weekly for the first 42 days post-discharge (Figure 1 and Multimedia Appendix 1). The newborn messages started 24 hours after discharge, asked about whether a newborn visit was scheduled, offered support and resources when the caregiver answered no, and followed up with weekly informational outreach messages. A total of 7 messages with unique content were sent for the postpartum chatbot, and 5 messages were sent for the newborn chatbot. Each unique set of chatbot content is referred to as an experience. The topics included in each chatbot experience are listed in Table 1. In short, topics included appointment reminders, warning signs, nutrition recommendations, and developmental milestones for newborns and postpartum care. Both postpartum and newborn messages were sent as standard of care to all individuals who delivered at the hospital, except for one community clinic that opted to only implement the newborn chatbot because they already had a postpartum follow-up process and did not want to confuse patients. There was some content tailoring in the

XSL•FO
RenderX

postpartum chatbot; for instance, birthing individuals who had a C-section received information about wound care.

XSL•FO

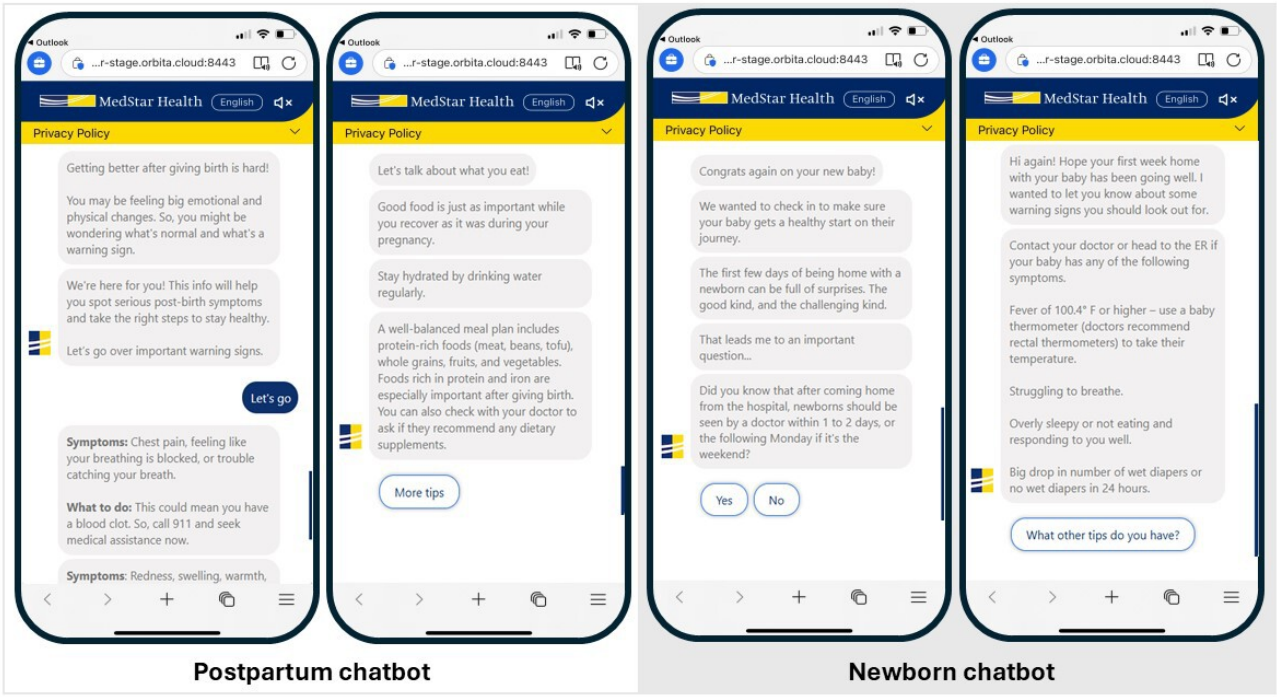
Table . Newborn and postpartum chatbot reach for caregivers and birthing individuals, and topics covered by each chatbot experience.

Experiences and topics covered in the chatbot[a]	General reach by experience, n/N (%)
Newborn chatbot experience[b]	
Experience 1 (day 1 post discharge)	
Original: pediatric appointment reminder; resources to address common challenges for scheduling an appointment (only offered to patients without an appointment); parental leave	1757/4438 (39.6)
Revised: pediatric appointment reminder; resources to address common challenges for scheduling an appointment (offered to all patients); parental leave	1285/2935 (43.8)
Experience 2 (day 7)	
Original: pediatric warning signs; newborn sleep recommendations	930/4384 (21.2)
Revised: pediatric warning signs; newborn sleep recommendations (added recommendations for premature newborns)	652/2989 (21.8)
Experience 3 (day 14)	
Original: newborn nutrition recommendations; resources for breastfeeding and formula; food assistance program	973/4320 (22.5)
Revised: newborn nutrition recommendations; resources for breastfeeding and formula; colic education; newborn bowel movement education; food assistance program	691/3053 (22.6)
Experience 4 (day 28)	
Original: newborn developmental milestones	1104/4192 (26.3)
Revised: pediatric 1-month visit; tips for communicating with providers; newborn developmental milestones; recommended activities with newborns	886/3181 (27.9)
Experience 5 (day 38)	
Original: recommended pediatric visits and vaccines	1608/4104 (39.2)
Revised: 2-month checkup and recommended vaccines; support groups; resources for diapers and baby essentials	1126/3269 (34.4)
Postpartum chatbot experience[c]	
Experience 1 (day 1 post discharge)	
Original: postbirth warning signs; baby blues	1336/3895 (34.3)
Revised: postbirth warning signs; baby blues and recommendations	907/2610 (34.8)
Experience 2 (day 3)	
Original: postbirth warning signs; postpartum check-up; recovering after a C-section; resources to address common challenges for scheduling a postpartum check-up	1317/3874 (34)
Revised: postbirth warning signs; postpartum recovery; recovering and management after a C-section or vaginal birth; breastfeeding tips and resources; pain management; paid family leave	846/2631 (32.2)
Experience 3 (day 7)	
Original: nutrition	903/3846 (23.5)
Revised: nutrition and resources; stress management tips, postpartum check-up and resources to address common challenges for scheduling or attending a postpartum check-up	544/2659 (20.5)
Experience 4 (day 14)	
Original: postpartum depression; sleep recommendations	691/3794 (18.2)
Revised: postpartum depression; sleep recommendations and tips	390/2711 (14.4)
Experience 5 (day 21)	
Original: family planning and sex after birth	1002/3728 (26.9)

XSL•FO
RenderX



Experiences and topics covered in the chatbot[a]	General reach by experience, n/N (%)
Revised: family planning and sex after birth	706/2777 (25.4)
Experience 6 (day 28)	
Original: pelvic floor - Kegel exercises	656/3660 (17.9)
Revised: physical activity; Pelvic floor - Kegel exercises	511/2845 (18)
Experience 7 (day 42)	
Original: social support; postpartum depression	413/3560 (11.6)
Revised: social support and resources; resources for postpartum depression; health care after birth	250/2945 (8.5)

[a]The topics covered in each experience were revised, and the new content for all experiences was launched on February 21, 2024, for both chatbots. Thus, the total number of patients who received the new content will differ by experience.

[b]Caregivers of newborns discharged from the hospital between October 2, 2022, and January 15, 2025, received the newborn chatbot. A total of 116 caregivers who received the newborn chatbot were excluded due to missing data by experience.

[c]Only birthing individuals discharged from the hospital between November 21, 2022, and January 15, 2025 received the postpartum chatbot.

Figure 1. Chatbot screenshots of the postpartum and newborn chatbots.

Electronic Health Record Data Extraction and Integration

The chatbot system relied on structured electronic health record (EHR) data to identify discharge dates for birthing individuals and newborns. A native EHR data extraction program using Cerner Command Language was designed to retrieve relevant patient information including contact information, preferred language, and prenatal care provider. The data extraction was fully automated and ran daily. These data were securely transmitted to the chatbot vendor system via the enterprise Interface Engine using secured File Transfer Protocol to ensure end-to-end transport layer security, consistent with industry-standard security practices. Upon receiving the contact list, the chatbot vendor delivered the chatbot content through SMS text messaging and email. The vendor generated daily analytics files that included user reach metrics (eg, overall chatbot use) that were securely transferred back to the health care system.

Study Design and Participants

This is a pragmatic implementation study where we described the strategies used to develop the postpartum and newborn chatbots and performed a cross-sectional analysis to evaluate the postpartum and newborn reach. Because patients received the chatbots as standard of care, we included all the birthing individuals and caregivers of newborn patients discharged from a large, mid-Atlantic hospital in the data analyses. Newborn chatbot reach was evaluated for newborn patients discharged from October 2, 2022, to January 15, 2025, who received the newborn chatbot. We were unable to report chatbot delivery and reach during the first month of chatbot launch due to inconsistent documentation by the vendor; these issues were resolved during team meetings. For postpartum reach, all

XSL•FO
RenderX

birthing individuals discharged from November 21, 2022, to January 15, 2025, and who received the postpartum chatbot were included in the analysis.

Measures

Implementation Strategies and Chatbot Reach

The chatbots were designed to fill a gap in follow-up after patient discharge, particularly among those patients who did not seek care within the health care system before or after birth. Implementation strategies specific to increasing reach and engagement for the chatbot focused on developing stakeholder relationships, reexamining implementation, and engaging consumers. The primary outcome of this analysis is chatbot reach and is defined as the number of people who opened the chatbot link out of those who received outreach messaging. Chatbot reach data were obtained from the chatbot vendor, and the research team linked the data back to the patient's medical record.

Demographic and Clinical Data Collection

Birthing individuals' and newborns' demographic and clinical characteristics were obtained from the EHR. These independent variables were categorized as follows: birthing individual age (<20, 20‐29, 30‐39, 40+ years), ethnicity (Hispanic or non-Hispanic), race (Black or African American, White, other, or unknown), preferred language (English, Spanish, other [eg, Amharic, Arabic, French, etc], or unknown), and insurance type (private or commercial, public, other, self-pay, or unknown). Regarding medical history, we included delivery method (vaginal birth or C-section) for the birthing individuals, newborns' weight at birth (very low birthweight: <1500g, low birthweight: 1500g to <2500g, or normal birthweight: ≥2500g), gestational age (<37 wk or ≥37 wk), time in the hospital between birth and discharge (<2 d, 2‐4 d, or >4 d), and prenatal care location (care within the MedStar Health system where they delivered, Kaiser [where both care and insurance are provided within the same system], other external clinics (largely federally qualified health centers [FQHCs] or unknown sources of care). Birthweight and gestational age data were only available for newborns discharged from October 2, 2022, to September 30, 2024, as they were obtained from the EHR for a prior SBSM project [17].

Data Analysis

We used descriptive statistics to describe reach and chi-square tests to evaluate demographic and clinical factors related to the postpartum and newborn chatbot reach. We also assessed changes in reach after modifying chatbot outreach and content. We used backward selection of the independent variables (birthing individual age, ethnicity, race, preferred language, insurance type, and prenatal care location) to finalize the multivariate logistic regression models. For the postpartum chatbot reach, we also included birthing individual delivery method (vaginal vs cesarian), and for the newborn chatbot, we included time in the hospital. In addition, we tested the impact of adding birthweight and gestational age as independent variables to the newborn chatbot logistic regression limiting the population to the date range October 2, 2022, to September 30, 2024, (as these 2 variables were only available between these dates).

Ethical Considerations

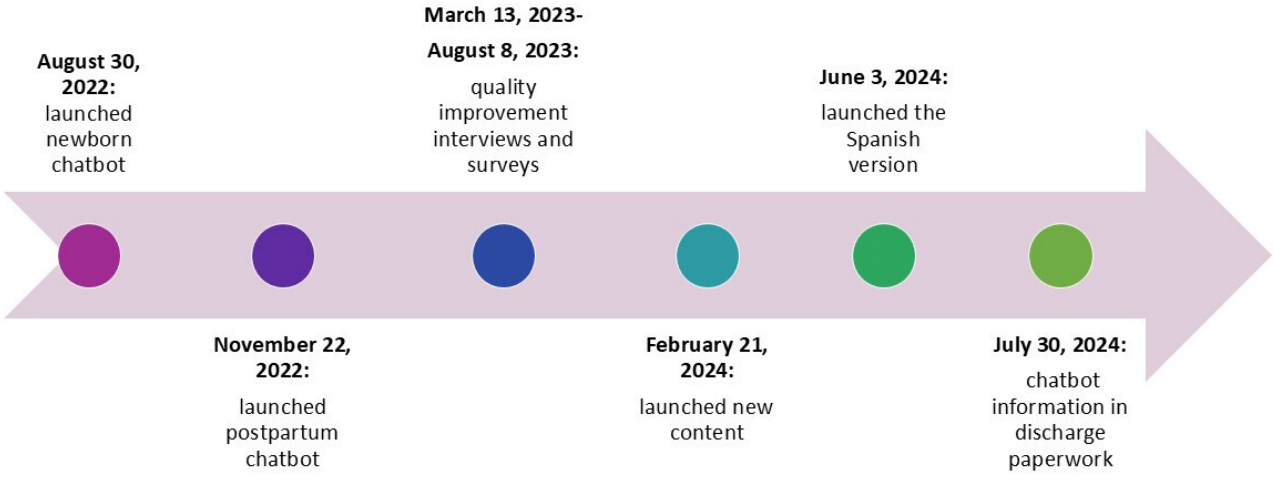
The study protocol was approved by the Institutional Review Board (IRB) from MedStar Health Research Institute (IRB #5741). This project was completed in accordance with the ethical standards of the MedStar Health Research Institute IRB and the Helsinki Declaration of 1975 and the 2000 revision. We did not ask for consent or compensate patients in this study as the chatbots were automatically sent to patients as standard of care. Our IRB granted a Health Insurance Portability and Accountability Act waiver to link chatbot engagement to the patients' demographic and clinical data (eg, age, race, preferred language, type of insurance, and prenatal care location). Identifiers were needed to link patients to their relevant EHR information. All patients' identifiers were deleted from all files after data analysis was completed.

Results

Implementation Strategies

Developing Stakeholder Relationships

Before developing the chatbot, we met with the clinical leaders in labor and delivery, including physicians, nurses, and administrators. We also consulted with our community partners on key content and outreach strategies, as two-thirds of those delivering at the target hospital seek prenatal and postpartum care outside of the hospital's health care system. We then identified a lead in each of the clinical areas involved (pediatrics, labor and delivery, and behavioral health) to help with the development of the chatbot content.



We iteratively developed the chatbot content, incorporating feedback from birthing individuals and caregivers (n=9) recruited from two pediatric clinics, who reviewed the content and participated in an individual semistructured interview. We notified providers and health care system leaders once the program was ready to launch and invited feedback on integration with existing workflows. Throughout this project, clinical leads were invited to participate in scientific abstracts to increase a sense of buy-in and were given opportunities to reflect on progress. Additionally, we presented ongoing successes and challenges to the parent project's strategic advisory board, which includes clinical and community maternal and infant health equity experts, to solicit feedback. In response to provider feedback about the busy pace and competing priorities of the labor and delivery unit, we automated outreach to eliminate any need to ask providers to enroll patients. Despite the automation, building stakeholder relationships was vital to ensure that clinical teams were comfortable with their patients receiving the outreach, optimize the outreach content, and increase the likelihood that they would support introducing it into discharge paperwork.

XSL•FO
RenderX

Iterative Processes, Including Purposefully Re-Examining the Implementation and Reaching Consumers

The timeline for chatbot launch and iterative refinement is shown in Figure 2. The research team met with the chatbot vendor weekly to review data. With input from the research team, the vendor created a dashboard to monitor reach and certain engagement metrics (eg, user response to the question about scheduling their first newborn pediatric appointment). After assessing baseline rates of reach and preliminary engagement, between March and August of 2023, we collected qualitative and quantitative feedback from diverse users (46% identified as Black, 25% as Hispanic, and 54% had public insurance) to solicit input on increasing reach and use of chatbot content [18].

Figure 2. Postpartum and newborn chatbot implementation and refinement timeline.

Based on initial reach data and patient feedback (reported elsewhere [18]), we created the following changes: (1) we modified the outreach messages to include more information about each week's content, (2) we added relevant topics and resources within each chatbot experience (revised topic content listed in Table 1), (3) we translated the chatbot content into Spanish, (4) we added information about the chatbot to the discharge paperwork so that patients who reviewed the paperwork might have a frame of reference for the outreach.

The outreach messages were changed from a generic script to specify the topics covered in the corresponding experience. Overall, language was revised to improve readability and clarity (eg, "postpartum" was replaced with "after giving birth"). The chatbot content was changed in various ways (Table 1). First, we added additional tailored information for recovery after a C-section or vaginal birth, and options to read more about breastfeeding, with sensitivity to patient experiences around whether they chose to or were able to breastfeed. Second, additional resources such as Maternal Mental Health Hotline, Postpartum Support International, Breastfeeding Center of Greater Washington, and Safe Sleep Program from DC Department of Health were added. Third, we included a voice-over feature to facilitate reviewing the chatbot information using audio, as well as an option for patients to download the content as a PDF so that they could refer back to the information and share it with their partners or family members. We reviewed the revised content with 5 patients at an obstetrics clinic and 5 caregivers at a pediatric clinic to solicit in-person feedback via brief interviews. The interviewer took structured notes on patients' and caregivers' recommendations to share with the study team. Recommendations included: slowing down the speed that chatbot messages added text, shortening the messages, bolding the most important information, and adding a summary of the information included in the shared links. The speed at which new messages appeared in the chatbot was slowed to 2500 milliseconds, and we divided the information into more segments where patients could choose response options. This allowed us to shorten the messages and increase the potential for interaction within the chatbot. The updated outreach messages and chatbot content were launched on February 21, 2024.

A Spanish version of each chatbot was implemented on June 3, 2024, after professional translation, given that Spanish is the second most common primary language among our patient population. We also revised the outreach message to include a Spanish explanation for changing the chatbot language to Spanish as preferred language in the EHR may not capture all appropriate patients. Finally, on July 30, 2024, we added screenshots about the chatbot outreach and content in the discharge paperwork for both birthing individuals and newborns to inform patients about the chatbot and address concerns that the chatbot outreach messages were potentially a scam.

Chatbot Reach Overall

A total of 6505 individuals out of 6684 birthing individuals (97.3%) discharged from the hospital successfully received the postpartum chatbot outreach message; those who did not receive it either had a landline phone number or did not have a working phone number or email in the EHR. Overall, 7489 out of 7525 caregivers (99.5%) successfully received the chatbot outreach message for each newborn. Less than 1% of recipients opted out of the chatbots. Approximately 63.3% of patients had a valid email (postpartum: 4107/6505 and newborn: 4757/7489), and 99.9% (postpartum: 6505/6505 and newborn: 7488/7489) had a valid phone number. A total of 6107 birthing individuals/caregivers received the postpartum and newborn chatbot messages, 398 birthing individuals only received the postpartum chatbot, 1076 unique caregivers only received the

XSL•FO
RenderX

newborn chatbot, and 298 caregivers received additional newborn chatbot messages for each newborn (due to multiparous, or births at different times; eg, 8 individuals had 3 newborns each during the project period).

Approximately two-thirds of recipients opened messages from either chatbot (Table 2). Newborn chatbot reach by experience ranged from 41.3% (3042/7373, experience 1) to 21.5% (1582/7373, experience 2), and the postpartum chatbot reach ranged from 34.5% (2243/6505, experience 1) to 10.2% (663/6505, experience 7; Table 1). Birthing individuals and caregivers who had a valid phone and email had a significantly higher chatbot reach (postpartum chatbot: 2980/4107, 72.6% and newborn chatbot: 3561/4756, 74.9%) than patients with only a valid phone number (postpartum chatbot: 1160/2398, 48.4% and newborn chatbot: 1372/2732, 50.2%). Only one caregiver had a valid email only and was not reached. For both chatbots, approximately 57% of users opened the messages by SMS text messaging only (postpartum: 2388/4140 and newborn: 2831/4933), 14% by email only (postpartum: 601/4140 and newborn: 678/4933), and 28% by both SMS text messaging and email (postpartum: 1151/4140 and newborn: 1424/4933).

[c]Reach is defined as the number of people who opened the chatbot link out of those who received outreach messaging.

[d]Chi-square statistics.

[e]N/A: not applicable.

[f]Data are only available through September 30, 2024.

[g]Data specific to newborn patients obtained from the electronic health record.

[h]Kaiser clinics are external clinics where both care and insurance are provided within the same system.

[i]FQHC: federally qualified health center.

Significant differences in reach were identified by age, ethnicity, race, preferred language, and insurance type across both chatbots (Table 2; all significant *P* values <.001). Birthing individuals who opened messages were more likely to be 30 years and older (2638/3910, 67.5%) compared to 29 years and younger (1502/2595, 57.9%), Hispanic (318/470, 67.7%) compared to non-Hispanic (2539/3937, 64.5%); White (713/940, 75.9%) compared to Black (1749/2926, 59.8%), had private insurance (1866/2670, 69.9%) compared to public insurance (1749/2941, 59.5%), and had prenatal care within the hospital's integrated health system (2148/2895, 74.2%) compared to external prenatal clinics (Kaiser patients 630/1234, 51.1%), other largely FQHC clinics (1072/1864, 57.5%), unknown prenatal care location (290/512, 56.6%). No significant differences in reach were found by the delivery method (ie, vaginal vs C-section).

Similarly, newborn chatbot caregiver reach was higher among birthing individuals who were 30 years and older (3075/4411, 69.7%) compared to 29 years and younger (1858/3078, 60.4%), White (823/1001, 82.2%) compared to Black (2217/3527, 62.9%), and had private insurance (2197/2955, 74.4%) compared to public insurance (2103/3498, 60.1%). Newborn chatbot reach was also higher when the newborn had a gestational age of 37 weeks or more (3881/5822, 66.7%) compared to a gestational age of less than 37 weeks (452/738, 61.3%), stayed in the hospital 2 - 4 days (2257/3304, 68.3%) compared to less than 2 days (1972/3070, 64.2%) and more than 4 days (704/1115, 63.1%), and had prenatal care within the hospital integrated health system (2380/3042, 78.2%) compared to external prenatal clinics Kaiser (721/1342, 53.7%), other largely FQHC clinics (1546/2609, 59.3%), and unknown prenatal care location (286/496, 57.7%). No significant differences were found for birth weight.

Postpartum Chatbot Analyses

In the final postpartum multivariate logistic regression model, we included age, race, preferred language, type of insurance, and prenatal location (Table 3). The odds of opening the postpartum chatbot were significantly lower for individuals identified in the EHR as Black (odds ratio [OR] 0.73, 95% CI 0.61- 0.88) compared to White individuals. Patients with a preferred language of "other" (OR 1.90, 95% CI 1.21-2.98) had greater odds of postpartum chatbot reach compared to English-preferring patients. Patients with public insurance (OR 0.72, 95% CI 0.64-0.82) and unknown insurance (OR 0.57, 95% CI 0.47-0.69) had lower odds of postpartum chatbot reach compared to individuals with private insurance. Patients who received prenatal care at clinics external to the hospital, including Kaiser clinics (OR 0.34, 95% CI 0.29-0.39), other

XSL•FO
RenderX

clinics (OR 0.52, 95% CI 0.45-0.60), or unknown clinics (OR 0.45, 95% CI 0.37-0.55), had lower odds of postpartum chatbot reach compared to patients who received prenatal care within the hospital integrated health system. Age was also a significant predictor, with each one-year increase in age associated with a 2% higher likelihood of chatbot reach (OR 1.02, 95% CI 1.01-1.03).

Table . Multivariate logistic regression for postpartum chatbot reach among birthing individuals discharged from the hospital between November 21, 2022, and January 15, 2025. Reach is defined as the number of people who opened the chatbot link out of those who received outreach messaging.

Characteristics	OR[a] (95% CI)	*P* value
Age (continuous)	1.02 (1.01-1.03)	<.001
Race		
White (reference)	N/A[b]	N/A
Black	0.73 (0.61-0.88)	<.001

Newborn Chatbot Analyses

For the final newborn multivariate logistic regression model, we included the birthing individual's age, race, insurance type, prenatal care location, and their newborn's time in the hospital (Table 4). Age was a significant predictor, with each one-year increase in age associated with a 2% higher likelihood of chatbot reach (OR 1.02, 95% CI 1.01-1.03). Birthing individuals who were listed in the EHR as Black (OR 0.61, 95% CI 0.50-0.74), other race (OR 0.73, 95% CI 0.59-0.91), and unknown race (OR 0.74, 95% CI 0.60-0.91) had lower odds of newborn chatbot reach than when the newborn's birthing individual was White. Patients with public insurance (OR 0.63, 95% CI 0.55-0.71), self-pay (OR 0.56, 95% CI 0.38-0.83), and unknown insurance (OR 0.58, 95% CI 0.48-0.69) had lower odds of reach than patients with private insurance. Patients who received prenatal care at clinics external to the hospital, including Kaiser clinics (OR 0.30, 95% CI 0.26-0.35), other clinics (OR 0.50, 95% CI 0.44-0.57), unknown clinics (OR 0.40, 95% CI 0.32-0.48), had lower odds of postpartum chatbot reach compared to patients who received prenatal care within the hospital health system. Finally, caregivers of newborns who stayed in the hospital for 2 - 4 days after birth (OR 1.21, 95% CI 1.09-1.35) had greater odds for chatbot reach compared to newborns who stayed in the hospital less than 2 days, but no significant differences were found for the newborns who stayed more than 4 days (OR 0.99, 95% CI 0.86-1.15).

[d]FQHC: federally qualified health center.

We conducted additional analyses limited to those where we had information on birthweight and gestational age (newborns discharged between October 2, 2022, and September 30, 2024). Birthing individual age, race, insurance, newborn time in the hospital, and prenatal care location remained in the model when including and excluding newborn birthweight and gestational age; ethnicity and preferred language were eliminated for both final models to fit the best model. Caregivers of newborns with very low birthweight (OR 2.44, 95% CI 1.32-4.50) had greater odds of opening the chatbot compared to newborns with normal birthweight, although no significant differences were found for the newborns with low birthweight (OR 1.11, 95% CI 0.88-1.39). In relation to gestational age, for newborns born at <37 weeks (OR 0.77, 95% CI 0.61-0.97), the caregivers were less likely to open the chatbot than caregivers with newborns born at term (37+ weeks). The ORs for other variables in the model were similar to those in the model with the full cohort that did not include birthweight and gestational age (Multimedia Appendix 2).

Chatbots Reach Changes Over Time

No significant changes in reach were found after launching the updated version of the newborn and postpartum outreach and chatbot content, nor after including the chatbot information in patients' discharge paperwork (Table 5); thus, we focused on results in the combined analyses for the full time period. We found significant improvements in reach for Spanish-speaking patients after deploying the Spanish version of the newborn chatbot (OR 1.42, 95% CI 1.03-1.96), but no significant differences in reach were found for the postpartum chatbot (OR 1.09, 95% CI 0.78-1.53). For a graphic description of the evolution of postpartum and newborn chatbots' reach over time (Multimedia Appendices 3 and 4).

[a]Reach is defined as the number of people who opened the chatbot link out of those who received outreach messaging.

[b]OR: odds ratio.

[c]Individuals discharged before January 9, 2024, for the postpartum chatbot and January 13, 2024, for the newborn chatbot were included in the analysis as the original content group, and individuals discharged between February 20, 2024, and January 15, 2025, for both chatbots were included in the new content group.

[d]N/A: not applicable.

[e]Only Spanish-speaking individuals identified in the medical record were included in the analysis. Individuals discharged before April 21, 2024, for the postpartum chatbot and April 25, 2024, for the newborn chatbot were included in the analysis as the pre-Spanish language group, and patients discharged from June 2, 2024, through January 15, 2025, were included in the Spanish-language group.

[f]Individuals discharged before July 29, 2024, were included in the analysis as before discharge paperwork, and individuals discharged from July 29, 2024, through January 15, 2025, were included in the discharge paperwork group.

Lessons Learned

This project highlighted the importance of involving stakeholders, including clinical staff, providers, patients, and community before and during the chatbot implementation to ensure acceptability, usefulness, and reach of the chatbot. The clinical teams were supportive of the rollout throughout the project. However, there were significant challenges in data collection and reporting from the third-party vendor, which may be better addressed in future work by working through specific needs, data accuracy, and various use cases for data before deploying the chatbot. Also, relying on a third-party vendor with ongoing expenses for hosting the chatbot limited the sustainability of this project after the project funding ended. Other health care systems or groups may consider options that are integrated into existing licenses so that ongoing fees are not prohibitive. Finally, given the design of the project and the vendor's limited capability to track individual level engagement with the program over time, we were unable to assess the impact of the chatbot on health outcomes.

Discussion

Principal Findings

This study describes strategies to develop a postpartum and newborn chatbot that was offered as standard of care for birthing individuals and caregivers of newborns discharged at a large hospital that serves a socioeconomically and racially diverse population. The chatbots' reach was close to two-thirds of the eligible birthing individuals and caregivers. Differences in reach were identified by age, race, prenatal care location, and insurance status for both chatbots, while newborn weight at birth, gestational age, and newborn time in the hospital were also significant predictors of the newborn chatbot reach. While disparities were present, this study demonstrated that chatbots have the potential to reach a significant proportion of this at-risk

XSL•FO
RenderX

population and elucidates opportunities to conduct additional targeted supports.

Previous commercial and research programs have shown satisfaction among those who choose to receive messages about maternal and infant care. In other large-scale programs such as Text4Baby, a national SMS text messaging strategy in the US, about 150,000 individuals have chosen to enroll annually to receive SMS text messaging about prenatal, postpartum, and infant health recommendations, with users reporting high satisfaction [8]. Other interventions have also shown that patients and caregivers report high satisfaction when receiving SMS text messaging with health recommendations about postpartum depression [19] and infant care [7]. Health chatbots are also positively viewed [20,21], and parents tend to appreciate the informational and emotional support provided by chatbots [21]. In addition to high acceptability, mHealth strategies are also effective in improving health behaviors. For example, mHealth strategies have been shown to be effective in infant emergency room visit reduction [7], blood pressure monitoring [22], prenatal and postpartum weight management [23], and smoking cessation [24], among others [25].

In this project, about 65% of the individuals opened the chatbots, suggesting interest in reviewing information about postpartum and newborn care. In a randomized control trial, patients who received Rosie, an AI chatbot for new mothers, found that 87% (13/15) of the users reported using the chatbot at least weekly [13]. Another study of a postpartum AI chatbot found that of the 290 enrolled patients in the study, 99% of the patients responded to the platform at least once, and 52% asked a question to the chatbot [26]. However, to our knowledge, there are no comparable standard of care for newborn and postpartum mHealth educational outreach strategies that have evaluated reach in real-world settings, underscoring the need for this work. Prior real-world behavioral interventions on various health topics have documented SMS text messaging reach ranging from 14% to 60% [27-29]; our findings thus surpassed expectations. For example, a study among smokers and at-risk drinkers found that a total of 14% of the patients clicked on the embedded link to the apps in the SMS text messaging [27]. Another project using EHR data to identify smokers found that 15% responded to the smoking cessation SMS text messaging program after a single recruitment text [28]. Another project for patients aged 65 years and older found that 60% of the patients responded to the COVID-19 vaccine SMS text messaging outreach strategy [29].

We found notable differences in chatbot reach by age, race, insurance type, and prenatal care location for both chatbots. Lower chatbot reach among younger patients, Black patients, patients with public insurance, and those who received prenatal care at clinics external to the hospital health care system may be attributed to differences in desire for information, disparities in health/technological literacy, concerns about data plans, or trust in the health care system or chatbots [29,30]. We were also unable to deliver the chatbot to patients without a valid email or cell phone number in the EHR. To improve equity, it is crucial to develop interventions that address these issues, whether through additional in-clinic outreach to inform patients and caregivers about the chatbot, ensuring a valid email and phone number is documented in the EHR before discharge, or improving patient access to health information via different channels (eg, phone calls, SMS text messaging, and community outreach). Costs to the health care system and potential models for covering such low-cost services should also be explored. Future research could also consider intentional partnership with community groups focused on Black birthing individuals and underserved populations to avoid disparities in chatbot implementation.

While significant changes to the chatbot content and strategies were made to improve the chatbot's reach, these strategies did not result in significant improvements. Similar findings were found in a prior study where no significant improvements in acceptability were found after intervention refinement based on participants' feedback [30]. Our study suggests that further research is needed to understand the drivers of chatbot reach post-hospital discharge, such as user experience and how outreach and content can be optimized to capture and retain user interest over time. Additional strategies, such as identifying the best outreach time of day, further tailoring the outreach messages/content, and potentially including AI for personalization [13] may play a role in how users access and engage with similar chatbots. Community-based approaches may also be useful for addressing concerns about chatbots and identifying ways to increase the attractiveness of chatbots to patients who experience disparities. In addition, these changes could potentially impact other areas of user experience that we did not measure, like usability, satisfaction, and engagement. Ongoing audit and feedback may also prevent gaps in study metrics and provide timely information on how patients are using these types of mHealth interventions.

Limitations and Strengths

In this study, patients did not have the opportunity to request that the chatbots be sent to their preferred contact information, which could have impacted reach. Furthermore, because our chatbot followed a rule-based system with fixed logic for user interaction, it did not allow patients to ask questions or review the information in their preferred order. While efforts were made to match the content to when patients might need this information, for some patients, the information presented in the chatbots might not have been relevant. Future integration of conversation AI is recommended to provide personalized responses; however, it needs to be done with caution to guarantee that patients are receiving accurate information.

Two-thirds of the birthing individuals and most newborns seek postpartum or newborn care, respectively, outside the system. Thus, we could not evaluate the impact on patient health outcomes. Even within our system, there was limited ability to link engagement with specific outcomes due to the variability in the ways that individuals could engage with the chatbot and view tailored information. Future longitudinal studies within an integrated health care system, through partnership across facilities or designed in a manner where relevant outcome data can be linked to specific aspects of chatbot engagement, are also needed to assess the impact of chatbot reach and engagement on maternal and infant health outcomes, such as postpartum depression, follow-up care, and visits to the

XSL•FO
RenderX

emergency room. Further research is also needed to understand patterns of reach related to gestational age, birthweight, or duration of hospital stay.

Despite these limitations, this study has many strengths. Delivering this program at scale provides unique information on who might engage with this type of digital outreach. This chatbot was intended to reach all patients and especially those who might not have a regular care provider to help them establish appropriate care. Finally, to our knowledge, our study presents the first example about chatbot reach to birthing individuals and newborn caregivers as standard of care within an urban hospital.

Conclusions

Our intervention demonstrated that chatbots can deliver important health information to many individuals efficiently, offering timely guidance on postpartum recovery, infant care, and follow-up appointments. These tools may serve as a supplement to patient care, helping bridge gaps in communication and support between health care providers and patients, especially for those who do not seek regular care. Understanding how constant interaction with digital health tools influences clinical outcomes, including a focus on racially and socioeconomically diverse populations, will help refine usability and effectiveness of these technologies.

Acknowledgments

We want to acknowledge the support of the DC Safe Babies Safe Moms Team, Doriun Brown, Christine Laccay, Dr Amalia Londono Tobon for reviewing the Spanish version of the chatbots, and Orbita, the company that ran the chatbots.

Funding

This project was funded by the A James and Alice B Clark Foundation. The funder had no involvement in the study design, data collection, analysis, interpretation, or the writing of the article.

Data Availability

The datasets generated or analyzed during this study are not publicly available because the data analyzed in this study could be used to identify patients. However, deidentified data obtained for this study will be made available (as allowable according to institutional review board standards) by emailing the corresponding author.

Authors' Contributions

JNRR wrote the first draft with input from HA. JNRR, MS, SM, and HA engaged in data collection, data curation, and analysis. JNRR and HA were responsible for study methodology, project administration, and supervision of the study team. KEA contributed to the development of the chatbot, and ADT contributed to the project conceptualization. All authors reviewed and edited the final article. There was no generative AI used in article writing.

Abstract

Background: Parents of young children with type 1 diabetes (T1D) are vulnerable to experiencing fear of hypoglycemia (FH), an emotional condition that includes persistent and intense worry about hypoglycemia and/or use of unhealthful behaviors to avoid hypoglycemia. Despite greater uptake of continuous glucose monitors (CGMs) and automated insulin delivery systems, FH remains prevalent and under-addressed in parents of young children. As such, we developed Reducing Emotional Distress for Childhood Hypoglycemia in Parents (REDCHiP), a video-based telehealth intervention designed to reduce FH in parents by providing T1D education and teaching parents how to apply evidence-based strategies from cognitive behavioral therapy and behavioral parent training in their child's daily T1D care.

Objective: This study aimed to compare the REDCHiP intervention to a novel attention control condition (ATTN) to better isolate treatment effects for REDCHiP based on parents' FH and diabetes distress.

Methods: This was a multisite randomized controlled trial. We enrolled 197 families and randomized 183 to either REDCHiP or ATTN. Both REDCHiP and ATTN parents completed 10 video-based telehealth sessions. Our primary outcome was changes in parental FH; secondary outcomes included changes in parental diabetes distress and children's glycated hemoglobin A_{1c} (HbA_{1c}). We used a series of mixed-effects models and logistic regression to evaluate treatment effects.

Results: Parents in REDCHiP and ATTN attended >95% of sessions with high treatment fidelity. FH and diabetes distress decreased significantly over time in both REDCHiP and ATTN. Treatment-slope effects slightly favored REDCHiP but were not statistically significant for FH (P=.09) or distress (P=.06). However, parents receiving REDCHiP were significantly less likely to report clinically elevated diabetes distress over time compared to ATTN (P=.02). Child HbA_{1c} showed a small, nonsignificant reduction over time (P=.06). Parents with elevated depressive symptoms consistently reported higher FH and distress across all time points.

Conclusions: REDCHiP demonstrated high feasibility, acceptability, and potential clinical relevance in reducing diabetes distress among parents of young children with T1D. While overall treatment effects were modest, use of an attention control condition represents a meaningful advancement in trial rigor for pediatric behavioral interventions. Future adaptations of REDCHiP may enhance its impact, particularly for parents experiencing comorbid depressive symptoms.

Introduction

Young children (<8 years old) living with type 1 diabetes (T1D) are particularly vulnerable to hypoglycemia due to heightened insulin sensitivity [1,2], unpredictable eating and exercise patterns [3], and challenges in recognizing and self-reporting symptoms of hypoglycemia [4]. Consequently, severe hypoglycemia occurs at nearly twice the rate in young children compared to older children and adolescents [5]. Parents, who bear primary responsibility for managing their young child's T1D regimen, are vulnerable to experiencing fear of hypoglycemia (FH) [4,6]. FH is a multisymptom emotional condition characterized by persistent and intense worry about the occurrence of hypoglycemia and/or reliance on unhealthful behaviors to avoid hypoglycemia (eg, treating normal glucose levels and underdosing insulin) [4]. FH affects up to 60% of parents of young children with T1D [4,7] and relates to lower quality of life [8,9], higher parenting stress [10], higher diabetes-related distress, and burnout, perhaps related to parents' experiencing a constant state of vigilance for hypoglycemic events [11].

Despite the high prevalence and negative impact of FH, there are few evidence-based interventions specifically designed to address this emotional challenge in parents of young children with T1D. To fill this gap, our team developed Reducing Emotional Distress for Childhood Hypoglycemia in Parents (REDCHiP) [12,13], a video-based telehealth intervention that merges principles of cognitive behavioral therapy and behavioral parent training with T1D education to help parents reduce their feelings of FH and their reliance on unhealthful hypoglycemia avoidance behaviors.

REDCHiP conceptualizes parents' FH as a specific phobia, which is readily treatable with cognitive-behavioral therapy [14,15]. Specifically, parents learn to identify unhelpful thoughts, feelings, and behaviors related to managing their child's T1D. Parents build a personal fear hierarchy of specific anxiety-provoking T1D-related situations and identify current maladaptive coping strategies that they desire to change. Parents then learn cognitive and behavioral strategies to help manage their fear while challenging themselves to gradually navigate fearful T1D-related situations or events differently (eg, response prevention). Finally, through imaginary and in vivo exposures, parents practice using the strategies they have learned to reduce feelings of FH [12].

Both individual and group treatment delivery appear effective when targeting anxiety [16] and providing behavioral parent training [17]. In the context of T1D education, group-based delivery is common [18]. REDCHiP combines individual and group treatment delivery so that parents can both receive personalized care during individual sessions and benefit from social support and the shared lived experiences of other parents of young children with T1D in the group sessions. In recent years, widespread uptake of video-based telehealth has transformed the delivery of pediatric behavioral interventions [19]. These platforms offer unique advantages for busy families, including less travel burden [20], flexible scheduling [21,22], and the ability for families to receive care in the home environment [21]. By designing REDCHiP for delivery via telehealth, we aimed to enhance its accessibility among parents of young children with T1D across diverse geographic locations.

To develop REDCHiP, we followed the Obesity-Related Behavioral Intervention Trials (ORBIT) model for behavioral treatment development [23]. This systematic approach to treatment development has multiple phases, each comprised of different preliminary studies designed to yield the incremental data necessary to increase the likelihood that the final treatment can influence a clinically meaningful target. In an earlier ORBIT Phase 2a study, we completed a waitlist-controlled pilot trial of REDCHiP [12] that included 36 families. We had high retention (86%), high session attendance (94%), and high parental satisfaction [24]. Moreover, our between-group comparisons demonstrated a significant reduction in FH for REDCHiP parents compared to waitlist parents, and once all parents had received REDCHiP, we found significant reductions in parents' FH and diabetes distress from pre- to posttreatment [12].

Thus, as a next step, we conducted an ORBIT Phase 2b study to better determine the source of our REDCHiP treatment effects [23]. Specifically, in a multisite randomized clinical trial (RCT), we compared our REDCHiP intervention to an attention control condition (ATTN). Our primary hypothesis was that parents randomized to REDCHiP would report greater reductions in FH compared to parents randomized to ATTN. However, we also explored changes in parents' diabetes distress as a secondary outcome, given its association with parents' FH and our pilot data, and we explored any reductions in young children's glycated hemoglobin A_{1c} (HbA_{1c}) following parental participation in REDCHiP or ATTN. If parents were purposefully engaging in behaviors to avoid the occurrence of hypoglycemia due to FH, we expected that HbA_{1c} could decrease among young children whose parents received REDCHiP versus ATTN. Here, we report the outcomes of our ORBIT Phase 2b trial of the REDCHiP intervention.

Methods

Study Design

This multisite RCT enrolled parents of young children with T1D from all regions of the United States through one of 3 recruitment sites located in the Southeast, Midwest, or Mountain regions of the United States. Our primary outcome was change in parental FH. Our secondary outcomes were change in parental diabetes distress and children's HbA_{1c}. We measured outcomes pretreatment, immediately post treatment, and 3-month post treatment, with the last assessment point intended to explore any maintenance effects.

Procedures

We recruited participants from 2019 to 2023; however, to comply with COVID-19 restrictions, we halted recruitment from March to July 2020. Additionally, due to slow recruitment, in August 2022, we expanded our efforts and launched a media campaign through the Type 1 Diabetes Exchange to advertise for the trial nationally. Our inclusion criteria were parents (including legal guardians) of young children with T1D, aged

XSL•FO
RenderX

2 - 6.99 years old, ≥6 months post diagnosis, and using intensive insulin therapy. We excluded parents if their child had a comorbid chronic condition (eg, renal disease), their child was allergic to the adhesive or skin preparation used for continuous glucose monitors (CGMs), their child was on conventional insulin therapy, or parents did not identify as English speaking. We did not restrict families based on the child's HbA_{1c}, though we required young children to be at least 6 months post diagnosis to allow for their HbA_{1c} to begin to stabilize following insulin initiation. We targeted parents who self-identified as primarily responsible for their child's daily T1D management to complete the treatment sessions and study questionnaires. However, parents who identified as a secondary caregiver for daily T1D management were also welcome to attend the treatment sessions, and multiple caregivers from the same family were able to participate together if preferred, though only one caregiver was included in our analyses.

We used both in-clinic and remote recruitment procedures. We screened all families who expressed an interest in participating in the trial for eligibility. After obtaining parent-informed consent, we randomized families 1:1 to either our treatment (REDCHiP) or ATTN. Families then completed visit 1, which included REDCap (Research Electronic Data Capture) [25] questionnaires and a measurement of child HbA_{1c} via a validated home kit, which was analyzed in a central lab. Families completed visit 2 at the end of the treatment phase and visit 3 approximately 3 months later. Visits 2 and 3 repeated the same study procedures as visit 1.

We compensated families for completing the study visits (US $35 per study visit). Parents received this incentive via a reloadable debit card (Clincard). We also gifted children a toy, valued at up to US $15, at each study visit as a thank you for completing the home HbA_{1c} kit.

Study Conditions

REDCHiP

Parents randomized to REDCHiP participated in 10 video-based telehealth sessions completed over a 12-week period [13]. There was a combination of individual and group sessions. Initially, parents attended 3 individual sessions and 7 group sessions. However, due to COVID-19 and scheduling challenges, we modified the format to 7 individual and 3 group sessions without changing content. Individual and group sessions typically lasted between 30 and 60 minutes each.

REDCHiP leaders included licensed psychologists, supervised psychology trainees, and a certified diabetes educator. They completed structured training in REDCHiP content and delivery, shadowed experienced leaders, and co-led sessions before leading sessions independently. They also received ongoing supervision from one of the designers of REDCHiP during intervention delivery to promote fidelity to the manual and consistent application of cognitive-behavioral strategies. For individual sessions, parents worked one-on-one with a REDCHiP leader, while group sessions brought together up to 5 parents and 1 - 2 trained REDCHiP leaders. We digitally recorded sessions and reviewed about one-third to code for treatment fidelity.

ATTN

Parents randomized to ATTN completed 10 video-based telehealth sessions over 12 weeks, matching REDCHiP in dose and format [13]. Initially, ATTN included 3 individual and 7 group telehealth sessions, but we later modified the schedule to 7 individual and 3 group sessions to remain consistent with REDCHiP. Individual and group sessions lasted 30 - 60 minutes.

ATTN leaders included supervised psychology trainees and clinical trials assistants. They completed structured training in ATTN content and delivery, shadowed experienced leaders, and co-led sessions before leading independently. During the sessions, parents learned content relevant to all parents of young children, such as important developmental milestones, child health and safety, school readiness, early childhood literacy, and positive parenting strategies. Leaders redirected any T1D-related questions to the child's T1D care team. We digitally recorded sessions and reviewed about one-third to code for treatment fidelity.

Measures

Families randomized to REDCHiP or ATTN completed the same online questionnaires, and young children completed a validated home HbA_{1c} kit. We previously published a description of our trial battery [13]. For this report, we focus on describing our sample characteristics and examining treatment effects based on changes in parent FH and diabetes distress and child HbA_{1c}.

Family and Children's T1D History

In visit 1, parents completed a study-specific questionnaire to describe themselves (age, sex, relationship to the child, race and ethnicity, marital status, and highest grade completed) and their child (age, sex, race and ethnicity, date of T1D diagnosis, T1D treatment regimen, and history of severe hypoglycemia).

Hypoglycemia Fear

At all study visits, parents completed the 22-item Hypoglycemia Fear Survey-Parents of Young Children (HFS-PYC) [6], which measures FH based on worries and the frequency of hypoglycemic avoidance behaviors. Parents respond to items using a 5-point Likert scale (1=Never to 5=Very Often), with higher scores indicating greater fear. In line with published scoring recommendations, we removed 4 items with poor performance for young children on intensive insulin therapy, resulting in a modified initial total score (range=22 - 110). To enhance interpretation, we rescored the HFS-PYC to fit a 0 - 100 scale by calculating the item mean score and multiplying by 20.

Diabetes Distress

At all study visits, parents completed the 18-item Problem Areas in Diabetes-Parent Revised (PAID-PR) [26], which is a validated measure of parent-reported diabetes distress. Parents respond to items using a 5-point Likert scale (0=Not a problem-4=Serious problem). The PAID-PR scoring uses a 0 - 100 scale with higher scores indicating greater distress. Additionally, a total score ≥56 may indicate the presence of significantly elevated diabetes distress [27].

XSL•FO
RenderX

Depressive Symptoms

At all study visits, parents completed the 20-item Center for Epidemiological Studies Depression Scale-Revised (CESD-R) [28,29], which is a measure of depressive symptoms over the past 2 weeks. Parents respond to items using a 5-point Likert scale (0=Not at all-4=Nearly every day). Based on normative data, a total score ≥16 suggests elevated depressive symptoms [29]. We dichotomized parent depressive symptoms, categorizing CESD-R scores ≥16 as "elevated depressive symptoms" and scores <16 as "non-elevated symptoms." We included the presence of elevated depressive symptoms as a covariate in all models because of its known association to FH and distress in the extant literature [30,31].

Child HbA_{1c}

At all study visits, children completed a validated home HbA_{1c} kit [32] to obtain a proxy measure of children's average glycemia using a finger-prick blood sample. We analyzed the samples in a single laboratory using automated high-performance liquid chromatography with measurement methods reliable to Diabetes Control and Complications Trial standards (reference range 4.0% - 6.0%; Tosoh 2.2; Tosoh Corporation) [33].

Sample Size and Power

We conservatively based our original power analysis on the assumption of completing 40 groups (20 REDCHiP and 20 ATTN) with an average size of 3.6 parents (40×3.6=144, or a final sample of n=144 parents). Based on this sample size, a standardized effect size of 0.4 SDs, and an intraclass correlation of 0.10, we projected an estimated power of 85%. We originally estimated an attrition rate of 20%, thereby setting our target sample size at 180 families. However, during the trial years affected by COVID-19, we experienced a higher rate of attrition. Thus, to account for this higher attrition rate, we over-recruited for the trial; our final sample comprised 197 families.

Statistical Analyses

To compare families randomized to REDCHiP or ATTN based on sociodemographic characteristics collected at visit 1, we used independent 2-tailed *t* tests, chi-square tests, or 2-sample Wilcoxon rank-sum tests for nonnormally distributed variables. Because preliminary analyses indicated correlations between parent depressive symptoms and both FH and distress, we elected to include the presence of elevated parental depressive symptoms as a covariate in all our models to better isolate treatment effects. To examine reductions in parents' FH (primary outcome), we ran a mixed effects model with participant as a random effect and fixed effects for randomization (REDCHiP or ATTN), visit (slope of the respective outcome over the study timeline), and the interaction of randomization by study timeline. For diabetes distress (secondary outcome), we repeated the mixed effects model when analyzing distress as a continuous variable. We conducted a logistic regression to analyze distress dichotomously (elevated vs not elevated) as a sensitivity analysis to examine whether parents were less likely to report clinically elevated distress over time based on an established threshold, using the same random effect structure and covariate. In exploratory analyses, we examined reductions in child HbA_{1c} by repeating the mixed effects model. We conducted all analyses in StataNow/SE 18.5 (StataCorp LLC). Because our hypotheses were directional and prespecified, we applied one-sided *P* values to test for changes in the expected direction. We did not adjust for multiplicity because we designed the trial as an ORBIT Phase 2b study exploring treatment effects rather than providing definitive efficacy estimates [23]. Consistent with CONSORT (Consolidated Standards of Reporting Trials; Checklist 1) reporting guidelines [34], we report estimates of effect sizes for observed treatment-slope trends based on the methods described by Feingold [35] to aid interpretation of the magnitude of change; they should not be interpreted as evidence of statistical significance.

Ethical Considerations

We operated this multisite RCT under a single institutional review board (IRB) agreement, with Children's Mercy Hospital-Kansas City as the IRB of record. We used IRB-approved procedures to obtain electronic documentation of parent informed consent before enrolling parents into the trial. All children were younger than 7 years; therefore, we did not require separate child assent. We registered the trial on ClinicalTrials.gov (NCT3914547) before proceeding with any trial activities. We collected and managed study data using secure, password-protected systems and deidentified all data prior to analysis. Participation involved minimal risk, and parents could skip questionnaire items or withdraw from the study at any time without penalty. We compensated participants for their time.

Results

Sample Characteristics

We enrolled 197 families of young children with T1D and randomized 183 families (n=93 to REDCHiP and n=90 to ATTN). At visit 1, we collected parent and child demographics. Young children had a mean age of 4.4 (SD 1.2) years, a mean HbA_{1c} of 7.54% (SD 1.15), and a mean time since diagnosis of 1.67 (SD 1.15) years. Children were 55% (100/183) male. Parents had a mean age of 36.3 (SD 5.9) years and 93% (170/183) self-identified as the child's mother. Table 1 displays sample characteristics and comparisons by group. The CONSORT table details our recruitment and retention across the seven-and-a-half-month trial (Figure 1). Of the total enrolled, 77% (152/197) of families completed all study visits.

Intervention Characteristics

Overall, parents randomized to REDCHiP attended 95.2% of sessions, and parents randomized to ATTN attended 95.9% of sessions. While there was no difference in the mean length of group sessions for the REDCHiP and ATTN arms (*P*=.22), there was a difference in the mean length of individual sessions for the REDCHiP and ATTN arms (*P*=.003). Specifically, individual sessions in the REDCHiP arm were on average 7 minutes longer in duration than individual sessions in the ATTN arm (mean 39.6, SD 4.2 vs mean 32.7, SD .7 minutes for REDCHiP and ATTN, respectively). We coded treatment fidelity for 170 out of 517 (33%) of ATTN sessions and 199 out of 532 (37%) of REDCHiP sessions using structured, session-specific checklists. Overall, both arms achieved a high treatment fidelity rate (85/100, 85% for ATTN and 89/100, 89% for REDCHiP).

Survey Outcomes

Table 2 describes outcomes for parent FH, diabetes distress, and the percentage of parents with clinically elevated depressive symptoms for the entire sample and within each treatment arm. Across both arms, parent FH, diabetes distress, and the percentage of parents with clinically elevated depressive symptoms decreased from visits 1 to 3. However, at all study visits, parents with clinically elevated depressive symptoms reported higher FH and distress than parents without clinically elevated depressive symptoms (*P*=.001; Table 3).

Table . Survey outcomes at each time point by group.

Overall	REDCHiP[a]			ATTN[b]		
	Visit 1	Visit 2	Visit 3	Visit 1	Visit 2	Visit 3
Hypoglycemia fear, mean (SD)	55.44 (13.42)	49.43 (10.95)	46.89 (9.46)	57.43 (14.38)	53.30 (13.24)	51.75 (12.02)

Hypoglycemia fear	55.48 (11.36)	47.57 (10.36)	.001
Diabetes distress	49.16 (16.23)	26.35 (15.32)	.001

Mixed Effects Models

In a series of mixed effects models, we examined treatment effects for parents' FH and diabetes distress, with randomization (REDCHiP or ATTN), visit (slope of the respective outcome over study timeline), interaction of randomization by study timeline, and presence of elevated depressive symptoms as covariates. In our first model, results revealed that parents' FH decreased over time for both treatment arms (coefficient=−2.57; 95% CI −3.81 to −1.33; *P*=.001), with a treatment-slope effect that slightly favored the REDCHiP group, though it was not significant (coefficient=−1.16; 95% CI −2.88 to 0.57; *P*=.09). Similarly, in our second model, results revealed a decrease in parents' diabetes distress over time for both treatment arms (coefficient=−3.93; 95% CI −5.63 to −2.23; *P*=.001), with a nonsignificant treatment slope effect (coefficient=−1.87; 95% CI −4.23 to 0.50; *P*=.06) that slightly favored the REDCHiP group. Although the interaction terms were not statistically significant, we calculated effect sizes to describe the magnitude of observed trends in accordance with CONSORT recommendations [34]. For parents' FH, the effect size for REDCHiP was Feingold d=0.18, and for diabetes distress, the effect size for REDCHiP was Feingold d=0.21.

XSL•FO
RenderX

Logistic Regression

We also examined treatment effects for parents dichotomized as having either clinically elevated or not elevated diabetes distress, with randomization (REDCHiP or ATTN), visit (slope of the respective outcome over the study timeline), interaction of randomization by study timeline, and presence of elevated depressive symptoms as covariates. There was no time effect (coefficient=−0.25; 95% CI −0.61 to −0.11; *P*=.08). However, we observed a significant treatment-slope effect (coefficient=−0.70; 95% CI −1.35 to −0.05; *P*=.02), suggesting that, over time, REDCHiP parents were less likely to endorse clinically elevated diabetes distress.

Glycemic Outcomes

In mixed effects models, we explored treatment effects for children's HbA_{1c}, with randomization (REDCHiP or ATTN), visit (slope of the respective outcome over study timeline), interaction of randomization by study timeline, and presence of elevated depressive symptoms as covariates. Results revealed a small but nonsignificant reduction in child HbA_{1c} over time for both treatment arms (coefficient=−0.05; 95% CI −0.12 to 0.03; *P*=.11), with a nonsignificant treatment-slope effect for children of parents in the REDCHiP group (coefficient=0.04; 95% CI −0.06 to 0.15; *P*=.21).

Discussion

Overview

Our aim was to examine the source of treatment effects for REDCHiP, a telehealth-delivered intervention to reduce FH in parents of young children with T1D, by conducting an RCT. We recruited a large sample of parents from across the United States and randomized them to receive either REDCHiP or an attention control treatment (ATTN). We hypothesized parents receiving REDCHiP would report greater reductions in FH and diabetes distress compared to parents who were randomized to ATTN. We also explored whether children experienced an HbA_{1c} reduction based on parents' exposure to REDCHiP or ATTN.

Primary Results

Contrary to our primary hypothesis, our results suggest that all participating parents experienced significant reductions in FH with treatment-slope effects that slightly favored REDCHiP parents and were nonsignificant (*P*=.09). When we examined parents' diabetes distress as a secondary outcome, our model with diabetes distress as a continuous variable showed a similar time and treatment slope effect (*P*=.06). However, the model analyzing diabetes distress as a dichotomous variable identified a significant treatment-slope effect for REDCHiP. Specifically, we found that parents receiving REDCHiP were less likely to report clinically elevated diabetes distress over time than parents receiving ATTN (*P*=.02). Our results also suggest a small and nonsignificant decrease in children's HbA_{1c} over time, regardless of intervention group.

Although both REDCHiP and ATTN were associated with reductions in FH and diabetes distress, the reasons for improvement in the ATTN group remain unclear. ATTN sessions did not include content on emotional regulation or stress management, and there is limited evidence that general support groups reduce anxiety or depressive symptoms in adults [36]. One possibility is that nonspecific factors, such as social connection during sessions (especially surrounding the COVID-19 pandemic), contributed to improvements, though this is only speculative and would require further dismantling studies to confirm. Importantly, we designed ATTN as a comparator versus its own scalable intervention. Furthermore, it is unknown whether a longer follow-up post treatment would reveal greater divergence between groups. In a context where virtually no interventions exist to address FH in parents of young children with T1D, we believe the observed reductions, even if nonsignificantly different by condition, represent an important step forward in the field.

While there is an emerging trend in testing new behavioral interventions uniquely tailored to parents of young children with T1D, the literature remains small compared to parents of older children with T1D [37]. As such, we believe this trial adds valuable insight into how to support parents of young children with T1D in managing symptoms of FH and diabetes distress. Moreover, because this is the first behavioral intervention trial among parents of young children with T1D to use an attention control arm, we assert that it marks a notable improvement in trial design rigor directed at families of young children with T1D [38,39].
